ATLANTIC INTRACOASTAL WATERWAY, a protected route paralleling the Atlantic coast, from Massachusetts bay to Key West, Fla., comprises a number of natural and artificial waterways. Portions are used by deep-draft vessels. The route, which utilizes sounds, bays, lagoons, rivers and canals, was planned eventually to connect, by canals across Florida, with an extension of the Gulf Intracoastal waterway, forming a continuous 3,000-mi. protected waterway. The entire route is toll free.

Between Massachusetts bay and Buzzards bay, Massachusetts, the Atlantic Intracoastal waterway is through the Cape Cod canal, a sea-level canal 17.5 mi. long, with a project depth of 32 ft. at mean low water and width of 450 ft. It was purchased from a private company by the federal government in 1927 for $11,500,000, and subsequently deepened and enlarged. The canal is heavily used by ocean-going vessels between coastal ports. During the 1960s, annual traffic was between 10,000,000 and 12,000,000 tons, including 4,000,000 tons of foreign traffic and 3,500,000 tons of coal eastbound to New England.

From Buzzards bay at the southwestern end of the canal, the route proceeds through Block Island and Long Island sounds, the East river and New York harbour to Sandy Hook, New Jersey. South of Sandy Hook vessels must move in the open ocean to Delaware bay at Cape May, although small pleasure and fishing craft may use the 113 mi. of waterways behind the coastal barrier beach south of Manasquan inlet, 20 mi. south of Sandy Hook.

From Cape May, the route crosses Delaware bay to the Chesapeake and Delaware canal; originally privately owned with locks, the canal was purchased by the federal government in 1919 and converted to sea level. Although the project called for deepening to 35 ft., maximum vessel draft that could traverse the canal was 25 ft. in the 1960s.

The canal shortens the distance for ocean-going ships between Baltimore and ports to the north. Traffic amounts to about 10,-

000,000 tons annually, about half of which is foreign. Southward from the Chesapeake and Delaware canal, the route follows Chesapeake bay for about 170 mi. to Norfolk, Va.

The Atlantic Intracoastal waterway proper extends 1,134 mi. from Norfolk, Va., to Key West, Fla. For most of that distance, it follows coastal rivers and lagoons, behind barrier beaches which protect it from the sea. Unlike sections to the north, the waterway south of Norfolk carries relatively little commercial traffic—from 50,000 to 100,000 tons of barge traffic annually. Principally for pleasure craft, it is completely protected from the sea and connects populous northern metropolitan areas with resort areas of Florida. During World War II the route became important as a means of avoiding the submarine menace along the coast.

The limiting depth for the entire route is in the Dismal Swamp canal, which extends 22 mi. between Deep Creek, Va., and South Mills, N.C. This canal has a controlling depth of 6.1 ft., and at each end has a lock with a lift of 12 ft.

The Dismal Swamp canal was originally planned in 1763 when George Washington conducted surveys and was opened in 1828. Surveys were authorized by congress in 1837 to determine feasibility of a protected route from the Dismal Swamp canal to Charleston, S.C. Another survey was made in 1875, but actual work on the waterway proper, south of the Dismal Swamp canal, was begun in 1911. The final link between Norfolk and Key West was opened in April 1936, between Little river and Winyah bay, South Carolina.

After World War II, the vertical clearance of the many bridges across the route became a major issue. Frequent openings of the drawbridges caused serious delays in heavier motor traffic to and from shore line communities on the barrier beaches, resulting in a movement for fixed bridges. Commercial and yachting interests favoured bridges with relatively high clearances to permit passage by masted vessels; highway interests favoured lower fixed bridges to avoid costly construction of high-level approaches.

ATLÁNTICO, a department of the republic of Colombia, bounded on the north by the Caribbean sea, on the east by the Magdalena river (*q.v.*) and on the south and west by the Dique canal, a navigable distributary of the Magdalena. The bifurcation of the Magdalena in effect makes of Atlántico an island surrounded by river flood plains except that a small part of the department of Bolívar is included within the "island." Although it is the smallest of the departments of Colombia (1,333 sq.mi.), Atlántico's strategic geographic position at the mouth of one of the continent's major rivers has given it an importance greater than its area suggests. Three-fourths of the population of the department (1961 est., 612,170) live in the capital city of Barranquilla (*q.v.*), one of Colombia's most active ports, 15 mi. upriver from the mouth of the Magdalena. Despite a long dry season, rural population density is high; cotton and sesame are the principal commercial crops. (Js. J. P.)

ATLANTIC OCEAN, the name given to the vast stretch of sea dividing the continents of Europe and Africa from the new world. The term is supposedly derived from Atlantis, presumed to be a submerged continent below the present ocean. For the relation of the Atlantic to other oceans and detailed explanation of phenomena common to all oceans, *see* OCEAN AND OCEANOGRAPHY.

Extent.—The Arctic basin which stretches from Bering strait across the north pole to Spitsbergen and Greenland belongs essentially to the Atlantic ocean, as in the south does the Weddell sea, south of South Georgia. The utilization of the Arctic and Antarctic circles as boundaries has neither geographical nor physical justification. The Atlantic ocean has, therefore, a share in both the seas of ice. From a consideration of winds, currents and temperature it is best to count the equatorial boundary of the North Atlantic at about latitude 5° N. In contrast to the South Atlantic it is rich in islands, in variety of coast line and in tributary seas. The latter include the Caribbean sea, the Gulf of Mexico, the Gulf of St. Lawrence, Hudson bay, Baffin bay on the west, and the Mediterranean sea, Black sea, North sea and Baltic sea on the east. Between Spitsbergen and Novaya Zemlya on the one hand and the Murmansk coast on the other lies the Barents sea; between Spitsbergen, Iceland, the Faeroes, Shetlands and Norway lies the Norwegian sea. The southern outlets from the Arctic basin are relatively narrow. Hudson strait is 64 mi. broad, Davis strait 200 mi., Denmark strait between east Greenland and Iceland 159 mi. and the passage between Iceland and north Scotland 518 mi. In the South Atlantic on the other hand, between Cape Horn and South Africa, the South Atlantic approaches Antarctica on a 3,965 mi. front, and is much colder and rawer than the North Atlantic. The Atlantic is, broadly, S-shaped and narrow in relation to its length, with the result that writers have spoken of an Atlantic valley. From the Bering strait in the north to Coats Land in the south the distance is 12,810 mi. The breadth from Newfoundland to Ireland is 2,059 mi. and from Capo Saõ Roque, Braz., to Cape Palmas, Africa, only 1,769 mi. Southward from these latter it becomes broader and is bordered by simple coasts almost without islands. Drake passage, between Cape Horn and the South Shetlands, is a strait 541 mi. wide into the South Pacific. E. Kossinna reckoned the area of the Atlantic without its dependent seas at 31,814,640 sq.mi. and with its dependent seas at 41,081,040 sq.mi. By comparison, the North sea has an area of 220,000 sq.mi. Although not the most extensive of the great oceans the Atlantic has by far the largest drainage area. The "long slopes" of the continents on both sides are directed toward the Atlantic, which accordingly receives the waters of a large proportion of the great rivers of the world, including the St. Lawrence, the Mississippi, the Orinoco, the Amazon, the rivers of La Plata, the Congo, the Niger, the Loire, the Rhine, the Elbe and the great rivers of the Mediterranean and the Baltic. Sir J. Murray estimated the total area of land draining to the Atlantic to be 13,432,000 sq.mi., or, with the arctic area, nearly 16,691,000 sq.mi., nearly four times the area draining to the Pacific ocean, and almost precisely four times the area draining to the Indian ocean.

Islands.—Among purely oceanic islands without a foundation of continental rock, usually the result of volcanic action, there are Jan Mayen Land Iceland, Fernando de Noronha (near Capo Saõ Roque), Ascension, St. Helena, Tristan da Cunha and Bouvet Islands (54° 10′ S. lat.). Mainly volcanic, but with a continental type foundation are the Azores, Canaries, Madeira and Cape Verde islands Purely continental are Spitsbergen and the Bear Islands, the British Isles, Newfoundland, the Great Antilles, the Falkland Islands, South Georgia and the South Orkneys. The Bermudas (30° N. lat.) are the most northerly coral-reef islands of the world. All Atlantic islands of purely oceanic origin together have an area of 43,000 sq mi. In this connection it seems best to consider Greenland as a part of the North American continent

(G. Sc.; C. A. Bs.)

Relief of the Ocean Floor.—The foundations of knowledge of the Atlantic floor were laid during the latter half of the 19th century. Numerous scientific expeditions, such as those of the H.M.S. "Challenger" (1872–76), the German ship S M.S. "Gazelle" (1874–76) and the surveying vessel the U.S.S. "Blake" (1877 and later), contributed to these early studies. In the 20th century the scientific upsurge beginning with World War II, and further stimulated during the International Geophysical year (IGY) of 1957–58 vastly expanded knowledge of the oceans. The greatest impetus to the early investigations was the need of information on the character of the sea bottom for the laying of transatlantic cables. Surveys made prior to and during the laying and repair of these submarine cables led to a fairly good understanding of the large-scale features of the bottom topography. Explorations in the arctic and antarctic at about the beginning of the 20th century provided information from high latitudes. The next stimulus to the study of the deep-sea topography arose from the invention of sonic depth finders (echo sounders) which came into general use about 1925. The generalized features of the sea bottom, based on relatively few soundings, taken by sounding weight and wire were found to be much oversimplified in light of the millions of echo soundings which were made after 1925. Despite the ease and rapidity with which echo soundings can be taken there are still vast areas in the Arctic and South Atlantic oceans that are but poorly surveyed. The installation of echo sounders as standard

equipment on all vessels introduced an additional aid to navigation where accurate bathymetric charts are available; consequently accurate surveys of coastal waters are made out to depths of about 13,000 ft. This program in the Atlantic aroused great interest in the character and origin of the continental shelves and slopes and provided information on the history and formation of these features. Beyond the slopes numerous sea mounts were discovered.

The floor of the Atlantic is divided into the eastern and western troughs by the Atlantic ridge, a tremendous elevation extending from the vicinity of Iceland to Bouvet Island. In the troughs depths exceed 16,000 ft., but the ridge is continuous at depths less than 10,000 ft. for the greater part of its length and in several places extends above sea level. The islands of the Azores, St. Paul, Ascension, Tristan da Cunha and Bouvet rise from the ridge. There is one small but oceanographically important break in the ridge in the Romanche furrow just north of the equator where the saddle depth is about 15,000 ft. The transverse Walfisch ridge, which extends northeast from the vicinity of Tristan da Cunha (37° S. lat.) to the coast of Africa in latitude 20° S., is continuous at depths of slightly more than 10,000 ft. and divides the eastern trough. An analogous feature, the Rio Grande ridge,

extends from the Atlantic ridge to South America in latitudes 30°–35° S. but is deeper and continues only at depths greater than 13,000 ft. These major structures have a pronounced effect on the deep-water circulation and, hence, on the temperature and other conditions at great depths.

Within the eastern and the western troughs are a number of more or less discrete basins in which depths exceed 13,000 ft. and usually 16,000 ft. In the Puerto Rico trough in the Guiana basin, the U.S.S. "Milwaukee" obtained a sounding of 30,246 ft., the greatest depth thus far found in the Atlantic. A maximum depth of 27,108 ft. has been obtained in the South Sandwich trench, an arcuate structure bordering the eastern side of the South Sandwich Islands. The basins bear geographic names.

The north polar basin and the intervening Norwegian basin are separated from the open Atlantic by a ridge extending from Greenland to Scotland upon which Iceland and the Faeroe Islands rise above sea level. The maximum depths in Denmark strait, between Greenland and Iceland, and over the Wyville-Thomson ridge, between the Faeroes and Scotland, are only about 1,600 ft. A lowering of sea level of about 1,600 ft. would impose a land bridge from North America to Europe and completely isolate the waters of the polar basin from both the Atlantic and the Pacific. In the north polar basin there were relatively few soundings until the Russian expedition (1937–38) which landed by plane on the ice within 60 mi. of the pole. After that time numerous soundings were made from the ice floes and ice islands throughout the basin. The basin, roughly elliptical, is divided into two parts by the Lomonosov ridge, having a sill depth of 5,000 ft., which runs from the continental shelf north of Ellesmere Island through a position of 89° N. 180° W. then south near the meridian of 140° E. toward the New Siberian Islands. The depression on the right looking north from Ellesmere Island is smaller but deeper, over 16,000 ft., whereas depths in the larger basin to the left (toward Alaska) approach 13,000 ft. There are two lobes in the larger basin and some evidence of a second ridge roughly parallel to the Lomonosov ridge. On the Greenland-Spitsbergen ridge the sill depth is about 5,000 ft. and in the Norwegian basin the greatest depth is about 12,000 ft.

Depths greater than 13,000 ft. occur in the Caribbean basin and in the Mediterranean sea. The former has numerous shallow and several deep connections with the open ocean, but the Mediterranean communicates with the Atlantic only through the Strait of Gibraltar, which is 12.2 mi. wide and where the maximum depth on the sill is only 1,000 ft. The partial isolation of the large adjacent seas has a profound effect on the conditions in the seas and also upon those in the open ocean. The topography in the Caribbean area is extremely rugged with deep trenches adjacent to steep-side ridges, many of which rise above sea level. The Milwaukee depth of 30,246 ft. is close to the northern side of Puerto Rico and in the Bartlett deep south of Cuba the U.S.S. "S-21" obtained a maximum sounding of 23,748 ft.

The mean depth of the Atlantic ocean, excluding adjacent seas, is, according to Kossinna (1921), 12,880 ft., or, including them, 11,000 ft. These values are somewhat less than corresponding values for the Pacific and the Indian oceans and are attributed to the extensive shelves with depths less than 650 ft. deep in the higher latitudes of the North Atlantic and in the Arctic oceans. Depths less than 650 ft. represent 13.3% of the Atlantic and adjacent seas, between two and three times their relative extent in the other oceans.

Bottom Deposits.—For the general characteristics of bottom deposits *see* OCEAN AND OCEANOGRAPHY: *Marine Sediments*. The greater part of the bottom of the Atlantic between the Arctic and the Antarctic circles is covered with globigerina ooze. At depths greater than 16,500 ft. the calcium carbonate content decreases and the calcareous deposits give way to red clay. On the submarine ridges the finer material is lacking and the shells of pteropod mollusks are sometimes sufficiently abundant to characterize the deposits as pteropod ooze. Diatom ooze is the most widespread deposit in the high southern latitudes but, contrary to conditions in the Pacific, is not found in northern latitudes. There is 73% of the main basin of the Atlantic (*i.e.*, including adjacent seas)

covered by pelagic sediments, globigerina and pteropod oozes covering 16,062,000 sq.mi. (50%); red clay, 6,139,000 sq.mi. (19%); and diatom ooze 1,583,000 sq.mi. (5%). The remaining 26% of the Atlantic and all adjacent seas are covered with terrigenous sediments characterized by relatively coarse mineral fragments of terrestrial origin. Air-borne material is abundant off the west coast of Africa where dry offshore winds carry material from the desert regions. In high latitudes ice-borne debris is a characteristic component of the deposits. Pebbles and rock fragments, sometimes showing the effects of glacial abrasion, are common in the tracks of the icebergs. The calcium carbonate content of the sediments of the Atlantic is notably higher than that in comparable depths and latitudes in the North Pacific. This situation is apparently related to the different conditions in the overlying water.

The German "Meteor" expedition (1925–27) collected numerous core samples in the tropical and South Atlantic. Samples up to 10 ft. long were obtained in 1936 by the cable ship "Lord Kelvin" on a line between Newfoundland and Ireland, and since World War II thousands of cores, some exceeding 50 ft. in length, have been collected, mostly from the North Atlantic. The sediments are more or less stratified, implying varying rates of accumulation of the various components. In some areas in the North Atlantic this is indicated by concentrations of volcanic ash or ice-borne terrigenous material. In lower latitudes there are changes in the relative abundance of different types of pelagic foraminiferal remains. This is interpreted as the result of changed water temperatures. Using the topmost layers characterized by cold-water fossils or abundant glacial debris as indicators of the most recent glacial period, it has been possible to estimate the rates of deposition of deep-sea sediments. In the second half of the 20th century increasing use was being made of radioactive dating. Estimates indicate that the pelagic sediments in the Atlantic are accumulating at a rate of about 1 or 2 cm. per 1,000 years.

Meteorology.—The large-scale wind system over the North Atlantic is directly related to the average distribution of atmospheric pressure of which the two major features are the Azores "high" and the Iceland "low." In the northern hemisphere the winds blow clockwise around a high-pressure area and counterclockwise around a low-pressure area. The prevailing winds on the equatorial side of the Azores high are therefore northeasterly to easterly. Since the pressure distribution remains nearly unaltered during long periods these winds, the trade winds, blow with a great constancy, particularly in winter when their regime extends farthest north. Between the Azores high and the Iceland low, westerly winds prevail. They are weak in summer and strong in winter, and on approaching northwestern Europe they assume a more southeasterly direction and bring warm and moist air to that part of the European continent. On the northern side of the Iceland low, along the east coast of Greenland and in the Labrador sea, winds with a northerly component are the more frequent.

The Iceland low is well-developed in winter only, but it is not so permanent a feature as the Azores high. Over the middle latitudes of the North Atlantic traveling lows (cyclones) develop which advance from west to east with southerly winds on their eastern side, northerly on the western. Some of these continue toward the northeast and pass over northern Norway, whereas others cross the British Isles, the Low Countries and Germany.

Over the tropical part of the North Atlantic the air temperature is throughout the year slightly lower than the surface temperature of the water, but the average difference is only about 0.8°. In winter large differences between air and sea-surface temperature are found in middle and higher latitudes and are related to the direction of the wind. Polar continental air often spreads from the North American continent over the adjacent part of the North Atlantic. This air is very cold and although it is rapidly heated when it comes in contact with the warmer water, its temperature hundreds of miles off the coast may still be 5° to 10° C. below that of the water surface. Under these conditions excessive evaporation occurs because the cold air has a low moisture content and the vapour pressure in the air is much lower than that at the warm sea surface. Over the western North Atlantic even the average air temperature is in winter considerably lower than the water temperature, and by far the greater amount of evaporation takes place in this season and not in summer, as is commonly believed. On the other hand, where warm air blows over cold water the air is cooled and the moisture in the air condenses, forming fog. This process accounts for the high frequency of fog over the Grand Banks of Newfoundland in spring and early summer when southerly winds carry warm air over the cold waters covering the banks. From July to September the air temperature differs little from that of the water.

Over the South Atlantic a high-pressure area is found between latitudes 20°–30° S., corresponding to the Azores high. On the equatorial side of this high the southeast trade wind blows weakly during the southern summer and strongly during the northern winter. Between the southeast trade winds and the northeast trade winds of the northern hemisphere lies the equatorial calm belt, the doldrums, which generally is located in the northern hemisphere between 2° and 10° N. The calm belt, characterized by light winds and heavy downpours, is generally absent off the coast of South America where the two trade winds join and blow strongly against the north coast of Brazil. In the southern hemisphere there is no counterpart of the Iceland low but a belt of low pressure surrounds Antarctica, and between this low-pressure region and the high in lat. 20°–30° S. westerly winds prevail. These westerlies which often reach gale force are particularly strong in latitudes 35°–45° S., the roaring forties.

The Benguela coast of southwest Africa is noted for its fog which forms when an onshore wind blows over the cold coastal water. The low sea-surface temperature is caused by upwelling (*see* OCEAN AND OCEANOGRAPHY: *Movement of Sea Water*).

Surface Currents.—The surface currents of the Atlantic ocean primarily correspond to the system of prevailing winds with such modifications as are imposed upon the movement of the water by land boundaries. Other factors which influence the currents are regional excess of evaporation or precipitation, regional differences in cooling or heating, friction and the effect of the earth's rotation. In the North Atlantic the trade winds maintain a fairly steady current from east to west, partly by the direct action of the wind and partly by maintaining an accumulation of warm water on the northern side of the current. A great bulk of water carried by this current continues into the Caribbean sea and through the Strait of Yucatan into the Gulf of Mexico from which it flows out as a warm and swift current through the Straits of Florida. This current is re-enforced by water which has flowed on the eastern side of the Antilles and forms the Gulf stream off the American east coast. The Gulf stream follows the coast closely as far as Cape Hatteras, continues at some distance from the coast and turns more and more toward the east, flowing due east to the south of the Grand Banks of Newfoundland in latitude 40° N. In its further course the Gulf stream loses its identity as a well-defined current. The warm surface waters turn to the right and form part of the big eddy circulating around the Sargasso sea. Somewhat colder water continues toward the European coast as the North Atlantic current. One diffuse branch turns south and another branch turns north and splits up still more. One part, the Irminger current, turns northwest, washes the southeast coast of Iceland and continues past the southern cape of Greenland. The waters of this current become gradually mixed with cold low-salinity water from the Polar sea but the last traces of Gulf stream water are still found in latitude 65° N. off western Greenland. Another branch of the Gulf stream system enters the Norwegian sea to the north of Scotland. One small portion turns south into the North sea but the major part follows the coast of Norway to North cape and continues to Spitsbergen, sending minor branches into the Barents sea. North of Spitsbergen the current submerges below the less saline waters of the Arctic and continues as a subsurface current clear across the Polar sea where traces of Gulf stream water of temperature slightly above 0° C. are found to the north of the New Siberian Islands.

The surface layer of the Polar sea is throughout the year at a temperature close to freezing point (−1.6° C.) but is of relatively low density because the salinity has been reduced by runoff from the great Siberian rivers. This cold and low-salinity water flows

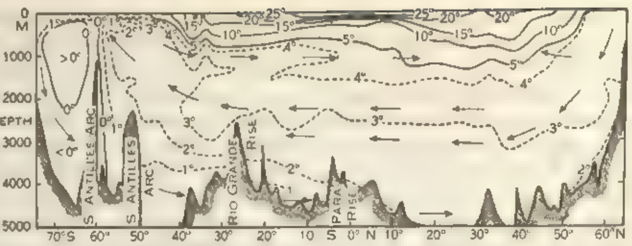
out from the Polar sea along the east coast of Greenland where it is gradually mixed with Atlantic water. It continues around the south cape of Greenland, Cape Farvel, flows north along the west coast of Greenland, turns around again and after addition of cold water from Baffin bay it flows south as the cold Labrador current. To the south of the Grand Banks of Newfoundland where this cold water meets the warm waters of the Gulf stream it is deflected toward the east and mixes with the Atlantic water. In winter this mixed water, which has a salinity of about 34.95 per mille (parts per thousand), is cooled to a temperature of nearly 3° C. whereby it attains a density high enough to make it sink to the bottom and spread to the south. On an average for the whole year, 5,230,000 cu.yd. of water sink every second (about 86 cu. mi. per day). Similarly, bottom water is formed in winter to the north of Iceland, but this has a considerably lower temperature, about −1° C. It fills the deep basin of the Norwegian sea but is prevented from flowing into the Atlantic ocean by the submarine ridge which extends from Scotland to Iceland and from Iceland to Greenland.

In the southeast part of the North Atlantic surface water flows in through the Strait of Gibraltar and high-salinity Mediterranean deep water flows out along the bottom of the strait and spreads over wide areas. Along the west coast of northwest Africa the Canary current flows to the southwest and continues across the southern part of the North Atlantic as part of the north equatorial current. Low temperatures prevail on the African coast, partly because the waters come from the north and partly because of upwelling.

The currents of the South Atlantic correspond in many respects to those of the North Atlantic. The southeast trade winds maintain the south equatorial current which flows toward the west where it divides into two branches, one that continues to the northern hemisphere and enters the Caribbean together with water from the north equatorial current, and one which turns south as a weak counterpart of the Gulf stream, the Brazil current. Between the equatorial currents the equatorial counter current flows toward the east and is particularly well developed off Ghana where it is known as the Guinea current. To the south of the high-pressure area of the South Atlantic the current flows to the east and turns toward the equator when reaching the African coast. There the Benguela current is more pronounced than its northern counterpart, the Canary current, and is characterized by lower temperatures near the coast, caused by more intense upwelling. Further south the Antarctic circumpolar current enters the Atlantic ocean through Drake passage, sending one branch, the Falkland current, a counterpart of the Labrador current, along the east coast of Argentina. The major branch of the Antarctic circumpolar current continues to the east into the Indian ocean, sending another branch to the south and feeding a large clockwise eddy in the Weddell sea.

The Deep-Sea Circulation of the Atlantic.—The deep and bottom water of the North Atlantic is, as already stated, formed by sinking of surface water between Iceland and Greenland and in the Labrador sea, from where it spreads to the south. At depths between 3,000 ft. and 6,500 ft. the water which flows out from the Mediterranean spreads and can be recognized by an intermediate salinity maximum. With increasing distance from the Mediterranean the salinity decreases because of mixing with other water masses, but traces of Mediterranean water are found as far south as latitude 40° S.

In the Antarctic, bottom water of temperature −0.6° C. and salinity 34.65 per mille is formed by sinking of water from the continental shelf. The temperature of this water is so low that its density is higher than that of the North Atlantic deep water. This water flows toward the north and can be traced as bottom water to 40° N. Surface water sinks at the Antarctic convergence in about latitude 50° S. and spreads to the north as low-salinity water. This Antarctic intermediate water also crosses the equator and can be traced to about 20° N. Large amounts of the Antarctic bottom water and intermediate water mix with the North Atlantic deep water, return to the south, and rise toward the surface between 50° and 60° S. lat. In rising the deep water brings quantities of



ADAPTED FROM SVERDRUP, JOHNSON, AND FLEMING, "THE OCEANS" (COPYRIGHT, 1942, PRENTICE-HALL)

FIG. 2.—VERTICAL SECTION SHOWING DISTRIBUTION OF TEMPERATURE IN THE WESTERN ATLANTIC OCEAN (AFTER WÜST)

plant nutrients, phosphates and nitrates to the surface layers, and the oceanic circulation therefore accounts for the high productivity of the Antarctic waters.

The deep and bottom waters of the Atlantic are characterized by a high oxygen content because there exists a fairly rapid circulation. The waters have sunk from the surface where they became saturated with oxygen by contact with the air.

Temperatures.—The distribution of the sea-surface temperature is closely related to the character of the currents. The waters of the north equatorial currents spread to the north and to the south when reaching the east coasts of North and South America and, correspondingly, the region of high-surface temperature is wide off the American east coasts but is narrow off the African coast where the Canary current and the Benguela current carry cold water toward the equator. Therefore, in latitudes about 10° S. to 30° S. and 10° N. to 30° N. the sea surface is warmer off the eastern coast than off the western, but poleward of 30° this feature is reversed. This reversal is barely evident in the South Atlantic where the Falkland current carries cold water up to about latitude 30° S. (in August to 25° S.) but is conspicuous in the North Atlantic. There the Labrador current brings cold water to latitude 40° N., whereas the extreme branches of the Gulf stream system carry warm water along the coast of Norway where ports remain ice-free even in latitude 71° N. The contrast between the South and the North Atlantic is related to the surface currents which in turn reflect the action of the prevailing winds and the effect of the shape of the coasts. Where the Falkland current meets the Brazil current and where the Labrador current meets the Gulf stream the surface temperature changes rapidly on a very short distance. The change is particularly striking when passing from the Gulf stream to the Labrador current ("the cold wall").

In the tropics the surface temperature is controlled by climatological factors to such an extent that it is nearly uniform, and differences related to currents do not appear. Such differences are very marked, however, at a depth of about 650 ft., where in latitude 6°–7° N. the temperature is 10° C. whereas it is 20° C. in latitude 20° N. The existence of the cold water at shallow depths to the north of the equator should not be interpreted as showing that deep water rises to the surface. The temperature distribution is directly related to the existence of equatorial currents which flow toward the west and within which the warm water must be to the right in the northern hemisphere and to the left in the southern.

The distribution of temperature at greater depths has already been touched upon when discussing the deep-water circulation. In the North Atlantic the temperature decreases slowly toward the bottom from a value of about 5° C. at 3,000 ft. to about 2.5° at the bottom. In the South Atlantic up to latitude 40° S. the temperature first decreases to a minimum between 3,000 ft. and 4,000 ft., increases again and reaches a maximum of 2°–4° C. at about 6,500 ft., indicating the flow of North Atlantic deep water, and then it decreases to less than 1° C. at the bottom where Antarctic bottom water is encountered. To the south of 40° S. low temperatures, 30° C. or less, prevail throughout, and near Antarctica a large body of water has a temperature below 0° C.

Salinity.—The surface waters of the North Atlantic ocean have a higher salinity than those of any other ocean, reaching values exceeding 37 per mille in latitudes 20°–30° N. The salinity

distribution is also related to the currents but is greatly influenced by evaporation and precipitation. Georg Wüst has shown that for each ocean the average surface salinity can be taken as equal to a constant basic value plus a correction which is directly proportional to the difference between evaporation and precipitation. The basic salinity value differs from one ocean to another and is highest for the North Atlantic. It is 35.5 per mille for the North Atlantic and 34.5 for the South Atlantic. This difference can be explained as the effect of the intense evaporation in the Mediterranean and the outflow from that sea of high-salinity water which maintains the salinity of the North Atlantic at a higher level than that characteristic of any other ocean. On an average for every latitude range, say 0° to 5° N., and so on, the deviations from the basic value are proportional to the difference between evaporation and precipitation. Near the equator precipitation dominates and surface salinities of about 35 per mille are encountered, but in latitudes 20° to 25° N. and about 20° S. evaporation greatly exceeds precipitation and over large areas the surface salinity is above 37 per mille. Proceeding poleward precipitation again becomes greater than evaporation and, correspondingly, the surface salinity decreases, in large areas to values below 34 per mille. Superimposed upon these general features are the effects of currents which again are more striking in the North Atlantic where Atlantic water of salinity exceeding 35 per mille is carried as far north as Spitsbergen in latitude 78° N. and Arctic water of salinity below 34 per mille is carried south to nearly 45° N. off Newfoundland. North of 40° N. the sea-surface isohalines run nearly in a north-south direction, whereas south of 45° S. they run east-west. In adjacent seas the salinity depends also upon the runoff from rivers. In the Mediterranean and the Red sea, where the runoff is small and evaporation is great, high salinities prevail; in the Black sea and in the Baltic where large rivers empty, the salinity is low. In the inner part of the Gulf of Bothnia between Sweden and Finland the water is nearly fresh. The surface water of the Polar sea has a salinity of 30–33 per mille because of admixture of fresh water from the great Siberian rivers.

Ice.—In winter the Polar sea is almost completely covered by sea ice which under the action of the wind has been broken and piled up in pressure ridges and hummocks. In summer, on the other hand, when the air temperature remains at about 0° C. from the end of June to the end of August, there are numerous patches of open water.

As much as 3 ft. of the ice melts during summer, but during the following winter new ice forms at the under side of the ice floes which by the end of the winter attain a thickness of about 10 ft. by freezing only. Where pressed together hummocks and pressure ridges rise to heights of 16 ft. or more above the general level and below these ridges the ice has a thickness of up to 65 ft.

It is probable that a great part of the pack ice of the Polar sea drifts with the winds in a clockwise eddy with its centre near the middle of the Polar sea. From this eddy a branch turns south along the east coast of Greenland and carries with it large masses of pack ice. The existence of the drift was first demonstrated by Fridtjof Nansen in 1893–96, and later by the drift of Russian vessels and of the Russian party which was landed by airplanes near the north pole in May 1937, and picked up off the east coast of Greenland in Feb. 1938. The icebergs of the North Atlantic come from the Greenland glaciers. In the Polar sea icebergs are encountered near Franz Josef Land (Fridtjof Nansen Land) and

FIG. 3.—VERTICAL SECTION SHOWING DISTRIBUTION OF SALINITY IN THE WESTERN ATLANTIC OCEAN (AFTER WÜST)

Spitsbergen, where small glaciers terminate in the sea. The ice islands, up to 18 mi. long and 200 ft. thick, apparently originate along northern Ellesmere Island and many have been sighted in the waters of the Canadian arctic archipelago. The icebergs from the glaciers on east Greenland are carried south by the east Greenland current, then north along the coast of west Greenland where many more are added, and finally south along the coast of Labrador. Off the Grand Banks of Newfoundland icebergs reach, in May and June, as far south as 42° to 43° N. where they seriously menace shipping. After the "Titanic" disaster in 1912 the international ice patrol was established by joint action of all nations with shipping interests in the North Atlantic. The ice patrol is conducted by the U.S. coast guard, which locates icebergs, predicts their drift and issues warnings. In winter the Labrador current also carries pack ice south.

Antarctica is surrounded by a belt of pack ice which in the Atlantic extends to about 55° S. at the end of the southern winter (October). At the end of the southern summer (March), the eastern and western coasts of the Weddell sea are often ice-free but the Weddell sea itself is covered by pack ice which drifts in a large clockwise gyral. Enormous icebergs break off from the Antarctic ice sheet and drift east and north. Flat-topped icebergs have been reported which have been up to 60 mi. long, 10 to 20 mi. wide and 300 ft. high. The average northern boundary of icebergs is in about 42° S., but on one occasion a small piece of floating ice was sighted in latitude 26° 30′ S., longitude 25° 40′ W.

ATLÁNTIDA, a small department, facing the Caribbean sea in northern Honduras. Area 1,641 sq mi.; pop. (1961) 92,832 Except for the southern portion, the department consists chiefly of fertile coastal and alluvial plains, where most of the population resides. Banana districts, located in the Atlántida plains and served by railways, produce 15% of Honduras' commercial bananas, which are mostly exported. The department ranks second in national production of yucca and sweet potatoes, third in bananas, fifth in rice, and is important in production of corn, beans, cattle and swine. La Ceiba, the departmental capital (pop. [1961] 24,868) and Tela are respectively fourth and third ports of Honduras and also the two chief cities of the department.

(C. F. J.)

ATLANTIS (ATALANTIS or ATLANTICA), a legendary island in the Atlantic ocean. Plato in the *Timaeus* describes how Egyptian priests, in conversation with Solon, represented the island as a country larger than Asia Minor with Libya, situated just beyond the Pillars of Hercules. Beyond it lay an archipelago of lesser islands. Atlantis had been a powerful kingdom 9,000 years before the birth of Solon, and its armies had overrun the Mediterranean lands, when Athens alone had resisted. Finally the sea overwhelmed Atlantis, and shoals marked the spot. In the *Critias* Plato adds a history of the ideal commonwealth of Atlantis. It is impossible to decide how far this legend is due to Plato's invention, and how far it is based on facts of which no record remains. Medieval writers, receiving the tale from Arabian geographers

believed it true, and had other traditions of islands in the western sea, the Greek Isles of the Blest, or Fortunate Islands; the Welsh Avalon (*q.v.*), the Portuguese Antilia (*q.v.*) or Isle of Seven Cities, and St. Brendan's Island, the subject of many sagas in many languages. All except Avalon were marked in maps of the 14th and 15th centuries and formed the object of voyages of discovery; conjecture as to the existence of St. Brendan's Island persisted until the 18th century. Somewhat similar legends are those of the island of the Phaeacians (Homer, *Odyssey*), the island of Brazil, of Lyonnesse (*q.v.*), the sunken land off the Cornish coast, of the lost Breton city of Is, and of Mayda or Asmaide, the French Isle Verte and Portuguese Ilha Verde or "Green Island." The last appears in many folk tales from Gibraltar to the Hebrides, and until 1853 was marked on English charts as a rock in 44° 48′ N. and 26° 10′ W. After the Renaissance attempts were made to rationalize the myth of Atlantis. It was identified with America, Scandinavia, the Canaries or Palestine. Ethnologists saw in its inhabitants ancestors of the Guanches, the Basques or the ancient Italians. Even in the 17th and 18th centuries the credibility of the legend was seriously debated, and sometimes admitted, even by Montaigne, Buffon and Voltaire.

ATLAS, in Greek mythology, son of the Titan Iapetus and Clymene (or Asia), brother of Prometheus. Homer, in the *Odyssey*, speaks of him as "one who knows the depths of the whole sea, and keeps the tall pillars which hold heaven and earth asunder." In the first instance he seems to have been a marine creation. The pillars that he supported were thought to rest in the sea, immediately beyond the most western horizon. But as the Greeks' knowledge of the west increased, the name of Atlas was transferred to a range in the northwest of Africa. Later, Atlas was represented as a king of that district, turned into a rocky mountain by Perseus, who, to punish him for his inhospitality, showed him the Gorgon's head (Ovid, *Metamorphoses*).

According to Hesiod (in the *Theogony*), Atlas was one of the Titans who took part in their war against Zeus, for which as a punishment he was condemned to hold aloft the heavens. In works of art he is represented as carrying the heavens or the celestial globe.

The plural form atlantes (*q.v.*) is the classical term in architecture for the male sculptured figures supporting a superstructure, as in the baths at Pompeii and in the temples at Agrigeno in Sicily. In 18th-century architecture half figures of men with strong muscular development were used to support balconies.

(T. V. B.)

ATLAS is a term commonly applied to a collection of maps or charts, usually bound together. Folio-form handbooks on technical subjects, such as groups of anatomical drawings or ethnographical plates and related tabular data, are sometimes called atlases, but the name is most widely used in connection with cartographic works. A figure of the Titan Atlas, holding a globe on his shoulders, was first used by Gerardus Mercator in the late 16th century and frequently by other map makers of the following centuries as a frontispiece for their collections of maps and charts. Gradually the name came to be applied to volumes of maps or charts and sometimes to nongeographical publications of similar format.

There is a great range in the quality, content and utility of atlases, but in addition to maps and charts they often contain pictures, tabular data, facts about areas and an index of place names keyed to co-ordinates of latitude and longitude, or to a locational grid with numbers and letters along adjacent sides of the maps.

Atlases may be classified fundamentally into world and regional works, with each of these categories subdivided into general reference atlases designed to aid in the location or identification of geographical features or political entities, and special subject atlases providing detailed information about the boundaries, climate, economy, geology, history, languages, population, religions, resources, telecommunications, vegetation and other characteristics of an area.

Although the rediscovery of Ptolemy's *Geographia* in the 15th century, with the addition of *Tabulae Modernae* listing new place names and spellings, aroused interest in map making, collections of maps bound together in atlas form appear to have originated with the *Theatrum orbis terrarum* of A. Ortelius in 1570. Another monument of 16th-century cartography is the *Lafréri Atlas* containing maps compiled by gifted Italian cartographers between 1556 and 1575. In the following century fine atlases were prepared by V. Coronelli and other Italian cartographers, but in the production of high-grade maps the Dutch were supreme, as is illustrated by the classic atlases of Mercator, W. J. and J. Blaeu, H. Hondius, J. Jansson and N. Visscher. French atlases by N. Sanson and N. de Fer in the 17th century and by G. Delisle, C. H. Jaillot and G. L. LeRouge in the 18th were less ornate but equal in accuracy and richness of content to the Dutch and Italian maps. Contemporary German atlases such as those by the House of Homann, were burdened with enormous detail, numerous insets, notes and pictures. English atlases of the period resembled the Dutch in style but appeared more crowded. Among the more famous are works by C. Saxton in the 16th century, J. Seller, J. Speed and J. Ogilvie in the 17th century and J. Senex, William Faden, T. Jefferys and T. Kitchin in the 18th.

Among the most widely used great world atlases of modern times, indexing 250,000 to 500,000 place names, are Andree's *Allgemeiner Handatlas* (1881–1930); Stieler's *Handatlas* (1816–1937); the *Atlante Internazionale* of the Italian Touring club (first published 1929); the Soviet atlas *Mira* (first published 1954); and the London Times *Atlas of the World* in five volumes (1955–59). Detailed national atlases have been published in the 20th century by more than 35 countries. That of Canada approaches the ideal in organization, content and cartographic presentation. Regional and local atlases can show greater detail, and plans such as those of the Sanborn atlases of cities in the United States show even the structure and use of buildings.

The *Encyclopædia Britannica World Atlas* presents a world coverage of maps, statistical tables and an index of locations by name. The atlas, divided into five parts—political-physical maps, "The World Scene," "Geographical Summaries," "Geographical Comparisons" and an index—illustrates, for example, world distribution of crops, population, industry, political geography and physical features. The statistical section, "Geographical Summaries," includes data for over 200 countries on political subdivisions, population, productive enterprises, trade, finance, transportation, communications, education and health. "Geographical Comparisons" lists natural and man-made physical features of the world.

ATLAS MOUNTAINS, the name for the mountain chains more or less parallel to the coast of northwest Africa. The name was given by Europeans who supposed them to be the home of the mythical Greek god, and is never used by the native races.

Geology.—The Atlas mountains form part of the Tertiary Alpine-Himalayan fold system. In them, rocks of all types and ranging from Pre-Cambrian to Miocene are intensely folded and often highly metamorphosed, the fold pattern being similar to that throughout the whole Alpine system. The movement commenced there at the end of the Jurassic, was renewed in the Upper Cretaceous and continued into the Miocene. There is also evidence of folding during earlier periods (Variscan in the Moroccan Meseta). The trend of the folds is approximately east-west, the folds having moved southward over the Saharan-African hinterland. The trend is continued eastward through Sicily into the Apennines, and westward into the Canary Islands. Intense glaciation occurred during the Ice Age as shown by moraines, etc., and some peaks are still snow-capped.

Sub-Divisions.—The Atlas mountains extend 1,500 mi. from southwest Morocco to northern Tunisia, traversing Morocco, Algeria and Tunisia. They form a topographic and climatic barrier between the Mediterranean sea to the north and the Sahara desert

to the south. They can be divided into two main chains: (1) the Maritime Atlas from Ceuta to Cape Bon; and (2) the inner and more elevated ranges, which, from Cape Guir, run south of the coastal ranges. The western inner ranges (the Moroccan ranges) are the most impressive of the whole system. The Maritime Atlas and the inner ranges in Algeria and Tunisia are treated under *The Eastern Ranges* below.

The Moroccan Ranges.—This section, whose Berber name is Idráren Dráren, consists of five ranges more or less parallel to one another and with a trend from southwest to northeast.

1. The main range, the High or Great Atlas, has a central position and is the longest and loftiest chain, with an average height of more than 11,000 ft. The slopes are precipitous toward the Atlantic but gradual toward the Dahra district (west of Algiers). Several summits are snow-clad during most of the year. The northern sides and tops of the lower peaks are often covered with forests of cork, oak, pine, cedar and other trees, with walnuts up to the limit of irrigation. Their lower slopes enclose well-watered valleys in which the Berber tribes cultivate tiny irrigated fields, their houses clinging to the hillsides. The southern flanks, being exposed to the hot dry winds of the Sahara, are generally destitute of vegetation.

The crest of the range has been deeply eroded, forming devious passes. The central section, culminating in Toubkal, 13,665 ft., maintains a mean altitude of 11,600 ft., and from this great mass a number of secondary ridges radiate. The best-known passes are: the Bíbáwan in the upper Sous basin (4,882 ft.); the Tizi n' Test, giving access from Marrákech to Tároudánt, rugged and difficult, but low; the Tizi n' Tichka (7,438 ft.) and the Talghemt (7,250 ft.), leading to Tafilált. There are two passes accessible to normal traffic which afford communication between the Tensift and Sous basins.

2. The lower portion of the Moroccan Atlas (the Middle or Moyen Atlas) north of the High Atlas, is crossed by the pass from Fès to Tafilált, both slopes being wooded. From the north this range presents a regular series of snowy crests.

3. The Anti-Atlas (Djebel Sarro or Lesser Atlas) runs parallel to and south of the central range and has a mean altitude of 5,000 ft., although some peaks and even passes exceed 6,000 ft.

4. The Djebel Bani, south of the Anti-Atlas, is a low, narrow rocky ridge with a height of 3,000 ft. in its central parts.

5. The foothills of Ghaiáta, north of the Middle Atlas are a series of broken mountain masses from 3,000 to 3,500 ft. high, to the south of Fès, Táza and Tlemcen. The last two are parallel ranges of less importance.

The Eastern Ranges.—The lesser range (Maritime Atlas also known as the Little Atlas, Tell Atlas or Atlas Tellien) nearer the sea, is not so impressive. From Ceuta to Melilla (150 mi.) the Rif mountains face the Mediterranean, and there, as along the whole coast eastward to Cape Bon, many rugged rocks rise boldly above the general level. In Algeria the Maritime Atlas has five chief ranges, several mountains exceeding 5,000 ft. The Djurdjura range, extending through Kabylia from Algiers to Bougie, contains Lella Khedidja (7,572 ft.) and Djebel Adrar (6,542 ft.). The Medjerda range, which extends into Tunisia, has no heights exceeding 3,947 ft. It was in these coastal mountains that the Romans quarried the celebrated Numidian marbles.

The southern or main range of the eastern division, the Saharan Atlas (Atlas Saharien), is linked by secondary ranges to the mountains of Morocco. The Saharan Atlas is essentially one chain, though known under different names: Ksour mountains (west), Djebel Amour, the Ouled-Naïl, and the Aurès (east).

The central part, the Zab mountains, is of lower elevation, the Saharan Atlas reaching its culminating point, Djebel Chélia (7,648 ft.), in the Aurès. This range sends a branch northward which joins the Medjerda range of the Maritime Atlas, and another branch runs south by Gafsa to the Gulf of Gabès. There Mt. Sidi Ali bu Musin reaches a height of 5,066 ft., the highest point in Tunisia. In the Saharan Atlas the passes leading to or from the desert are numerous, and in most instances easy.

Both in the east (at Batna) and the west (at Aïn-Sefra) the mountains are traversed by railways, which, starting from Mediterranean seaports, take the traveler into the northern [illegible] the Sahara.

History and Exploration.—The Atlas are the home of [illegible] races, and those in the least accessible regions have been [illegible] ent throughout their recorded history. In general the M[illegible] range was well known to the Romans, but some mountain [illegible] of Kabylia had never been visited by Europeans until the [illegible] military expedition of 1857. The Djebel Amour was travers[ed by] the column which seized Al Aghuat in 1852, and the survey [of the] mountains dates from that time.

The ancient caravan route from Mauritania to the western [illegible] crossed the lower Moroccan Atlas via the pass of Talghem[t] [illegible] through the oasis of Tafilált (*q.v.*), formerly known as [illegible] on the east side of the Anti-Atlas. The Moroccan system [was] visited and in some instances crossed, by various European [trav]elers carried into slavery by the Salli rovers, and was travers[ed] by René Auguste Caillié (*q.v.*) in 1828 on his journey [illegible] Tombouctou, but the first detailed exploration was made [by] Friedrich Gerhard Rohlfs in 1861–62.

In 1871 the first scientific expedition, consisting of [illegible] Hooker (afterward Sir), John Ball and G. Maw, explored [the] central part of the High Atlas. They ascended by the Ait M[illegible] valley to the Tagharat pass (11,484 ft.) and by the Amsmiz [illegible] to the summit of Djebel Tezah (11,972 ft.). Oskar Lenz in 18[illegible] 80 surveyed a part of the High Atlas north of Tároudánt det[er]mined a pass south of Iligh in the Anti-Atlas, and penetra[ted] thence across the Sahara to Tombouctou. He was followed [in] 1883–84 by Vicomte Charles de Foucauld, whose itinerar[ies in]cluded parts of the first and middle ranges; three routes over the High Atlas; and six journeys across the Anti-Atlas, with a gene[ral] survey of the foot of this range and several passages over [the] Djebel Bani. Then Joseph Thomson explored some of the [cen]tral parts in 1888; and Walter B. Harris explored some [of the] southern slopes and crossed the Atlas at two points during h[is ex]pedition to Tafilált in 1894. In 1901 and again in 1905 the m[arquis] de Segonzac, a Frenchman, made extensive journeys in the Mo[roc]can ranges. A member of his expeditions, De Flotte Rocquev[aire] made a triangulation of part of the western portion of the m[iddle] Atlas.

Since that time numerous travelers and scientists have [illegible] and explored the mountain (*see* also MOROCCO; ALGERIA, T[UNISIA] and SAHARA).

Minerals.—The mountains have considerable mineral potent[ial]. The development of better transport facilities will permit [the] exploitation of the reserves. Extensive exploration for na[tural] oil is going on throughout the Atlas region and also farther [illegible] in northern Sahara. Intensive work is now concentrated [in the] following four zones in the Maritime Atlas of northern Alger[ia]: (1) Oued Gueterini (Sidi-Aïssa); (2) South Tellian, (3) H[illegible] basin; and (4) Est-Constantinois basin. In the first region [illegible] quantities of oil are being produced and oil and or gas ha[ve been] proved in all the others. The oil is transported by pipeline [from] the oil fields to the Mediterranean ports of Algeria. Coal is m[ined] in Morocco and mineral phosphates abound in several [illegible] farther east. Other mineral resources are iron, manganese [illegible] zinc and antimony. (J. I. P.)

ATMOSPHERE. An atmosphere is the gaseous enve[lope] which covers a planet or large satellite (Gr. *atmos*, "vapour" [and] *sphaira*, "sphere").

The ocean of air in which we move and have our being [illegible] flows around us and sustains life on earth, owes its unique [illegible] benevolent character to a superb balance among the forces [of na]ture. Every planet in the solar system possesses an atmosphere, with the possible exception of the scorched little planet Mer[cury] circling closest to the sun. Several of the satellites of the [illegible] planets are also large enough to possess atmospheres. However, life as we know it is impossible on any of these other bodies.

To understand that balance of natural forces which determine[s] the atmosphere a body in space will have, the astronomer and [the] physicist must work together, the one probing the planets [with] his telescopes and radio antennas, the other examining the [illegible] of the planet Earth. From these efforts is gradually emerging [illegible]

understanding of how the planets came to be.

PLANETARY ATMOSPHERES

Before the planets were formed there existed a cloud of gas and dust, a mixture of all the elements contained in the solar system. In this mixture hydrogen and helium, the lightest gases, were by far the most plentiful and the heaviest elements were in general the least plentiful. As the gas condensed and the planets grew out of the gas and dust mixture the solid portion of each planet became the nucleus, or central part, and the gases and liquids clung to the surface. However, the gases were constantly in motion, due to the heat of the nucleus and of the sun, and some molecules gained enough velocity to escape from their parent body forever.

The amount of gas which a body in space can permanently retain around itself is determined by a long-term balance between its gravitational attraction, which holds the gas and prevents it from flying off into space, and the temperature of the gas at the top of the atmosphere, which is a measure of the energy available to the gas to escape. For example, the moon's mass is about one-eightieth that of the earth. Since it has a small gravitational attraction, and since the temperature is sufficiently high on the sunlit side, all but the very heavy gas molecules have gradually escaped. Earth, Venus and Mars are able to retain appreciable atmospheres, but lighter gases such as hydrogen and helium slowly escape even from these planets.

The large outer planets, Jupiter, Saturn, Uranus and Neptune are sufficiently cold due to their great distance from the sun, and sufficiently massive to retain large amounts of hydrogen and helium. In fact, these two elements are the most abundant ones in the atmospheres of these giant planets. Furthermore, their atmospheres are very thick, although just how thick is not known, since astronomers cannot probe beneath their swirling vapours of ammonia and methane.

The atmospheres of Venus, Earth and Mars are dissimilar in many respects. Nitrogen is probably the predominant gas in all three, and all contain carbon dioxide. Here the similarity ends. In the Venusian atmosphere methane and ammonia have been identified in amounts that are large in comparison to Earth. Free molecular oxygen is known to exist only in the earth's atmosphere.

Surface pressures of the three atmospheres differ also. The surface pressure is a measure of the total mass of the atmosphere from the surface of the planet to the top of the atmosphere (*see* below). On Earth the average surface pressure is about 1,015 millibars (mb.) (1 mb. = 1,000 dynes per square centimetres) or about 15 lb. per square inch. On Mars it is estimated to be between 50 and 100 mb. (corresponding to the pressure at 50,000 to 65,000 ft. in the terrestrial atmosphere). On Venus it is about 160 mb. at the top of the impenetrable clouds which cover the planet. The surface pressure on Venus is greater than this, but how much greater is not known.

Since an atmosphere forms a gaseous barrier between the surface of a planet and outer space, planetary atmospheres have important effects on surface conditions. They absorb the ultraviolet rays from the sun. They are sufficiently thick, except on Mercury and probably Pluto, to prevent all but the larger meteoroids from hitting the surface. They are constantly in motion, due to the application of solar heat and the planets' rotation. This motion erodes the solid surface and slowly levels mountains. Finally, in the case of Earth, the atmosphere supports animal and plant life.

THE TERRESTRIAL ATMOSPHERE

History.—The ever-changing sky has always inspired and intrigued mankind. Depending on the good graces of the weather for so many of his pursuits, man recognized early the necessity of studying the weather. The farmer watched the sunset and the motions of the clouds to determine if the next day would bring rain; the mariner watched the same signs, and as ships ranged around the world mariners prepared charts which showed the belts of the trade winds and the patterns of the monsoons (*see* also METEOROLOGY; WEATHER FORECASTING).

At the close of the 19th century, man began seriously to probe the upper atmosphere. However, with kites and manned balloons, he was able to reach heights of only a few thousand feet. In 1904, L. P. Teisserenc de Bort in France published the results of 581 free balloon ascents, in which recoverable, lightweight instruments measured the temperatures and pressures in the atmosphere to a height of about 14 km. (45,000 ft.).

The decades that followed these first balloon ascents saw rapid advances in knowledge of the upper atmosphere. Improved balloons, some transmitting their instrument records by radio, reached heights of over 40 km. (130,000 ft.). Higher regions were explored by a variety of means. Studies were made of the behaviour of sound waves from explosions, since these waves were observed to be refracted downward by the warmer strata aloft. The heights at which meteors appeared and disappeared gave indications of the density of the air between about 100 and 50 km. (330,000 to 160,000 ft.), and the occasional long-enduring luminous trail left by a meteor in the sky gave an indication of the winds in this region. The way in which the rays of the setting sun were scattered in the upper reaches of the atmosphere revealed information regarding the density of the air and the amount of suspended dust aloft.

In 1913, C. Fabry and M. Buisson reported the existence of ozone, a gas created by a photochemical reaction between sunlight and oxygen. Ozone provided an explanation for the warm region that, in the 1920s, was discovered to exist at about 50 km. (160,000 ft.). The behaviour of the ozone in the upper air, its distribution, the way in which it moves with the seasons, were subjects which in the second half of the 20th century constituted important facets in the study of the upper air.

A particularly powerful tool in early upper atmosphere research was the radio wave. The region above about 100 km. (330,000 ft.), known as the ionosphere, is electrically conducting and absorbs and reflects radio waves that have frequencies below about 10 mc. per second. This was understood as early as 1901, when A. E. Kennelly in the U.S. and O. Heaviside in England almost simultaneously predicted the effect of the ionosphere on radio waves. However, it was not until 1925, in both England and the U.S., that radio wave techniques were successfully used for the specific purpose of measuring ionospheric properties.

The electrical properties of the ionosphere, combined with the air motions in these regions, cause electrical currents to flow in a complex pattern. These high altitude electric currents cause changes in the earth's magnetic field (*see* also GEOMAGNETISM). In fact, the first suggestion of the existence of an electrically conducting layer in the atmosphere was made by Balfour Stewart in 1878, who based his conclusions on geomagnetic observations.

By 1946, when the first V-2 rocket devoted to exploring the upper atmosphere was fired from the White Sands proving ground, N.M., the major facts concerning the upper atmosphere had been fairly well established. The general features of temperature distribution, composition and density had been determined from the remarkable set of indirect observations and deductions just described. Further information had been provided by theoretical reasoning. However, the series of rocket observations which started in 1946 not only described the atmosphere itself more precisely than before, but they also provided invaluable information about the solar radiation which is absorbed in the upper atmosphere. Solar radiation in the ultraviolet and X-ray (very short wave) region of the spectrum has an important effect on the atmosphere, particularly the upper part. The scientific satellite program in connection with the International Geophysical year (1957–58), which was in a sense an extension of the sounding rocket program, is particularly useful in this respect, since satellites can observe the sun continuously.

Atmospheric Nomenclature.—The earth's atmosphere has a number of regions, one above the other, each with a unique set of characteristics. Though the boundaries between these regions are not always distinct, it is convenient to distinguish among them and to assign a name to each.

The part of the atmosphere in which we live, in which most clouds form and which is the theatre for weather as we know it, is called the troposphere. In the troposphere temperatures decrease with height, on the average, and there is a considerable amount of turbulent mixing. Most of the water vapour is trapped in this

TABLE I.—*Composition of the Lower Atmosphere*
(*Permanent Constituents*)

Constituent	Formula	Volume %
Nitrogen	N_2	78.084 ± .004
Oxygen	O_2	20.946 ± .002
Argon	Ar	0.934 ± .001
Carbon dioxide	CO_2	0.033 ± .001*
Neon	Ne	18.18 $\times 10^{-4}$
Helium	He	5.24 $\times 10^{-4}$
Krypton	Kr	1.14 $\times 10^{-4}$
Xenon	Xe	0.087 $\times 10^{-4}$
Hydrogen	H_2	0.5 $\times 10^{-4}$
Methane	CH_4	2.0 $\times 10^{-4}$
Nitrous oxide	N_2O	0.5 $\times 10^{-4}$

*Estimates of the rate of increase of carbon dioxide in the atmosphere due to the rapid burning of the earth's reserves of organic fossil fuels range from 2% to 3% of this value per decade, though the data are not entirely conclusive. There is considerable local variation of CO_2 due to localized sources and sinks. Ref.: E. Glueckauf.

region. The upper boundary of the troposphere is the tropopause, and it is often quite abrupt. The height of the tropopause varies from about 8 to 12 km. (25,000 to 40,000 ft.) at high and middle latitudes, and from about 16 to 18 km. (50,000 to 59,000 ft.) over the equator.

Immediately above the tropopause is a nearly isothermal (constant temperature) region followed by a region of temperature increase called the stratosphere (*q.v.*). For some time after the early observations of De Bort, whose balloons penetrated into the stratosphere, it was thought that the isothermal region might extend upward indefinitely, and so in much of the early literature the word stratosphere was used loosely to refer to everything between the troposphere and the ionosphere. This definition is still used by some, even though it is recognized that the isothermal region does not extend very far, and it is generally absent in the tropics.

The region between the stratosphere and the ionosphere is called the mesosphere, a term introduced by Sidney Chapman in 1950. In the mesosphere temperatures decrease with height to about 80 km. (250,000 ft.).

Above this is the ionosphere (*q.v.*), where the temperature increases with elevation, reaching very high values at the upper fringes of the atmosphere (*see* Table II). It is a region in which the short-wave radiation of the sun has a dominant effect. The bombardment by powerful short-wave radiation causes certain molecular constituents of the air to dissociate into their atomic form, and also to become ionized by the release of free electrons. The presence of large numbers of charged ions and free electrons above 100 km. (330,000 ft.) causes this part of the atmosphere to be a relatively good electrical conductor. At a sufficiently high level in the ionosphere an atom or molecule moving vertically upward would have a small but finite chance of escaping completely from the atmosphere without collision with an air particle. In other words, above this level some air particles will be able to travel in free orbits out of the atmosphere and back again. Lyman Spitzer, who studied this region theoretically (1949), used the word exosphere, a term which has gained general acceptance.

Atmospheric Composition.—The atmosphere in the troposphere is made up of a mixture of gases which, with the exception of a few constituents to be discussed, is quite constant. The percentages by volume of each of the permanent or relatively nonvariable gases in the lower atmosphere are summarized in Table I. In addition to these relatively permanent gases there are some constituents in the atmosphere which undergo changes of state or chemical reactions. In the troposphere water vapour, which enters the atmosphere by evaporation from the surface, leaves the atmosphere as rain, snow, hail, dew or frost (*see* HUMIDITY, ATMOSPHERIC). The amount of water vapour at sea level may vary from 20 g. or more per kilogram of air in the tropics to less than 0.5 g. per kilogram of air in cold, dry polar continental air masses. In addition, as G. M. B. Dobson, A. W. Brewer and R. J. Murgatroyd in England and C. J. Brasefield in the United States have shown by a number of ascents with aircraft and balloons, the distribution of water vapour is extremely variable in the vertical. It appears that vertical mixing proceeds at such a slow rate that layers of water vapour can persist for periods of several days to several weeks. These observations show that regardless of season there is a marked decrease in the water vapour above the tropopause, verifying the expectation that the upper atmosphere is much drier than the troposphere.

The other important variable in the atmospheric composition is ozone. Ozone is formed by photochemical processes in the mesosphere. Solar ultraviolet radiation causes the dissociation of molecular oxygen, and the atomic oxygen then combines with the remaining oxygen to form triatomic ozone. This results in a maximum concentration at about 20 to 30 km., but even here only a few parts of ozone are present per 1,000,000 parts of air.

If all the ozone present in a vertical column that extended through the entire atmosphere were collected at sea level in a container of the same cross section as the column, the thickness of the pure ozone sample would be between 0.2 and 0.4 cm. (This is the usual way of expressing the total ozone content of the air.) The total ozone content at middle latitudes is at a maximum in the spring and at a minimum in the fall. It may be nearly 0.4 cm. at high latitudes and less than 0.2 cm. near the equator. There is a build-up of ozone in polar regions in winter as the air in the mesosphere converges toward the poles, bringing ozone from lower latitudes. In the spring the flow is reversed, and there is an increase in total ozone at middle latitudes.

The heavier gases in the atmosphere have a tendency to settle down into the lower layers, while the lighter gases such as hydrogen and helium tend to gravitate to the top of the atmosphere. These tendencies are counteracted by the continual stirring of the atmosphere, which, over a long period of time, is apparently so effective that even up to altitudes of 70 km. (230,000 ft.), where rockets have obtained air samples, the separation of the heavier from the lighter elements is barely detectable. At higher altitudes in the ionosphere it is probably quite marked.

Temperature, Pressure and Density Distribution.—The atmospheric pressure at the surface of a planet is the result of gravity pulling down on the entire atmosphere. Surface pressure is a measure of the weight of an atmosphere above a surface, and as one moves upward the pressure decreases because there is less air above. The change of pressure, Δp, for a given change of height, Δh, is given by the hydrostatic equation:

$$\Delta p = -g\rho\Delta h$$

where g is the acceleration of gravity, and ρ is the average air density in the height interval. The density is a function of the pressure, and of the temperature and molecular weight of the air. This relationship is given by the equation of state:

$$\rho = \frac{pM}{RT}$$

where M is the molecular weight, T is absolute temperature (in degrees Kelvin), and R is a physical constant known as the universal gas constant (8.314×10^7 ergs per mole-degree). Substituting for ρ in the hydrostatic equation:

$$\frac{\Delta p}{p} = -\frac{Mg}{RT}\Delta h$$

This fundamental equation allows one to calculate pressure throughout an atmosphere if the temperature and molecular weight are known, or to calculate temperature if pressure and molecular weight can be measured.

TABLE II.—*Standard Atmosphere*

Altitude		Absolute temperature		Molecular weight	Pressure	
km.	ft.	°K. (Kelvin)	°R. (Rankine)		mb. (millibar)	lb.-force sq ft

*Top of 1952 ICAO Standard Atmosphere.
†Top of 1956 United States Extension to the Standard Atmosphere.

Although there are complex variations in temperature and pressure with time and space, it has been found convenient to establish an average vertical distribution to use as a reference for aeronautical and other purposes. Table II is a condensation of the 1952 International Civil Aviation Organization (ICAO) Standard Atmosphere, which has been adopted as an international standard up to 20 km. (65,820 ft.), and above this of the 1956 U.S. Extension to the Standard Atmosphere. Values have generally been rounded off to four significant figures below 100 km. (330,000 ft.) and to three significant figures above this (except for molecular weight). Intermediate values of temperature in the Standard Atmosphere can be obtained approximately by interpolating linearly with altitude. Intermediate values of pressure or density must be obtained by integrating the hydrostatic equation, using the proper temperature-height distribution. Such an integration above 91.29 km. is further complicated by the changing molecular weight, and at great altitudes the change of gravity with height becomes significant also. However, for most purposes the pressure and density can be interpolated with satisfactory accuracy by plotting the logarithm of the values given against height, and connecting these points with straight lines.

Standard sea level values for the atmospheric properties in metric and British units are as follows:

Temperature:	288.16° K. = 518.688° R. = 15° C. = 59° F.
Pressure:	1,013.25 mb. = 760.00 mm. of mercury = 29.921 in. of mercury = 2,116.22 lb. per square foot = 14.696 lb. per square inch.
Density:	1.2250 kg. per cubic metre = 0.002378 slugs per cubic foot.

Note that the temperature in degrees centigrade and Fahrenheit, and the pressure expressed in millimetres of mercury (*see* METEOROLOGY) are exact by definition; all the other quantities are derived.

ATOLL, a horseshoe or ring-shaped reef of coral enclosing a lagoon. Its form may be likened to that of a partly submerged dish with pieces broken from its edge. The dish is formed of hard coral and the shells of various reef-dwelling mollusks covered, especially at the seaward periphery, with a film of living coral polyps that continually extend the fringe and enlarge the diameter of the atoll. The lagoon entrance in the open part of the horseshoe is always to leeward of prevailing winds. Atolls are found only in waters shallow and warm enough to support coral life. The great area of atoll formation is the central, western and southwestern Pacific.

See CORAL REEF.

ATOM. The word atom, from the Greek *atomos* ("indivisible"), can be said to define the ultimate unit of something whose structure is granular or discontinuous. In particular, it is applied to the smallest amount of a chemical element ever found to take part in a chemical reaction. This definition of the atom in chemical terms does not imply that further subdivision, by processes other than chemical, may not take place. Indeed, the subdivision of atoms by a variety of physical means has become commonplace. Because, however, the subdivision of an atom destroys its original chemical identity, and because man's everyday experience of matter depends largely on its chemical composition and properties, the concept of the chemical atom as an ultimate building block is a useful and durable one.

This article traces the development of that concept, and then considers the structure and properties of individual atoms, in accordance with the following outline:

I. THE BEGINNINGS OF ATOMIC THEORY

The earliest well-authenticated expressions of the view that the ultimate structure of matter is discrete, rather than continuous, are ascribed to Democritus (*q.v.*), who lived about 420 B.C. It may well be that precedence should be given to Leucippus, who is said to have lived about 450 B.C. and who is quoted by Aristotle; however, Leucippus' existence was denied by Epicurus (341–270 B.C.). According to Democritus, "The only existing things are the atoms and empty space; all else is mere opinion." From this standpoint, qualities such as colour, taste, smell and texture were secondary, not basic; they could not be associated with the individual atoms, which were to be described solely in terms of geometry and motion. If, in fact, atoms had to be invested with all the properties of bulk matter, an atomic theory would not contribute in the slightest to man's understanding of nature. (If a person observes that a certain gas is green, and says that this is because its atoms are green, he has not offered an explanation of any consequence.) In this respect the approach taken by Democritus, though entirely speculative, contained a recognition of what a scientific explanation entails. He limited the properties of atoms to position, size, shape and motion, and believed that all the secondary properties of material things would thereby follow. His atoms were in ceaseless motion, infinitely numerous, and indestructible; his universe was strictly materialistic.

Much the same type of primitive atomic theory was espoused by Epicurus, whose views were eloquently transmitted to posterity by Lucretius in his poem *De rerum natura*. Here are found the assertions that nothing is ever annihilated, that matter is composed

of invisible atoms, that the atoms are always on the move, and that they are themselves devoid of colour, heat, sound, taste and smell. The properties of objects are due to varieties in the size and shape of atoms. The number of atomic shapes is large though finite, but the number of atoms of any one shape is infinite.

The atomism of the ancient Greeks was echoed many centuries later by such men as Giordano Bruno (1548–1600), Francis Bacon (1561–1626), Descartes (1596–1650) and Sir Isaac Newton (1642–1727). The main emphasis was still, however, more philosophical than scientific. Thus, for example, Newton: "It seems probable to me that God in the beginning formed matter in solid, massy, hard, impenetrable movable particles, of such sizes and figures, and in such proportion to space, as most conduced to the end for which He formed them. . . . And . . . that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations and motions of these permanent particles. . . ."

It was Daniel Bernoulli (1700–1782) who, in his book *Hydrodynamica* (1738), extracted for the first time a quantitative physical result from the picture of the chaotic motions of atoms. He showed that, if a gas is composed of swiftly moving atoms whose diameters are small compared to their separations, the pressure of a confined sample of the gas will be inversely proportional to its volume. This result was in accord with experiment (as expressed in Boyle's law) and marked the birth of a rational kinetic theory of gases (*see* KINETIC THEORY OF MATTER). It remained, however, for the growth of a quantitative science of chemistry (*q.v.*) to place the atomic theory on a solid experimental foundation.

II. DALTON'S THEORY

The rise of chemistry in the late 18th and early 19th centuries disclosed certain underlying features which the English chemist and physicist John Dalton was able to explain through a detailed atomic theory. First among these was the discovery of chemical elements, defined as those substances that cannot be further resolved into other substances by any means (*see* ELEMENTS, CHEMICAL). This concept of element had been clearly stated in 1661 by Robert Boyle in his book *The Sceptical Chemist*, and by 1800 about 25 or 30 substances conforming to the definition had been recognized. The second important discovery was expressed in the law of conservation of mass in chemical reactions. This result—carefully confirmed, though not originated, by A. L. Lavoisier (1743–1794)—lent powerful support to the original atomistic idea that all chemical changes are simply the reorganization of unchanging fundamental units. The third, and perhaps most crucial, discovery was expressed in the law of definite proportions (J. L. Proust, 1799), which states that every pure chemical compound contains fixed and constant proportions (by weight) of its constituent elements. Whenever a pure substance (composed, for example, of two elements) is broken down into those elements, they appear always in the same proportions. If the compound substance is synthesized by causing the two elements to react with each other, a surplus of one element or the other will be left over unless their amounts have been chosen to correspond to the proportions required.

1. Postulates.—Dalton was able to justify all these results with the postulates of his atomic theory, the main features of which were the following:

1. Matter consists of indivisible atoms.
2. All the atoms of a given element are identical in weight and in every other property.
3. Different elements have different kinds of atoms. In particular, the atoms of different elements are different in weight.
4. Atoms are indestructible, and chemical reactions are merely a rearrangement of atoms.
5. The formation of a compound from its elements takes place through the formation of "compound atoms" containing a definite (and small) number of atoms of each element.

These postulates were given final expression in Dalton's *A New System of Chemical Philosophy*, the first volume of which was published in 1808.

2. Rule of Greatest Simplicity.—The importance of Dalton's theory resided not so much in its novelty (much of it was indeed old) as in its concreteness. It made a clear and definite statement of the assumptions, and in particular laid great stress on the weights of atoms. The theory was thereby brought firmly to a point where it would stand or fall by the quantitative test of its predictions. In furtherance of this end, Dalton added another principle which, although later history showed it to be invalid contributed largely to the success of the theory. This was the "rule of greatest simplicity"; it asserted that if two elements formed only one known compound, that compound represented the union of one atom of each element. Its significance was that it permitted conclusions to be drawn about the relative weights of the atoms themselves. Thus, for example, in Dalton's day the only known compound of oxygen and hydrogen was water, formed by the reaction of about eight parts by weight of oxygen with one part by weight of hydrogen. (Dalton quoted a ratio of 7 to 1 instead of 8 to 1, but this was the result of inaccurate analysis.) The rule of greatest simplicity would specify the formula HO for water, and would lead to the conclusion that an atom of oxygen (O) weighs eight times as much as an atom of hydrogen (H). The fact that in this particular instance the numerical result is wrong (because the correct formula for water is H_2O) should not prevent a recognition of the perspicacity of Dalton's approach.

3. Law of Multiple Proportions.—Through a natural extension of the rule of greatest simplicity, Dalton supplied one of the most powerful arguments for his theory. The extension was merely this: if the atoms of two different elements are denoted by A and B, their combinations (assuming more than one to be possible) are likely to take such simple forms as A + B, A + 2B, 2A + B, A + 3B, etc. To make a compound corresponding to the combination A + 2B (or AB_2) will, for a fixed amount of element A, require exactly twice as much of element B as is needed to make the combination A + B (or AB). And although experimental data on the various compounds were already available in Dalton's time, the data had never before been analyzed from this point of view. It was known, for example, that carbon and oxygen formed two distinct compounds; one of them contained 28% by weight of carbon and 72% by weight of oxygen, the other contained 44% carbon and 56% oxygen. These figures take on a new significance if the ratio of oxygen to carbon is computed from them in each case:

	% Carbon	% Oxygen	% Oxygen / % Carbon
first compound	28	72	2.57
second compound	44	56	1.27

It is seen that the ratio of oxygen to carbon is almost exactly twice as great in the first compound as in the second, a relationship that was unsuspected until Dalton looked for it. This type of result, extended to include other simple ratios, has its general expression in Dalton's law of multiple proportions, which states that whenever two elements combine in more than one proportion by weight, the different proportions always bear simple ratios to one another. The improbability of such behaviour except on an atomistic basis is easy to recognize.

III. GASES AND THE MOLECULAR HYPOTHESIS

Dalton's theory, for all its success, left certain important questions unanswered. It did not lead to any conclusions whatsoever as to the absolute weights or sizes of atoms, and even in its determinations of the relative weights of different atoms it could not claim to be free of doubts and ambiguities. As an example of the latter, consider again the compounds of carbon with oxygen. There are two equally valid interpretations of the figures on the carbon oxides just quoted. If it is assumed that the first oxide has the formula CO, the second must have the formula C_2O because the measurements show that it contains only half as much oxygen relative to the same amount of carbon. On the other hand, if it is assumed that the second oxide is CO, the first must be CO_2 (which conforms to the true identification of these compounds as carbon monoxide and carbon dioxide respectively). It was the study of gases which resolved such questions as these and which also provided the first definite estimates of atomic size and weight.

1. Law of Combining Volumes.—In 1808 the chemist J. L. Gay-Lussac (1778–1850) discovered that when gases react chemically with each other, they do so in simple proportions by volume. For example, if a mixture of hydrogen and oxygen is detonated by an electric spark, the resulting reaction takes place in such a way that two volumes of hydrogen combine with one volume of oxygen to form two volumes of water vapour or steam. (For this result to be true, the volumes must all be measured at the same temperature and pressure.) The law of combining volumes, which summarized such behaviour, could be recognized as a counterpart of the law of definite proportions (whose concern was only with the weights of the reacting substances).

2. Avogadro's Hypothesis.—The extreme simplicity of these volumetric relationships led the Italian A. Avogadro (1776–1856) to propose in 1811 his hypothesis that equal volumes of different gases (at the same pressure and temperature) contain equal numbers of particles. But were these particles the same as Dalton's atoms? Avogadro took the position that in the gaseous elements well studied at the time (oxygen, hydrogen and nitrogen) the characteristic particle could not be a single atom, but must be two atoms of the element in close association. To illustrate this argument, consider the formation of water vapour from oxygen and hydrogen. If Avogadro's hypothesis is correct; the fact that two volumes of hydrogen react with one volume of oxygen means that two particles of hydrogen combine with one particle of oxygen. If the basic particle is a single atom in each case, the reaction may be written $2H + O \rightarrow H_2O$. But (applying Avogadro's hypothesis once again) this would imply that for each volume of oxygen consumed there would be only one volume of water vapour produced, which is contrary to observation. It would be possible to fit the facts by assuming that the smallest particle of hydrogen gas is a single atom but that the smallest particle of oxygen gas is a union of two atoms (O_2). The reaction could then be written $2H + O_2 \rightarrow 2(HO)$. On this evidence alone, there would be no need to assume that the smallest particle of hydrogen gas contains more than one atom. But, in another reaction known to Avogadro, three volumes of hydrogen combine with one volume of nitrogen to form two volumes of ammonia gas; this relationship cannot be achieved unless the hydrogen particle (and also the nitrogen particle) contains at least two atoms. This fact leads to the accepted statement of the oxygen-hydrogen reaction: $2(H_2) + O_2 \rightarrow 2(H_2O)$.

3. Molecules.—Out of such results arose not only a self-consistent account of chemical reactions, but also a recognition of the important and characteristic role played by what is normally the smallest particle of a gaseous substance—the molecule (*see* MOLECULE). The idea that the molecule of a pure element might consist of two or more atoms of that element was resisted by Dalton and others as being arbitrary and unreasonable. Why, for instance, if atoms of the same kind attract each other, should they stop short at aggregates of two or three instead of coalescing into one great cluster? But as the amount of chemical knowledge grew, it became increasingly clear that Dalton's scheme was inadequate, and finally (after 1858, when Avogadro's fellow-countryman S. Cannizzaro drew fresh attention to the logic of Avogadro's assumptions) the atomic-molecular theory as Avogadro conceived it became generally accepted.

IV. ATOMIC WEIGHTS

In 1860 an international conference on atomic weights officially adopted the Dalton-Avogadro scheme, and during the succeeding decades a highly accurate tabulation of the relative atomic weights of the elements was built up. It depended on the analysis of thousands of different compounds for which the molecular composition (*i.e.*, the numbers of different kinds of atoms per molecule) was assumed to be known. The risk of the sort of ambiguity that Dalton had suppressed (unreliably) through the rule of greatest simplicity was effectively eliminated by taking a sufficiently large variety of compounds.

1. Oxygen as Reference Standard.—For practical purposes, because only the ratios of the weights of different atoms were determined, the selection of one particular type of atom as a standard was necessary. Hydrogen, being the lightest atom, was first considered (by Dalton and others) as a standard. It had the disadvantage, however, that its compounds with other elements were limited in number and often difficult to handle chemically. Oxygen, on the other hand, formed stable and tractable compounds with most elements. Because the atomic weight of oxygen relative to hydrogen was known to be approximately 16, the decision was made (in 1902) to take the atomic weight of oxygen as precisely 16.000 . . . and to refer all other values to this figure. The list of atomic weights thus determined represented the culmination of the purely chemical approach to atomic theory, and was an important achievement.

2. Carbon as Reference Standard.—Early in the 20th century, it became known that the list did not express correctly the relative weights of individual atoms because one of Dalton's original assumptions is wrong. For most elements it is untrue to say that all the atoms are identical in weight; thus the chemical atomic weight is only an average taken over the different kinds of atoms of a given element (its isotopes) as they occur in nature (*see* ISOTOPE). That the composition of such mixtures should be almost the same for samples of a given element taken from different places on the earth is, of course, a noteworthy fact in itself. This loss of simplicity in the concept of a chemical element is offset to some extent by the fact that the weights of the different types of atoms of a given element cluster fairly closely around the average as expressed in the chemical atomic weight. However, the fact that the isotopic composition of oxygen itself is apparently not constant in nature led to the establishment in 1961 of a new set of values of atomic weights with an isotope of carbon as the reference standard. For a table of these values, and for more detailed information, *see* ATOMIC WEIGHT.

V. SIZE AND MASS OF ATOMS

If a molecule is regarded as a close association of atoms, the size of a molecule containing only a few atoms should not be very much greater than that of an individual atom. The determination of molecular sizes can thus be a useful step toward finding the sizes of individual atoms, and historically was the way of approaching this problem. The first quantitative estimates were obtained by Thomas Young (1773–1829) and presented by him in the *Encyclopædia Britannica Supplement* of 1816. Young based his conclusions on a study of surface tension and tensile strength of liquids. Although his conception of the relation between these two effects was substantially correct, his ignorance of the intimate structure of liquids and vapours led him to false conclusions, and (as mentioned earlier in this article) the first truly significant values of molecular size came from the study of gases.

1. Kinetic Theory; Avogadro's Constant.—One of the simplest and most direct deductions from the kinetic theory was that the molecules of gases must have very high speeds, of the order of 1,000 ft. per second. Seemingly opposing this deduction, however, was the fact that if a flask of, say, gaseous carbon dioxide is opened up to the air, no great amount of mixing of the two gases occurs over a period of hours. These results could be reconciled by ascribing to the molecules a diameter of such a size that any one molecule (at least in gas at normal atmospheric pressure) would travel only a minute distance before undergoing a collision with another molecule. In this way the movement or diffusion of the gas as a whole in a particular direction would be greatly discouraged. From the diffusive properties it is possible to estimate the average distance between successive molecular collisions. But this quantity, called the mean free path and denoted by the Greek letter λ, is determined from kinetic theory by the molecular diameter (d) and the number of molecules in a unit volume (n) according to the formula $\lambda = 1/\sqrt{2}\pi n d^2$. If, now, a volume V of gas or vapour, containing Vn molecules, condenses into liquid form so that the molecules are assumed to be densely packed, the volume (v) of condensed material cannot be less than $\pi V n d^3/6$, because $\pi d^3/6$ is the volume of a spherical molecule of diameter d. As a more realistic estimate take simply Vnd^3, because the packing of equal spheres does not fill space

completely. Multiplying v and λ together gives $v\lambda = Vd/\sqrt{2}\pi$, or $d = \sqrt{2}\pi\lambda(v/V)$. Experimental results show that for many gases $v = 0.005V$ approximately (*i.e.*, a given volume V of a gas at atmospheric pressure condenses to about $0.005V$ when converted to the liquid form of the substance) and that $\lambda = 2 \cdot 10^{-6}$ cm. approximately. This would mean that the diameter, d, of a molecule is equal to $5 \cdot 10^{-8}$ cm. very roughly, *i.e.*, about one fifty-millionth of an inch, or about $\frac{1}{1,000}$ of the wave length of green light. (No wonder, then, that individual atoms and molecules are invisible!)

As a further deduction from the same data, the number of molecules in a unit volume of a gas at atmospheric pressure can be obtained. With the figures just quoted, n turns out to be about $4.5 \cdot 10^{19}$ molecules per cubic centimetre. A determination of this number by the method just outlined was first made by J. Loschmidt in 1865. Of particular interest to chemists was the number of molecules in a gram-molecule (or mole) of substance; *i.e.*, the number in an amount of substance whose weight in grams is numerically equal to the molecular weight. It was known that a gram-molecule of a gaseous compound at standard temperature and pressure (0° C. and 1 atmosphere) occupies 22.4 l. or $2.24 \cdot 10^4$ c.c. According to the figures just derived, this volume would contain approximately 10^{24} molecules (*i.e.*, a trillion trillion in the U.S. system of numeration). It is implicit in the atomic-molecular theory that a mole of a chemical substance, under any conditions, has this number of molecules, and that a gram-atom of any element contains this same number of atoms, which is known as the Loschmidt number or Avogadro's constant. (The term Loschmidt number is also sometimes used to designate the number of molecules in just 1 cm.^{3} of a gas at standard temperature and pressure.) More accurate subsequent determinations by different methods (see *Proof of Existence of Atoms*, below) give its value as $6.0249 \cdot 10^{23}$ molecules per mole.

Knowledge of the Avogadro constant leads immediately to the absolute masses of atoms, or at least to the average isotopic mass for a given element. The masses are obtained by dividing the atomic weight by Avogadro's number. In this way it is found that, for the naturally occurring atoms, the masses range from $1.675 \cdot 10^{-24}$ g. (hydrogen) to $3.96 \cdot 10^{-22}$ g. (uranium).

2. Oil-Film Method.—Because of its extraordinary simplicity, a method of estimating molecular dimensions that was developed in 1890 by W. C. Röntgen and Lord Rayleigh deserves mention. It consists merely in depositing a tiny drop of oil on a water surface; the assumption is that the oil can spread until it forms a layer only one molecule thick. The limits of the oil patch can be seen by first sprinkling the water surface with a fine powder such as chalk dust or lycopodium powder. If the volume of the oil drop is V and the area of the resulting patch is A, the film thickness, and hence the molecular dimension, is V/A.

3. Atoms in Crystalline Solids.—For those chemical elements that exist in solid form, a good estimate of the atomic diameter can be made (given the value of Avogadro's constant) if it is assumed that the atoms are closely packed in a well-defined way—an assumption that the regular form of crystalline solids makes plausible. Thus, for example, a one-inch cube of the element copper has a mass of 146.4 g., and because the mass (isotopic average) of a single copper atom is $1.055 \cdot 10^{-22}$ g., it follows that the number of atoms in such a cube is $1.39 \cdot 10^{24}$. If the copper atoms are taken to be rigid spheres, packed as densely as the rules of geometry allow, these figures lead to the conclusion that the copper atom has a diameter of $2.56 \cdot 10^{-8}$ cm.

4. Variation of Size With Mass.—Similar, though less confident, estimates can be made for elements in liquid form, and the totality of results shows that atomic diameters all lie between about 1 and 5 angstrom units. (1 angstrom, designated by the symbol Å, is equal to 10^{-8} cm., and is a convenient unit of measurement on the atomic scale.) Thus there is far less variation in the sizes of the different atoms than in their masses. Moreover, contrary to what might be expected, there is no smooth increase of size with mass, although there are important regularities that can be understood in terms of the internal atomic structure (see *Atomic Structure and Periodic System*, below). One way of placing atomic size determinations on a common footing is to measure the volume occupied by a gram-atom of an element at its melting point. On this basis, which is admittedly somewhat arbitrary, the atoms of hydrogen and uranium appear to have almost the same effective size—a rather surprising conclusion. The largest atoms are those of the alkali metals (sodium, potassium, etc.) and the smallest are those of carbon and certain refractory metals (nickel, ruthenium, osmium, etc.).

VI. PROOF OF EXISTENCE OF ATOMS

It may seem strange to raise the question of the reality of atoms after discussing their actual properties in some detail yet for almost a century after Dalton laid its foundations the atomic theory remained just a theory, in the sense that the evidence for it was purely inferential. If, that is to say, chemists chose to assume the existence of atoms, the facts of chemistry could be nicely explained and they could even deduce (as indicated earlier in this article) the sizes and masses of the atoms; however, this did not constitute proof that an atomistic picture was correct. By the early 1900s all doubts had been swept away, and individual atoms were being counted and weighed. The two events that did most to bring about this advance were the discovery of the electron (*q.v.*) and the discovery of radioactivity (*see* RADIOACTIVITY).

1. The Electron.—The discovery of the electron, and the measurement of its charge and mass, were of immense relevance to atomic theory because of the intimate connection (first recognized by M. Faraday in 1833) between the transport of mass and the transport of electric charge in electrolysis. To deposit one gram-atom of an element by electrolytic methods requires the passage of an amount of electric charge which is equal to, or is a simple multiple of, a certain fixed quantity called the faraday (*see* ELECTROCHEMISTRY). For those who accepted an atomic theory of matter, this was clear evidence that electricity, also, must be atomistic, and that atoms carry one or more of the basic units of charge during electrolysis. With the identification of the electron the argument could be reversed, and so used to prove the reality of atoms. Moreover, the measured value of the electronic charge, divided into the faraday, furnished a new and corroborative value of Avogadro's constant.

An electric charge equal to that of the electron was identified as the unit charge not only in electrolysis, but also in the conduction of electricity through gases. It was recognized that in both processes there are both positive and negative charge carriers. In gas discharges at low pressure it was possible, by use of magnetic and electric deflections, to measure the ratio of charge to mass for the carriers. It was in this way that J. J. Thomson in 1897 showed that the negative carriers were isolated electrons, but at about the same time studies on the "positive rays," notably by W. Wien, revealed that these positive carriers had charge-to-mass ratios similar to those found in electrolysis, dependent on the nature of the gas in the discharge tube. This was fairly strong evidence that the positive part of the current was carried by individual atoms or molecules, although the proof was not completed until 1907, when Thomson developed more accurate methods of positive-ray analysis and showed that the mass per charge was sharply defined. This was the starting point of mass spectroscopy (*q.v.*) and the analysis of isotopes.

2. Radioactivity.—Even more direct and compelling, though at first less broad in its application, was the evidence from radioactivity. In 1903 J. Elster and H. Geitel (and also W. Crookes) observed that the so-called alpha radiation from a radioactive material caused separate and distinct flashes (scintillations) when it struck a screen of zinc sulfide. In the same year E. Rutherford, and independently T. des Coudres, observed the deflection of alpha rays in electric and magnetic fields, and showed that their ratio of charge to mass was similar to that of the positive rays formed in a hydrogen discharge tube. The next year (1904), in the first edition of his *Radioactivity*, Rutherford wrote: "In the scintillations of zinc sulfide, we are actually witnessing the effect produced by the impact . . . of single atoms of matter. . . ."

3. Brownian Movement.—It could well have been objected

that the phenomena of radioactivity and electricity did not supply any absolute proof that ordinary matter, in its normal state, has a granular structure; however, in 1908 (exactly 100 years after Dalton's theory was first propounded) the grounds for such objections were removed. In that year J. Perrin, testing a theory proposed in 1905 by Albert Einstein, made a detailed study of the ceaseless movement that microscopic objects undergo when immersed in a fluid. This motion, called "Brownian movement" (*q.v.*) after R. Brown, who first investigated it in 1827, could be interpreted as the direct and visible result of the buffeting of small objects by the still smaller (and invisible) molecules of the fluid. Such an explanation was put forward as early as 1877, but it was the work of Einstein and Perrin that showed how the motion, in all its quantitative details, could be explained through the kinetic theory of matter and could even be made the basis for yet another determination of Avogadro's number. After this demonstration the question of the reality of atoms became more a philosophic than a scientific one. It was, however, satisfying that within a few years the use of X-rays (*q.v.*) revealed the orderly arrangement of atoms in crystalline solids (W. Friedrich, P. Knipping and M. Laue, 1912) and provided direct measurements of interatomic distances (W. L. Bragg, 1913). Such measurements permit, in effect, a count of the atoms in a given volume of a crystal, and have become the basis of the most accurate of all determinations of Avogadro's constant.

4. **Field-Emission Microscopy.**—The nearest approach to seeing atoms directly is provided by the remarkably simple device known as the field-ion microscope, invented by E. W. Müller in 1951 as an outgrowth of his field-emission electron microscope of 1937. Both devices can be briefly described with reference to fig. 1, top. An exceedingly fine wire with a carefully rounded tip (T) is mounted in a cathode-ray tube. If a sufficiently high negative voltage is applied to the tip, electrons are driven out of it and go in straight lines to the screen S, where they cause bright fluorescent spots. The screen is not uniformly bright because the tip can never be made completely smooth on an atomic scale, and electrons are emitted most readily at corners or edges of the layers of atoms in the tip, where the electric field is greatest. If the radius of curvature of the tip is r, and the distance from tip to screen is R, the theoretical magnification of the microscope is R/r. For various reasons, including the wave properties of electrons (see *Wave Mechanics and Electron States*, below) superior performance can be achieved by making T positive instead of negative, and spraying the tip with atoms (especially helium) which settle on the tip for a short while and are then re-emitted as positive ions. With values for R and r in the region of 10 cm. and 1/100,000 cm. respectively, magnifications of a million or more can be obtained, and the array of spots on the screen is, in effect, a photograph at this enormous magnification of the positions of individual atoms in the emitting surface. Fig. 1, bottom, shows an example of the kind of picture obtainable.

VII. THE NUCLEAR ATOM

Thomson's researches on the mass and charge of electrons showed him that his results did not depend on the material from which the electrons are extracted. This fact led him to conclude that electrons were a universal constituent of all types of atoms. Actually, P. Zeeman and H. A. Lorentz had reached the same conclusion a year earlier (1896) through studies of the effect of magnetic fields on atomic spectra (*see* ZEEMAN EFFECT). It might have been tempting to contemplate the possibility that electric charges were the ultimate building blocks for all matter, but two facts stood out against this. First, no positive counterpart of the electron had been found; the lightest of the "positive rays" was about as massive as a hydrogen atom. Second, the electron was so light ($\frac{1}{1,837}$ the mass of a hydrogen atom) that very strained assumptions were needed to formulate a completely electrical theory of matter. Several attempts were made, however. Thomson himself came to favour the picture of a sphere of positive charge, occupying most of the volume of the atom, with electrons embedded in it. (He had concluded from the mass of the electron, assuming it to be pure electric charge, that its radius must be $2.8 \cdot 10^{-13}$ cm.; *i.e.*, only about $\frac{1}{50,000}$ of the radius of an atom.) P. Lenard in 1903 proposed a quite different model, according to which the atom was mostly empty space populated by small neutral doublets (close unions of positive and negative charges). His grounds for this view lay in some experiments he had made that showed atoms to be relatively transparent to fast electrons; he found, for example, that high-velocity electrons could pass through about 5,000 hydrogen molecules before being significantly deviated, or (to express a similar result in different terms) that the total impenetrable volume in a cubic yard of a very dense material, such as platinum, is smaller than a pin's head.

A picture almost identical with the one that was to gain final acceptance was put forward by H. Nagaoka in 1904. He proposed a "Saturnian atom" in which the electrons revolved in orbits around a central positive charge, like the particles of Saturn's rings around that planet. However, no strong evidence was offered in favour of this model at the time, and the credit for proving the existence of compact nuclei in atoms must unquestionably go to E. Rutherford.

1. **Alpha Particles.**—The evidence for the nuclear atom came from a series of experiments on the scattering of alpha particles by matter. The alpha radiation had been intensively studied; Rutherford and others had shown that the alpha particles were positively charged (with two units of the unit electronic charge) and in 1909 Rutherford and T. Royds proved, in a striking experiment, that alpha particles, upon coming to rest and being electrically neutralized, become identical with helium. With these projectiles, which had well-defined speeds of the order of one-tenth the velocity of light (which is about $3 \cdot 10^{10}$ cm./sec.) as a result of their ejection from radioactive atoms, Rutherford and his assistants bombarded thin foils of metallic elements. The crucial discovery, by H. Geiger and E. Marsden (1909), was the

occasional deflection of alpha particles through large angles (90° or more). Rutherford recognized that such a strong deflection of the alpha particle could only have been caused by collision of the particle with a small, massive center of electrical repulsion. (Note that a "collision," as defined in physics, can occur through the medium of long-range electric or other forces without involving any contact or interpenetration of the matter contained in the colliding particles.)

2. Rutherford Scattering Formula.—In 1911, Rutherford worked out the theory of the scattering on the assumption that the alpha particles were repelled by a concentrated positive charge according to the inverse square law of electrostatics (*see* ELECTRICITY: *Electrostatics: Coulomb's Law*). The Rutherford scattering formula is so important to the development of atomic theory that a derivation of it is given here. The calculation is in two parts. First, consider what would happen during a typical collision between an alpha particle and a nucleus. Suppose that the alpha particle, of mass m, speed v and charge $+2e$ (*i.e.*, twice the electron charge in size, but opposite in sign, the electron charge being designated by $-e$), is approaching a massive (and therefore almost immovable) nucleus of charge Ze, where Z is an integer specifying the magnitude of the charge. At large distances, before the electrical repulsion begins to take effect, the alpha particle moves in a straight line; this line is assumed to be offset a distance p from a straight line through the nucleus, as in fig. 2, top. As a result of the electrical repulsion the alpha particle is deviated as shown, so that when it is far removed from the nucleus it is again traveling in a straight line, but at an angle θ to its initial direction. Treating this as a problem in Newtonian mechanics reveals that the path taken by the alpha particle is a hyperbola, and that the distance p and the angle θ are related through the equation

$$\tan(\tfrac{1}{2}\theta) = \frac{2Ze^2}{mv^2p} \qquad (1)$$

It is convenient to introduce a certain distance b, representing the shortest distance between alpha particle and nucleus in a head-on collision. This "distance of closest approach" would be achieved by using up all the kinetic energy of the alpha particle to create electrostatic potential energy between the alpha particle and the nucleus; the condition is

$$\tfrac{1}{2}mv^2 = \frac{2Ze^2}{b} \qquad (2)$$

Making use of this condition, equation (1) simplifies to

$$\tan(\tfrac{1}{2}\theta) = \frac{b}{2p} \qquad (3)$$

This shows, of course, that the angle of deflection takes on larger values as p becomes smaller (and hence the repulsion stronger).

Now it is not in fact possible to prescribe the value of the distance p; any experiment on alpha-particle scattering consists simply of directing alpha radiation, in a well-defined direction, at a thin layer of scattering material. The alpha particles and the "target" nuclei cannot be individually localized, and the distribution of the various possible values of p is governed solely by the rules of chance. If, however, the frequency with which the alpha particles are scattered into the various directions θ as a result of these chance encounters is studied, an accurate analysis of the scattering mechanism becomes possible. For, referring to fig. 2, bottom, it is clear that all alpha particles passing through the shaded area (in the form of a circular ring of width dp and mean radius p) will have final directions between θ and $\theta + d\theta$. The area of this ring is $2\pi p\, dp$; thus equation (3) gives

$$p = \frac{b}{2}\cot(\tfrac{1}{2}\theta)$$

$$\therefore dp = -\frac{b}{4}\csc^2(\tfrac{1}{2}\theta)\, d\theta$$

$$\therefore 2\pi p\, dp = -\frac{\pi b^2}{4}\csc^2(\tfrac{1}{2}\theta)\cot(\tfrac{1}{2}\theta)\, d\theta \qquad (4)$$

Now the amount of solid angle contained between θ and $\theta + d\theta$ is $2\pi \sin\theta\, d\theta$, and a convenient measure of the effective area presented by a single nucleus for the purpose of deflecting an alpha particle through θ is obtained by dividing $2\pi p\, dp$ by this solid angle. This gives what is called the "differential cross section" $\sigma(\theta)$ for the scattering process, and the probability of a deflection through a particular angle is proportional to this cross section, which is given by the equation

$$\sigma(\theta) = \frac{b^2}{16}\csc^4(\tfrac{1}{2}\theta) \qquad (5)$$

Recalling the definition of b [equation (2)], equation (5) can also be written

$$\sigma(\theta) = \frac{Z^2e^4}{m^2v^4}\csc^4(\tfrac{1}{2}\theta) \qquad (6)$$

3. Nuclear Charge.—If the alpha-particle scattering is studied experimentally, it is possible in principle not only to test whether equation (6) correctly describes the dependence of $\sigma(\theta)$ on θ and v, but also to infer the value of the nuclear charge Ze. This is precisely what Rutherford, Geiger and Marsden proceeded to do during the years 1911–13. From one of the early measurements, in which a thin gold foil was the scatterer, Rutherford found the scattering as a function of angle to be well described by equation (6) with Z about 100. Knowing also the velocity of the alpha particles employed, he was able to conclude, with the help of equation (2), that the distance of closest approach, b, was about $3 \cdot 10^{-12}$ cm. The clear implication was that the nuclear radius must be less than this distance. A picture thus began to emerge of the atom as a structure in which nearly all the mass, together with a concentrated positive charge, is confined in an astonishingly tiny volume—certainly less than one hundred-billionth (10^{-11}) of the total volume of the atom. Outside this nucleus (*q.v.*) must lie a number of electrons at various distances from the nucleus, up to the established atomic radius; *i.e.*, 10^{-8} cm. or so.

Further measurements by Geiger and Marsden in 1913 confirmed Rutherford's scattering formula in a detailed manner for a number of different target elements, and indicated the nuclear

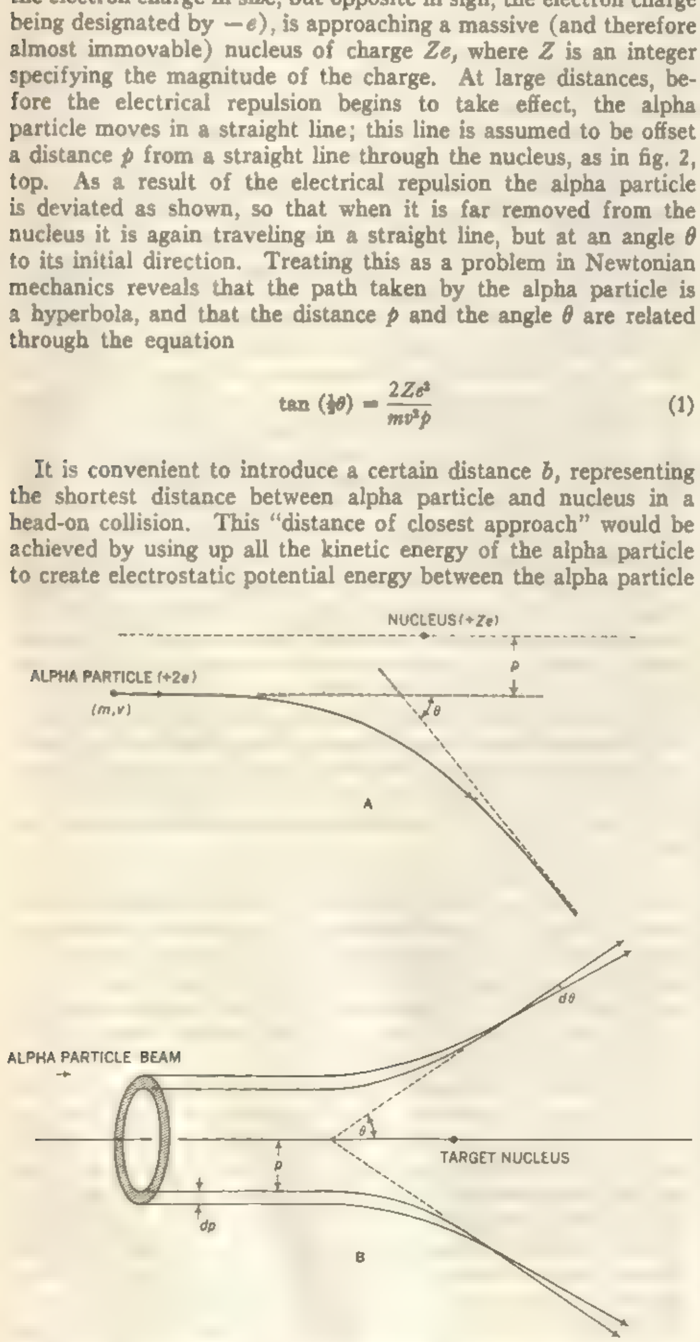

FIG. 2.—(A) DEFLECTION OF A SINGLE ALPHA PARTICLE BY A NUCLEUS; (B) EFFECTIVE CROSS SECTION (SHADED RING) FOR SCATTERING OF ALPHA PARTICLES BETWEEN θ AND θ + dθ

charge, Z, to be about half the chemical atomic weight. Because any atom is electrically neutral in its normal state, this discovery implied that the number of electrons in a given atom must be the same as the nuclear charge number, and, in fact, evidence to this effect was already extant. Lenard had found in 1895 that the attenuation of a fast electron beam is, to a good approximation, determined only by the mass of matter traversed and is independent of the chemical nature of the absorber. If it is assumed that electrons in the absorber are wholly responsible for the attenuation, then the number of electrons present is proportional simply to the mass of material, and thus, on an atomic scale, the number of electrons in any atom is proportional to its atomic weight. A similar conclusion was reached as a result of measurements made by C. G. Barkla between 1904 and 1911 on the scattering of X-rays by matter. (Thomson in 1906 devised theoretical interpretations and analyses of both the electron and the X-ray scattering experiments.) But all these measurements did little more than to indicate trends, and the clear-cut determination of nuclear charge was to come from quite another line of attack, which will be explained later.

VIII. BOHR'S ATOMIC THEORY

Rutherford's picture of atomic structure, though clearly necessitated by experimental evidence, left some crucial questions unanswered—and, indeed, raised some new ones. If the atom contained a concentrated positive charge at its centre, why were not the electrons drawn irresistibly into this centre? It did not answer the difficulty to suggest an analogy to the solar system, with electrons moving in orbits around the nucleus, because according to the laws of classical electrodynamics the electrons would, unlike the planets, be forced to radiate away their energy continuously and follow a shrinking spiral path that would bring them into the nucleus within a very short time. A related problem was to account in any reasonable way for the known sizes of atoms, which indicated that electrons persisted stably at distances of the order of 10^{-8} cm. (1 Å) from the nucleus.

1. Planck's Constant.—In 1913, Niels Bohr, recognizing (as indeed many did by that time) that classical physics was simply not adequate to describe systems of atomic size, made a radical and highly successful departure. In his own words: "Whatever the alteration in the laws of motion of the electrons may be, it seems necessary to introduce in the laws in question a quantity foreign to the classical electrodynamics." This quantity was Planck's constant, the "quantum of action." This famous constant, denoted by h, had first appeared in the theory of radiation from hot bodies; Max Planck in 1900 had shown that the spectrum of such radiation could be explained only if the radiation of frequency ν were "quantized" in packets of minimum energy $h\nu$, where $h = 6.625 \cdot 10^{-27}$ erg sec. (The physical dimensions of h are those of energy $\times$ time, or equivalently of momentum $\times$ distance; it was a quantity of the latter type that had been given the name "action" in classical mechanics.)

2. Atomic Spectra.—Bohr was guided mainly by some long-established regularities in the visible spectra of the elements, in particular the series of lines in the spectrum of atomic hydrogen (*see* SPECTROSCOPY). As viewed through a spectroscope, only four of the hydrogen lines are visible to the eye—a red, a green, a blue and a violet; many others, extending into the short-wavelength region of the ultraviolet, can be recorded photographically. J. J. Balmer in 1885 had shown that the measured wave lengths of these lines could be exceedingly accurately described (to about one part in ten thousand, in fact) by the formula

$$\frac{1}{\lambda_n} = R_H\left\{\frac{1}{4} - \frac{1}{n^2}\right\} \qquad (7)$$

where λ indicates wave length, R_H (Rydberg's constant for hydrogen), as evaluated by J. R. Rydberg in 1890, is approximately 109,677 cm.$^{-1}$, and n is a whole number whose successive values—3, 4, 5, etc.—characterize the lines of the spectrum in order of decreasing wave length or increasing frequency. It had been proposed by W. Ritz that equation (7) was merely a special case of the more general formula

$$\frac{1}{\lambda} = R\left\{\frac{1}{n_1^2} - \frac{1}{n_2^2}\right\} \qquad (8)$$

In seeking to explain such relationships with the help of the quantum hypothesis, Bohr first adopted a quite consciously naïve and even questionable approach, as follows:

Suppose that an electron, initially free and stationary, is drawn into a circular orbit of radius r around a nucleus of charge $+e$ (*i.e.*, a hydrogen nucleus). Let the mass of the electron be denoted by m and its orbital speed by v. To balance the electrical and centrifugal forces, the relation

$$\frac{e^2}{r^2} = \frac{mv^2}{r} \qquad (9)$$

is required. Now the total energy of the electron in its orbit is the algebraic sum of its kinetic energy E ($= \frac{1}{2}mv^2$) and its electrostatic potential energy $-e^2/r$. Use of equation (9) shows that this total energy is negative and equal to $-E$. Hence energy of amount E must be jettisoned, in the form of radiant energy, as the electron falls into its orbit. Furthermore, the frequency ν (revolutions per unit time) of the orbiting electron is given by $v/2\pi r$, and with the help of equation (9) ν can be found in terms of E:

$$\left.\begin{aligned} v &= \left(\frac{2E}{m}\right)^{\frac{1}{2}};\ r = \frac{e^2}{2E} \\ \therefore \nu &= \frac{1}{2\pi}\cdot\frac{(2E)^{\frac{3}{2}}}{m^{\frac{1}{2}}e^2} \end{aligned}\right\} \qquad (10)$$

Because the initial orbital frequency of the electron is zero, its average frequency during the transition is given by $\bar{\nu} = \frac{1}{2}\nu$. If this be identified with the frequency of the emitted radiation (which can be observed in a spectroscope if the frequency lies in the visible region), Planck's quantum hypothesis would demand that the amount of radiated energy be expressible as $nh\bar{\nu}$, where n is an integer. Now this amount of energy has already been given as E; therefore,

$$E = \frac{nh\nu}{2} = \frac{nh}{4\pi}\cdot\frac{(2E)^{\frac{3}{2}}}{m^{\frac{1}{2}}e^2}$$

whence

$$E = \frac{2\pi^2me^4}{h^2}\cdot\frac{1}{n^2} \qquad (11)$$

Consider now an electron jump between two circular orbits characterized by different values of n, and suppose that the change in electron energy is radiated away in a single quantum, of frequency ν and energy $h\nu$. Equation (11) then demands that

$$h\nu = \frac{2\pi^2me^4}{h^2}\left\{\frac{1}{n_1^2} - \frac{1}{n_2^2}\right\} \qquad (12)$$

Because the frequency and wave length of light (which is the type of radiant energy being discussed here) are related through the equation $\nu = c/\lambda$, where c is the velocity of light, equation (12) implies the result

$$\frac{1}{\lambda} = \frac{2\pi^2me^4}{ch^3}\left\{\frac{1}{n_1^2} - \frac{1}{n_2^2}\right\} \qquad (13)$$

Note that there is complete equivalence of form between this equation and the empirical equations (7) and (8). Moreover, Bohr's calculation was open to the most stringent of all tests, namely that the absolute value of the Rydberg constant R is specified in terms of known atomic and other constants. Using their numerical values as known at the time gives $2\pi^2me^4/ch^3 = 1.04 \cdot 10^5$ cm.$^{-1}$, with an experimental uncertainty of several per cent, as compared to the observed value of $1.10 \cdot 10^5$ cm.$^{-1}$ for R. The agreement was, in other words, as nearly perfect as the available data allowed, and the essential correctness of Bohr's theory as an explanation of the hydrogen spectrum could hardly be doubted.

3. Angular Momentum; Bohr's Postulates.—Having dem-

onstrated the numerical success of his theory, Bohr immediately reinterpreted its quantum aspects in a new and more fundamental fashion. Taking equation (11) for the kinetic energy of an electron in its orbit, and referring to the expressions for v and r in equations (10) gives

$$v = \frac{2\pi e^2}{nh}; \; r = \frac{n^2h^2}{4\pi^2me^2} \qquad (14)$$

Combining these results leads to the equation

$$mvr = \frac{nh}{2\pi} \qquad (15)$$

Now the quantity on the left side of this equation is the angular momentum of the electron in its orbit. Bohr therefore concluded that the quantity $h/2\pi$ represents a natural unit of angular momentum, and that only those motions for which this quantization holds are possible. In these terms the postulates of Bohr's theory can be stated as follows:

1. Electrons can move in circular (or, more generally, elliptic) orbits around the atomic nucleus.
2. The only orbits possible are those for which the orbital angular momentum is an integral multiple of $h/2\pi$.
3. These orbits are "stationary" in the sense that so long as an electron remains in a given orbit it radiates no energy.
4. An electron may jump from one orbit to a second orbit, of lower (more negative) energy, closer to the nucleus; in this process the energy liberated is emitted as a single quantum of light or other electromagnetic radiation.

The arbitrariness of these postulates was admitted, but their success was beyond dispute. Later the new atomic mechanics—called wave mechanics or quantum mechanics—led to the same results in a less forced manner (see *Wave Mechanics and Electron States*, below).

4. Size of Hydrogen Atom.—Besides accounting for the appearance and precise wave lengths of the sharp lines in atomic spectra, Bohr's theory set a definite size limitation on the hydrogen atom. The expression for the electron orbit radius in equation (14) shows that the possible radii are proportional to n^2; *i.e.*, to the squares of whole numbers. If the natural assumption is made that the normal state (ground state) of the atom has the electron in the orbit of lowest energy, then n would equal 1 and the corresponding radius would be $0.53 \cdot 10^{-8}$ cm. Thus the calculated diameter ($2r$) of a hydrogen atom is roughly 1 Å, in good agreement with the known order of magnitude of atomic dimensions.

IX. X-RAYS, ATOMIC NUMBER AND NUCLEAR CHARGE

Bohr's theory in its original application was confined to line spectra in the visible or near-visible region; *i.e.*, to radiations whose wave lengths are a few thousand angstroms. It was, however, known from the work of Barkla and others that the bombardment of substances by energetic electrons (accelerated through a potential difference of thousands or tens of thousands of volts) caused the production of so-called "characteristic X-rays." By 1913 it was well established that these X-rays are electromagnetic radiations similar to visible light but of much shorter wave length—of the order of a few angstroms only—and it seemed clear that these also should be considered within the framework of the Rutherford-Bohr atomic theory as quanta arising from electron jumps within the atoms of the bombarded material.

1. Moseley's Experiments.—In 1913 H. G.-J. Moseley (1887–1915) made a thorough study of these characteristic X-rays that could be excited in different elements by electron bombardment. His results demonstrated brilliantly that sharp spectral lines of various types could be traced in an absolutely regular fashion from the lightest to the heaviest elements (*see* SPECTROSCOPY; X-RAYS). When the square roots of the frequencies (or of the reciprocal wave lengths) for a given type of X-ray were plotted against the atomic weights of the elements, the points fell almost on a straight line. But a virtually perfect fit was obtained if, instead of atomic weight, the atomic number was used. The atomic number of a chemical element is the ordinal number of the element in the periodic system. (This arrangement places the elements, beginning with hydrogen, in an order that exhibits periodicities of chemical behaviour; it follows in the main the sequence of increasing atomic weights, but deviates from this order where necessary—*see* PERIODIC LAW.) As Moseley himself remarked, the X-ray spectra made it quite clear, without reference to any specific theory of atomic structure, that "these integers" (the atomic numbers) are truly characteristic of the elements. His measurements, however, did even more than this. For, taken in conjunction with Bohr's theory, they proved beyond any reasonable doubt that the chemical atomic number is to be identified with the number of units of positive charge carried by the nucleus—a possibility first suggested by A. van den Broek in 1913.

To show how compelling the argument is, consider a modification of the calculations just obtained for the hydrogen atom to cover the case where an electron moves around a central charge Qe instead of just e. The result, quite readily arrived at, is that equation (12) must be replaced by the equation

$$h\nu = \frac{2\pi^2me^4Q^2}{h^2}\left\{\frac{1}{n_1^2} - \frac{1}{n_2^2}\right\} \qquad (16)$$

Now it is extremely plausible that a given type of X-ray transition, occurring in a series of different elements, is characterized always by the same values of n_1 and n_2, so that only Q is changed in going from one element to another. If this is so, a graph of $\sqrt{\nu}$ against Q will be a straight line. Furthermore the slope of this line is determined solely by the values of n_1, n_2 and the atomic constants in equation (16), and Moseley's results showed that quantitative agreement was obtained for simple integral values of n_1 and n_2. (Actually the pair of values $n_1 = 1$, $n_2 = 2$ defined one set of lines; $n_1 = 2$, $n_2 = 3$ defined another.) The value of Q does not necessarily define the nuclear charge itself, because in a many-electron atom there may be some electrical screening of the nucleus by electrons lying very close to it. This possibility however, did not obscure the clear implications of the experimental results.

2. Origin of X-Ray Spectra.—It is noteworthy (and, from the point of view of Moseley's work, very fortunate) that the X-ray spectra are among the simplest of all atomic spectra, and show none of the apparently capricious variations that occur in the visible spectra of the elements. The reason is that the X-ray quanta come from transitions between a few of the innermost electron orbits, near to the nucleus and dominated by it, and the only important effect of increasing the nuclear charge is to make these orbits smaller. (Use of the simple Bohr theory shows that the orbit radius is inversely proportional to Q.) The transitions in the visible region of the spectrum, however, involve the valence electrons (the electrons on the outer fringe of the atom), which are strongly influenced by other electrons in the atom and whose number and disposition vary with the atomic number in a sensitive and far from continuous manner. It is easy to see, therefore, why Moseley's X-ray measurements made such a distinctive and important contribution to the understanding of atomic structure.

X. ISOTOPES AND THE NUCLEUS

Although the value of the atomic number (usually denoted by Z) serves to define a given chemical element, it does not necessarily define a unique kind of atom. This is because of the existence of isotopes (*see* ISOTOPE). The classification of the various kinds of atoms by element and atomic number is only a partial breakdown; there are 80 different stable elements on earth, but these comprise a total of 284 distinct atomic species. The classification by Z works quite well for the chemist, because chemical behaviour depends almost entirely on atomic number. Mass does play a part, because a heavy isotope moves more sluggishly than a light one at the same temperature, and this can influence (though only to a very small degree) chemical reactions and chemical equilibria—a fact that has been exploited in fascinating ways; *e.g.*, in paleoclimatology. But to the physicist, and particularly to the nuclear physicist, the different isotopes of an element may appear as radically different types of atoms, and the classification accord-

ing to atomic number may for this purpose be irrelevant and even undesirable. To pursue this particular matter would involve a study of the nucleus as such, which is the concern of a separate article (*see* NUCLEUS). A few statements about the basic properties of atomic nuclei are, however, relevant and necessary to present an adequate picture of the atom.

1. Protons and Neutrons.—The positively charged unit in nuclear structure is the proton (*q.v.*); it is the nucleus of the lightest atom found in nature, viz., the most abundant isotope of hydrogen. The observation had been made, even before the discovery of isotopes, that the atomic weights of many elements are close to integral multiples of the atomic weight of hydrogen, and the presumption that protons are building blocks of the heavier nuclei was a strong one. It was clear, however, that protons alone would not suffice, because the ratio of the atomic number to the atomic weight is less than one-half in all elements except hydrogen (for which it is almost exactly 1). Two possibilities presented themselves: either (1) the atomic weight is the true index of the number of protons in the nucleus, and the nuclear charge is reduced to the value Ze through the presence, within the nucleus itself, of a number of electrons (which would contribute exceedingly little to the mass); or (2) the atomic number Z is a correct measure of the number of protons in the nucleus, and the balance of the mass is provided by a number of electrically neutral particles of about the same mass as a proton. The discovery of the neutron (*q.v.*) in 1932 gave solid grounds for the conviction, which had been growing for about ten years prior to that date, that explanation (2) is the correct one.

2. Mass Number.—A particular atomic species, or "nuclide" (the term was coined by T. P. Kohman in 1947), is thus characterized by its number of protons, Z, and its number of neutrons, N. The sum of these two integers is the mass number, A. The actual mass of any atom is thus the result of combining Z protons, N neutrons, and Z orbital electrons; this total mass is somewhat less than the sum of the masses of the individual constituents, because energy E (and hence the mass equivalent of that energy, defined by $M = E/c^2$, where c is the velocity of light and M is the difference between the total mass of the constituent particles and the mass of the atom) is given up in forming this tightly bound system. Because the masses of both the proton and the neutron are quite close to 1 when referred to the atomic weight scale, and because the mass of all the electrons in any atom is less than $\frac{1}{1,000}$ of the whole, the total mass of an atom on the atomic weight scale is a number (though not an integral number) close to the integer A. Its precise numerical value depends on the arbitrary choice of a certain standard (see *Atomic Weights*, above.)

3. Nuclear Size.—Besides having specific values of Z, N and A, a nucleus has a quite well definable size. The extension of nuclear scattering experiments of the Rutherford type and a variety of other methods shows that nuclear radii lie between about $1.5 \cdot 10^{-13}$ cm. and 10^{-12} cm. Moreover, there is a systematic dependence of size on mass, according to the formula $R = r_0 A^{1/3}$, with $r_0 = 1.2 \cdot 10^{-13}$ cm. approximately. This means that the nuclear volume, unlike the volume of the atom as a whole, is rather closely proportional to the atomic mass, and hence that the densities of all nuclei are about the same. The value of this density is staggering—about 100,000 tons per cubic millimetre. It is not surprising, therefore, that nuclear matter has properties peculiar to itself, and that nuclear physics has acquired the status of a separate area of study, distinct from what is normally called "atomic physics." The magnitude of nuclear radii implies that the nucleus occupies an even smaller fraction of the total atomic volume than Rutherford's early experiments had indicated; the fraction varies from about 3 parts in 10^{13} for the lightest atoms to about 1 part in 10^{12} for the heaviest. Nevertheless the nucleus, with its relatively great mass and its centrally located positive charge, dominates the properties of the atom as a whole.

XI. ENERGY LEVELS OF ATOMS

The emission by atoms of sharp spectral lines, in both the visible and the X-ray regions of wave lengths, is clear evidence that an electron in an atom is not allowed to possess any arbitrary amount of energy, but is limited by the laws of quantization. In the simple Bohr theory of circular orbits, for example, the energy is specified by a single quantum number, n [*cf.* equation (11)].

1. Electron Ejection.—Confirmation of this situation comes from experiments in which electrons are knocked out of atoms in a carefully controlled way. This can be done by bombarding atoms with electrons of a well-defined velocity, or with electromagnetic radiation of a well-defined wave length. (The latter phenomenon is the external photoelectric effect; *see* PHOTOELECTRICITY.) The results show clearly that unless a certain minimum amount of energy is supplied, a given electron within the atom cannot be dislodged; the interaction between atom and bombarding agent is an elastic one, and the bombarding electron or quantum of electromagnetic radiation bounces off with no loss of energy. If, however, the minimum or threshold energy is just barely exceeded, a drastic interaction can take place; the atom absorbs all the energy of the bombarding agent, and in return ejects one of its electrons. (The process has a rough analogy to devices sometimes found at fairgrounds, on which a sufficiently vigorous sledgehammer blow will win a prize, but anything less is worth nothing.) If more than the minimum energy is supplied, the ejected electron will possess the surplus in the form of kinetic energy. Experiments with electromagnetic radiation are particularly amenable to accurate measurement, and show that the threshold conditions for removal of electrons are exceedingly sharp; the effect manifests itself as an abrupt increase in the absorption of radiation by the atom at certain wave lengths.

2. Absorption Edges.—If the absorption by atoms of a given type is measured for electromagnetic radiation of steadily increasing frequency (and therefore of increasing quantum energy), a whole succession of critical "absorption edges" can be observed. From the value of each critical frequency (or wave length) of the radiation, it is possible to deduce how much energy is required for the purpose, and hence how far down (on an energy scale) the various electrons are within the atom. A convenient unit of measurement for such energies is the electron volt (ev), defined as the amount of energy equal to that gained by an electron when accelerated through a potential difference of one volt. (1 ev $= 1.602 \cdot 10^{-12}$ erg.) The energy of a quantum of radiation of wave length λ (measured in angstroms) is approximately $12{,}400/\lambda$ ev; thus the energy for visible light of several thousand angstroms wave length is a few ev per quantum, and an X-ray quantum of a few angstroms wave length has an energy of some thousands of ev. Most atoms exhibit critical absorption phenomena at a number of energies over this range. In the case of barium ($Z = 56$), for example, critical conditions for removal of a single electron occur at quantum energies of 5.19 ev, 47.5 ev, 255 ev, 1,300 ev, 5,955 ev and 37,432 ev. This list is not exhaustive, but does bring out the main feature, namely that the electrons lie in a limited number of widely-spaced energy levels.

3. Electron Shells.—In the Bohr picture, these energy levels correspond to a succession of electron shells, with the most tightly bound electrons in a shell of small radius close to the nucleus (known as the K shell in spectroscopy) and other shells (L, M, N, etc.) of less tightly bound electrons at greater radial distances. This relatively simple geometrical model has been untenable since the advent of wave mechanics, but the reality of the well-defined energy levels survives. The great variation in binding energy for electrons in the K shells of different elements is noteworthy (though quite understandable with the help of equation [16]). In hydrogen ($Z = 1$) it is 13.6 ev; in uranium ($Z = 92$) it is 115,000 ev.

If an electron is driven completely out of an atom by the methods described, the atom proceeds to readjust itself by one or more quantum jumps until the stable state of lowest energy is regained. Because one electron has been lost from the atom at the beginning of the process, achievement of this final state cannot be completed until another electron has somehow been picked up. The general process of readjustment is accompanied by the emission of quanta of radiation; the preceding paragraphs, in other words, describe one way in which atoms can be excited so as to emit their characteristic spectral lines. In general, the radiation

thus produced is in the ultraviolet to X-ray region; the only significant exception is when one of the most weakly bound electrons, in the outermost shell, is ejected and is replaced by an electron which, in the process of falling into the vacated level, undergoes a succession of radiative transitions of low energy. Only those quanta having energy between about 1.5 ev and 3 ev lie in the visible region, which illustrates how little of the energy scale of atomic phenomena is accessible to our ordinary senses.

Despite the very small energy gap between an atom in its normal (neutral) state and an atom with one of its outermost electrons removed (*i.e.*, a positive ion), a very large number (in principle, an infinite number) of so-called excited states are available to the neutral atom within this gap; such excited states are for the most part quite short-lived (of the order of 10^{-8} sec.). The energy difference between the ground state and an excited state is called an excitation potential. A large part of spectroscopy has consisted of identifying all the observed spectral lines of an atom as transitions between a limited number of excited states, and so mapping out the energy level structure.

It is clear, from this picture of the energy levels in a typical atom having many electrons, that the electrons are not all free to drop down to the most strongly negative energy states; otherwise they would all be found in the K shell. In fact, the conclusion that each possible energy region can accommodate only a limited number of electrons seems to suggest itself. This, then, is a new principle, not contained or in any way implied in the Bohr theory, and its precise formulation is of the greatest importance to atomic theory. Before discussing this, however, it is appropriate to reconsider the general picture of electrons in atoms in the light of wave mechanics.

XII. WAVE MECHANICS AND ELECTRON STATES

The discovery in 1927 that the electron, theretofore regarded as a particle, has certain wave properties inseparably associated with it demanded a completely new description of situations and phenomena on the atomic scale. This description was provided by the mathematical system known as wave mechanics or quantum mechanics (*q.v.*). Its starting point was the experimental fact that an electron of mass m and speed v behaves as though it has a wave length λ equal to h/mv, where h is Planck's constant.

1. Standing Waves.—For free electrons (*i.e.*, those not bound in atoms), this wave character manifests itself in their ability to be diffracted like light or X-rays, but for electrons confined within an enclosure (and the interior of an atom is an enclosure of sorts) a new phenomenon appears—that of standing waves. The consequences of this can be visualized to some extent with the help of an analogy from the world of music. An organ pipe (or the body of any other wind instrument) is an enclosure for sound waves. Moreover, because this enclosure has a well-defined length, only certain wave lengths of sound can be accommodated within it, namely those that are simple submultiples of the length of the pipe. At these wave lengths, and at no others, it becomes possible for the air column within the pipe to undergo strong vibrations, with successive minima (nodes) and maxima (antinodes) of vibration at fixed positions along the length of the pipe, separated by quarter-wave-length intervals. The result of this is that the frequencies of the sounds obtainable from the pipe are limited to simple numerical multiples of a certain fundamental frequency. The equivalent problem in wave mechanics would be that of an electron confined between rigid walls a distance l apart. The permitted wave lengths would be those that allow a node at each end; these are given by $\lambda = 2l, l, 2l/3$, etc., or in general by $\lambda = 2l/n$, where n is an integer. However, because $\lambda = h/mv$, this result demands that $v = nh/2ml$ and, using the equation $E = \frac{1}{2}mv^2$ for the kinetic energy of the electron, it is seen that the only allowed values of E are defined by the equation

$$E = \frac{n^2h^2}{8ml^2} \tag{17}$$

The integer n thus appears in the role of a quantum number for the system. Moreover, the minimum possible energy of the system, defined by $n = 1$, is seen to be inversely proportional to l^2—the smaller the space into which the electron is compressed, the larger its kinetic energy must be.

2. Electron Energies.—Although the result just obtained is not applicable, as it stands, to the problem of electrons in atoms it does contain certain features—the existence of quantum numbers and the inverse relationship between kinetic energy and dimensions—that are basic both to an electron in an atom and an electron confined between two rigid walls. Note, however, that there are at least two important differences. First, the atomic problem is essentially a three-dimensional one. Second, the atom is not a hollow enclosure with rigid walls. A hollow and completely rigid enclosure is one in which a particle experiences no force at all until it encounters the wall, at which point the force becomes infinite. The atom, however, from the point of view of a single orbital electron, behaves as the centre of an attractive force which exists at all points, but whose magnitude gradually decreases to zero as the distance r from the centre becomes large. Such a force derives from a negative potential energy, $V(r)$, whose value for a single electron in the field of a positive point charge Ze is given by $V(r) = -Ze^2/r$. This potential is illustrated in fig. 3, top. The effective wave length λ for an electron of fixed energy E in this potential region is not constant, but is given by the equation

$$\lambda = \frac{h}{mv} = \frac{h}{\{2m[E - V(r)]\}^{\frac{1}{2}}} \tag{18}$$

The wave length becomes larger as $E - V(r)$ decreases; *i.e.*, as r increases.

This "electron wave" is described by a wave equation, called Schrödinger's equation, whose classical analogue is that of a wave passing through a medium of continuously varying refractive index. And although the possibility of having standing waves with well-defined wave lengths is now ruled out, the existence of stationary vibrations with well-defined energies is not. It turns out, in fact, that the total energy E, if negative, is limited to values given by the equation

$$E_n = -\frac{2\pi^2Z^2me^4}{h^2}\cdot\frac{1}{n^2} \tag{19}$$

This result is identical with the negative total energy of an electron as given by Bohr's theory, and note that once again $n = 1$ defines the lowest (most negative) energy state. The energy level structure is indicated in fig. 3, bottom; for positive E there are no restrictions on the precise value the energy may have.

3. Wave Function; Effective Charge Distribution.—It is striking that the same results as Bohr obtained should also come from the wave-mechanical approach. There are, however, some

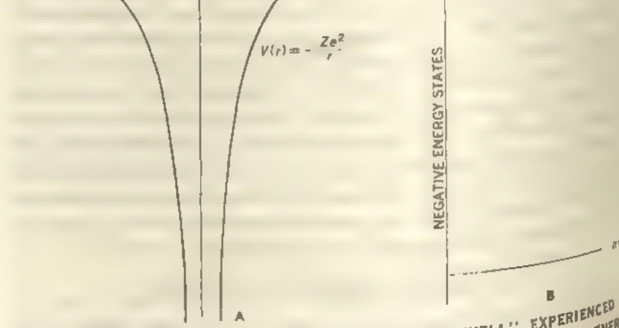

FIG. 3.—(A) SECTION ACROSS THE "POTENTIAL WELL" EXPERIENCED BY AN ELECTRON IN THE FIELD OF A NUCLEUS OF CHARGE Ze; (B) ENERGY LEVELS FOR A SINGLE ELECTRON IN THE POTENTIAL (A)

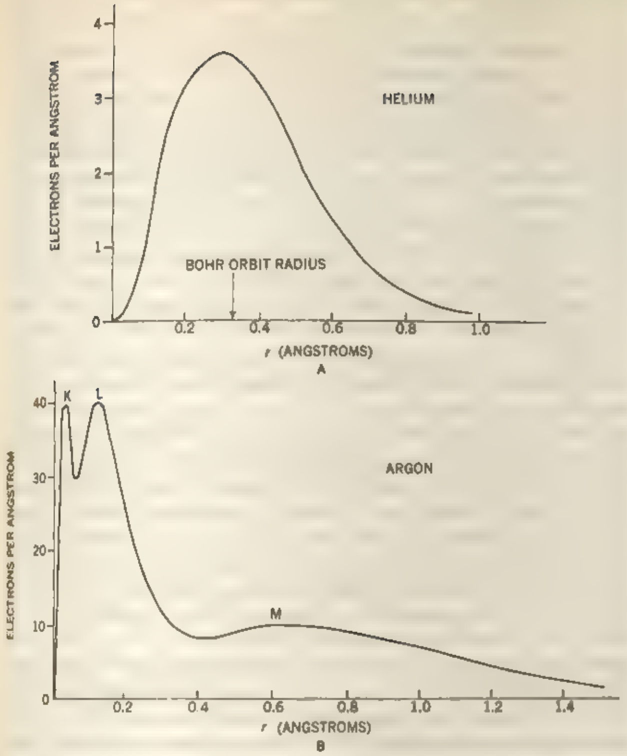

FIG. 4.—RADIAL CHARGE DISTRIBUTION OF THE ELECTRON CLOUD IN ATOMS. ORDINATE IS $4\pi r^2\rho(r)$, WHERE $\rho(r)$ IS THE CHARGE PER UNIT VOLUME AT RADIUS r. TOTAL AREA UNDER EACH CURVE REPRESENTS TOTAL NUMBER OF ELECTRONS IN THE ATOM. (A) HELIUM, STUDIED BY X-RAY DIFFRACTION (AFTER E. O. WOLLAN); (B) ARGON, STUDIED BY ELECTRON SCATTERING (AFTER L. S. BARTELL AND L. O. BROCKWAY)

very important differences. First among these is the disappearance of the concept of a well-defined orbit radius. Instead, the electron is described by a "wave function" which defines the probability of finding the electron at any particular location. This probability is usually high at distances corresponding to the Bohr radii, and falls away rapidly toward zero for large r. As a result of this lack of definiteness in its position, the electron behaves as though it were a smeared-out distribution of electric charge, instead of a point charge. By studying the scattering of X-rays or electrons from isolated atoms, this effective charge distribution can be mapped out, and fig. 4 shows experimental results for helium ($Z = 2$) and for argon ($Z = 18$). In the former case there is a single maximum at a radius close to that computed for $n = 1$, $Z = 2$ in Bohr's theory. In the latter case there is evidence for three maxima, which can plausibly be associated with the existence of three electron shells in argon (K, L and M) corresponding to $n = 1$, $n = 2$, and $n = 3$ respectively. But the many-electron system is a complex one, and before going further some other aspects of the one-electron problem must be mentioned.

4. **Quantum Numbers.**—No reference has yet been made to the orbital angular momentum, which was the main basis of Bohr's method of quantization. This quantity appears, however, when the circulation of the electron around the nucleus, as described by the electron's wave function, is considered. Crudely speaking, the charge cloud representing a single electron has some of the properties of a top; to describe its rotation necessitates a measure of how vigorously it is rotating, and also of how it is tilted in space. This introduces two new quantum numbers, l and m_l, in addition to the "principal quantum number," n. The magnitude of the rotation, as specified by the angular momentum L, is given by

$$L = \sqrt{l(l+1)}\frac{h}{2\pi} \tag{20}$$

This, then, is the analogue of equation (15) in Bohr's theory. The orientation of the charge cloud with respect to some physically defined direction (*e.g.*, that of a magnetic field) is defined by the component of L along that direction, and can be described by angles θ_m, which may have values such that $\cos\theta_m = m_l/\sqrt{l(l+1)}$. For any particular value of l, m_l may take on values $l, l-1, \ldots, 0, \ldots, -l$; *i.e.*, $2l+1$ different possibilities. Also, for any particular value of n, l is limited to the values $0, 1, \ldots, n-1$; *i.e.*, n distinct values.

A set of particular numerical values for the three quantum numbers n, l and m_l would completely specify the state of an electron in wave mechanics except for one thing, namely that the electron behaves as though it has a spin that restricts it to being oriented "up" or "down" with respect to a magnetic field or other specified direction. This property is most simply described mathematically by introducing a spin quantum number m_s that is either $+\frac{1}{2}$ or $-\frac{1}{2}$. This gives, finally, a set of four quantum numbers (n, l, m_l, m_s) that completely specifies the state of an electron in an atom.

XIII. ATOMIC STRUCTURE AND PERIODIC SYSTEM

There is one additional condition that makes intelligible the arrangement of electrons in a many-electron atom. This condition, called the exclusion principle (W. Pauli, 1925), asserts that no two electrons in the same atom can have the same set of four quantum numbers. To see what this entails, suppose that there is a "bare" nucleus of charge Ze to which electrons can be added one by one. The first electron will drop down into the lowest available state, which is characterized by $n = 1$, $l = 0$, $m_l = 0$. The second electron can do the same, provided that one electron has $m_s = +\frac{1}{2}$ and the other has $m_s = -\frac{1}{2}$. But at this point the possibilities for $n = 1$ have been exhausted; there is a closed shell (the K shell) of just two electrons. The third electron to be added is compelled to enter one of the next higher levels, with $n = 2$. This electron is much less strongly bound [*cf.* equation (19)], and on the average is much further from the nucleus than are those in the K shell. Now the quantum state for which $n = 2$ allows $l = 0$ and $l = 1$; moreover, because of the doubling allowed by the spin, there are $2(2l+1)$ different sets of quantum numbers (and hence electron states) for a given value of l. This means that the $n = 2$ shell (which is the L shell) can accommodate $2 + 6 = 8$ electrons, at which point it is filled and a shell of even more weakly bound electrons, with $n = 3$, (the M shell) must begin to form. The process is complete, of course, when a total of Z electrons has been added.

The more obvious features of chemical behaviour follow readily from this picture. The closed electron shell represents a chemically stable structure, and is illustrated by the noble gases (helium, neon, argon, etc.). The addition of one or two electrons beyond a closed shell gives a looser structure. It is relatively easy to detach these extra electrons and thus leave a surplus of positive charge in the system as a whole; this is the basis of chemical reactivity and of the formation of positive ions. Electronic structures of this type represent typical metals. On the other hand, a structure that is short of a closed shell by one or two electrons will acquire further stability by completing the shell, thereby becoming a negative structure; here there is the possibility of forming negative ions from typical reactive nonmetals such as oxygen and chlorine. (*See* VALENCE.)

By considering the progressive change of Z from 1 up to about 100 the periodic system of the elements can be built up, and it can be understood, for example, why the atomic volumes of the elements show abrupt increases at the alkali metals, which have just one loosely bound electron outside a closed-shell structure. The lack of any great general change in atomic sizes from one end of the periodic table to the other is also easily understood by recognizing that the closed electron shells of an atom of large Z make it appear to its outermost electrons like an atom with a central charge considerably smaller than Z.

XIV. UNSTABLE ATOMS

The principal concern of this article is a consideration of the existence and structure of normal, stable atoms of the elements. It is important to point out, therefore, that the number of different atomic species represented by these is greatly exceeded by

a variety of unstable or metastable atomic types. Apart from the naturally radioactive elements, which include all isotopes of the elements with Z greater than 82, *i.e.*, beyond lead, most of the unstable atoms are artificially produced isotopes of elements whose stable isotopes are found in nature. About a thousand unstable atomic species, with lifetimes ranging from about 10^{-21} sec. to millions of years, had been established by 1960. Instability of this type is nuclear instability, and its most usual cause is an abnormal ratio of neutrons to protons in a nucleus of given mass number.

1. Mesonic "Atoms"; Positronium.—A completely different type of unstable "atom" can be made by replacing orbital electrons with some other sort of negatively charged particles. In particular, such atoms have been made with negative mesons (μ or π). These particles are several hundred times more massive than the electron, but carry the same electric charge (*see* PARTICLES, ELEMENTARY). The result is that they can form Bohr orbits which are several hundred times smaller in radius than the corresponding ones for electrons. [This can be seen by reference to equation (14).] These mesonic (or mesic) atoms normally consist of a nucleus plus one meson, and so are similar to a hydrogen atom except that the central charge may be that of any nucleus. (The electrical neutrality of the atom is preserved by the continuing presence of electron shells far outside the meson orbit.) These atoms live only a very short time, because the meson either decays (being itself an unstable particle) or else is captured by the nucleus. A related type of unstable "atom" is a unique species, called positronium, composed of one electron and one positron (positive electron). One could call positronium an atom of mass number equal to zero. It can exist in two forms, but each has a very short life (about 10^{-7} sec. and 10^{-10} sec. respectively) which is terminated by the mutual annihilation of electron and positron.

2. Antimatter.—The discovery of the antiproton in 1955 and of the antineutron in 1956 confirmed a long-standing belief that all three of the constituents of normal atoms (*i.e.*, proton, neutron and electron) have antiparticles (mirror images, in a sense) that differ from their counterparts by having electric charges (in the case of the proton and electron) and magnetic moments of the opposite sign. This suggests the intriguing possibility that there may exist, somewhere in the universe, whole worlds made up of atoms of antimatter. An atom of antimatter would have a negatively charged nucleus, composed of antiprotons and antineutrons, surrounded by a cloud of positrons. In all its properties, except those depending directly on the reversal of charge and magnetism, it would be identical with (and just as stable as) a normal atom of the same Z and N; its energy levels would be precisely the same, and hence all its spectral lines would be indistinguishable from those of the normal atom. But if antimatter exists in any continuing way, it must be in regions quite devoid of normal matter, because any encounter between the two would result in their mutual destruction, with the release of vast amounts of radiant energy.

XV. ATOMICITY IN GENERAL

It seems that atomicity is one of the fundamental features of the material world. In this article it has been exhibited how electric charge, as well as mass, exists in basic and apparently indivisible units. Frequent reference has also been made to the manner in which radiation is emitted as discrete quanta. There is another side to the picture, however. Whereas, historically, man's detailed knowledge of radiant energy (light, X-rays, etc.) began with its wave properties and only later uncovered its atomistic qualities, man's knowledge of particles (electrons, protons, neutrons, etc.) was at first dominated by evidence of their atomic nature. The discovery of electron diffraction and of wave mechanics led to the realization that wave properties and corpuscular properties are not in fact separable on the atomic scale; neutral atoms can be diffracted like X-rays, as was first demonstrated by I. Estermann and O. Stern in 1930. Nevertheless the concept of the atom as a well-defined unit of matter, although becoming incomparably more detailed, remains as real as it was to the first atomists. *See* also Index references under "Atom" in the Index volume.

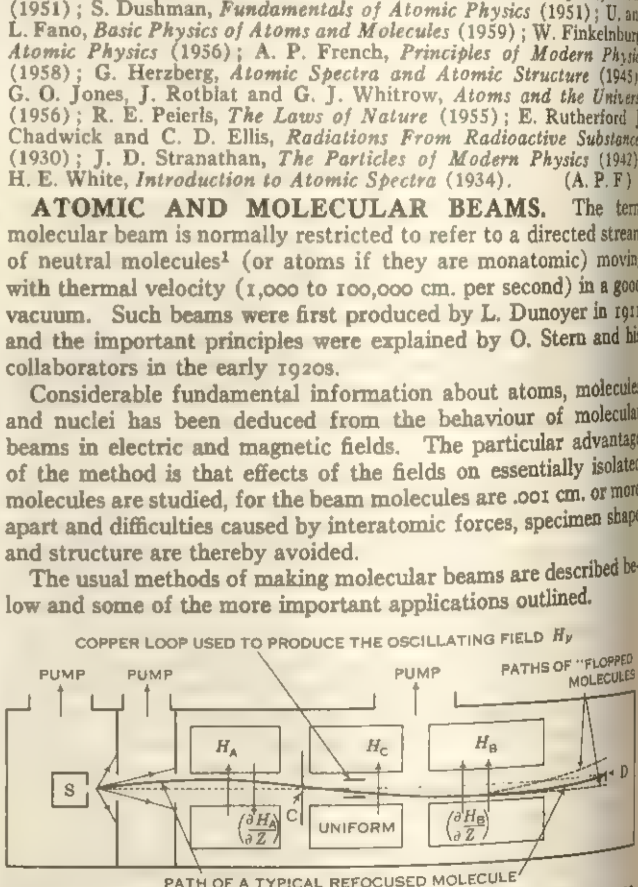
ATOMIC AND MOLECULAR BEAMS. The term molecular beam is normally restricted to refer to a directed stream of neutral molecules[1] (or atoms if they are monatomic) moving with thermal velocity (1,000 to 100,000 cm. per second) in a good vacuum. Such beams were first produced by L. Dunoyer in 1911 and the important principles were explained by O. Stern and his collaborators in the early 1920s.

Considerable fundamental information about atoms, molecules and nuclei has been deduced from the behaviour of molecular beams in electric and magnetic fields. The particular advantage of the method is that effects of the fields on essentially isolated molecules are studied, for the beam molecules are .001 cm. or more apart and difficulties caused by interatomic forces, specimen shape and structure are thereby avoided.

The usual methods of making molecular beams are described below and some of the more important applications outlined.



SCHEMATIC DIAGRAM OF A TYPICAL MOLECULAR BEAM MAGNETIC RESONANCE APPARATUS

Formation of a Molecular Beam.—The arrangement of a typical modern apparatus is shown in the figure. Molecules in the source S, where the pressure is p_s and the mean free path between collisions is λ_s, effuse through the source aperture, which is usually round (radius a) or rectangular (width a), into a well-evacuated space. If λ_s is much greater than a, the beam molecules suffer no further collisions until they hit a wall or a defining aperture, and the beam falling on the detector D consists of the molecules selected by the collimating slit C; the remainder of the molecules leaving the source (normally only about .001% of the molecules are used) are condensed on liquid-air-cooled surfaces or pumped away. Higher source pressures, such that λ_s is less than a, result in the formation of a turbulent cloud near the source aperture, the effective source width increases but θ, the beam intensity at the detector, does not increase proportionately unless the

[1]In this article, both atoms and molecules will be called molecules unless the distinction is important.

The pumps and traps must maintain a pressure in most of the apparatus (about 10^{-6} mm. mercury or less) such that λ, the mean path between collisions with residual molecules, is much less than L, the length of the beam, or attenuation of the beam intensity by a factor $e^{-L/\lambda}$ occurs.

Source.—The source cavity is made of a material which is chemically inactive at the source temperature and clogging of the aperture by condensation is avoided by running the aperture at a temperature slightly higher than the cavity. The beam material is placed as solid or liquid in the cavity where it produces vapour in equilibrium at the cavity temperature T or, in the case of many gases, it is fed to the cavity from a container outside. Local superheating or discharge tubes are sometimes used to obtain atomic beams by dissociating molecules, and beams containing molecules in excited (metastable) states have been produced by bombarding the molecules leaving the source with low-energy (approximately 10 ev) electrons.

Detectors.—Much of the early work was carried out by condensing the beam on a suitably prepared surface, cooled if necessary, and θ was found from, for example, the optical density of the trace. As a detector, it was insensitive (10 min. to detect 10^{12} molecules/cm.^{2}/sec.) and nonlinear, but it has come back into use with beams of radioactive molecules, for the deposit can then be estimated accurately by normal radioactive counting techniques. The alkali atoms and molecules containing alkali atoms, and most atoms with ionization energies less than 6 ev, can be detected efficiently by allowing them to fall on a hot oxidized tungsten strip. They evaporate as positive ions which are collected on a negatively charged plate connected to a D.C. amplifier. This surface ionization technique is most effective when the ions are accelerated into a sector magnet where ions of one particular mass are selected and then counted by a suitable ion counter. Elimination of unwanted background has allowed the use of alkali beam intensities as low as 10 molecules/cm.^{2}/sec. If the ions are produced by electron bombardment instead of surface ionization, the detector can be used with any beam material, but the efficiency is low (about .01%) unless large electron beams are used, and the mass spectrometer is essential for the elimination of ionized background molecules.

Considerable work has been done with the rare gases and hydrogen using Pirani gauges to measure the small pressure increases (about 10^{-8} mm. mercury) in a cavity when the beam enters through a long channel, but the electron bombardment detector reacts more quickly and yields a better signal-to-noise ratio in spite of its low efficiency.

Typical beam intensities used in practice are 10^{12} molecules/cm.^{2}/sec. or less at detectors 100 cm. from the source.

Gas Kinetics.—Many beam experiments have been carried out to test predictions of gas kinetic theory and study beam scattering by other molecules and surfaces; this gives information about interatomic forces and effective molecular dimensions. The wave nature of a molecular beam was first demonstrated by Stern in 1930 when he scattered helium atoms from the cleavage face of a crystal and observed diffracted beams in the directions predicted by Louis V. de Broglie's theory. Diffraction effects are unimportant in most beam experiments since apertures are never narrower than 10^{-3} cm. and the beam wave length is about 10^{-8} cm.

Light Source.—The spectral line emitted by a well-designed light source has a wave-length spread mainly due to Doppler shifts caused by random motion of the emitting atoms in the line of sight. A. Bogros (1926) showed that such line broadening can be eliminated almost entirely by observing the light emitted perpendicular to a beam of excited atoms, for the velocity spread in the line of sight is then reduced by a factor which is effectively the reciprocal of the beam divergence (in radians), and the line width is reduced in the same ratio. Unfortunately such light sources are weak and they are used only for the most accurate work.

Deflection Experiments.—Stern and W. Gerlach (1921) showed that a beam of atomic silver is split into two distinct beams on passing through an inhomogeneous magnetic field. This is in agreement with the quantum theory of spatial quantization and not with the classical assumption that any orientation of the atomic moment in the field is possible. Deflections proportional to $(\mu_a/v^2)(\partial H/\partial z)$ are produced by the field, μ_a being the atomic magnetic moment and v the velocity, and atoms with moments approximately equal to μ_0, the free electron moment,[1] are easily deflected 0.5 cm. In spite of this, the technique seldom yields an accuracy better than 5% because of the effect of the beam-velocity distribution and the difficulty of estimating large field gradients (10,000 gauss/cm. or more) produced by magnets with curved pole faces.

In weak fields (1,000 gauss or less) the relative arrangement of the nuclear magnetic moment μ_I and electronic moment μ_J are influenced by the field, and μ_a is in general a function of H. At certain critical fields, μ_a becomes zero, and such atoms remain undeflected in the apparatus. Measurement of the resultant peaks in beam intensity yields values for the nuclear spin I, magnetic dipole moment μ_I and electric quadrupole moment Q. This zero-moment technique has now been superseded by the more accurate resonance method.

Proton Moment.—Many atoms and simple molecules like hydrogen have magnetic moments[2] of the order $\mu_{NM} = \mu_0/1{,}836$ because the electron effects cancel leaving only nuclear and rotational moments. In spite of the small deflections which occur in this case, the deflection patterns produced by H_2 molecules were analyzed by O. R. Frisch and Stern in 1933 and the results showed that the proton is not a simple Dirac particle like the electron, because the moment was about $2.5\mu_{NM}$ instead of μ_{NM}.

Resonance Experiments.—According to quantum theory (*see* QUANTUM MECHANICS), the energy levels W_a of a molecule in a field H are discrete and each molecular state has a well-defined magnetic moment μ_a. The magnitudes of W_a and μ_a depend on H, on the electronic structure of the molecule and on the orientations and magnitudes of I, μ and Q for each nucleus in the molecule. Direct measurement of W_a is impossible, but the energy increments $(W_a - W_b)$ when the molecule changes from state a to state b can be deduced by applying a second weak field H_ν, oscillating at frequency ν. Since the transition probability is negligible unless the Bohr resonance condition $h\nu = (W_a - W_b)$ is satisfied, h being Planck's constant, measurement of the resonance condition gives $(W_a - W_b)$.

Molecular Resonances.—I. I. Rabi (1938) and his collaborators detected resonances of this type for the first time using diatomic molecules in the apparatus shown in the figure, and initiated the age of precision measurement of atomic, molecular and nuclear constants. The inhomogeneous deflecting fields A and B, the source slit, collimating slit and detector are adjusted so that beam molecules refocus on the detector when μ_a is the same in the A and B magnets. When H_ν is turned on in the homogeneous C field, transitions associated with nuclear reorientations occur and "flopped" molecules miss the detector because μ_a changes to μ_b (and the deflections due to the A and B magnets fail to cancel). The plot of detector reading against ν shows a typical resonance shape with a minimum at the nuclear Larmor frequency in the C field, $\mu_I H/Ih$ (about 1 kc./gauss). The accuracy with which μ_I can be deduced depends on the field measurement and the sharpness of the resonance. The apparatus contributes part of this line width, the rest being due to the effects of internal fields caused by molecular rotation, vibration and nuclear moments; analysis of the line structure in a high resolution apparatus gives accurate molecular data and nuclear moments. The quadrupole moment of the deuteron was discovered in this way, a result of great importance since it implies that the proton-neutron interaction includes a tensor force.

Atomic Resonances.—Resonances associated with atomic reorientations can also be detected in a similar apparatus at frequencies of about 1 mc./gauss when μ_a is approximately equal to μ_0. These frequencies depend on H_C, the electronic structure

[1]The magnetic moment expected for a Dirac particle with the electron mass and charge is μ_0 (9.3×10^{-21} EMU). It is used as the atomic unit of magnetic moment and is called the Bohr magneton.

[2]The nuclear magneton μ_{NM} is the moment expected for a Dirac particle with the electronic charge and the proton mass. It is used as the unit of nuclear magnetic moment.

of the atom, the electronic contribution μ_J to the atomic movement. and on I, μ_I and Q. Accurate values of these constants can be found by studying the field dependence of such resonances, and also others at frequencies of 100 to 10,000 mc. due to nuclear reorientations in the internal field due to the electrons.

Atomic Clock.—One particular atomic cesium resonance is almost independent of H_C if H_C is less than one gauss, and the frequency in terms of the mean solar year is 9,192.63183 mc. By deriving this frequency from a low frequency oscillator (5 mc.) which is itself controlled by the atomic-beam apparatus, primary frequency standards that are stable and reproduceable to a few parts in 10^{10} have been constructed.

Octupole Moments.—If atomic resonance frequencies are measured with an accuracy of one part in 10^6 or better, it is necessary in some cases to postulate nuclear magnetic octupole moments, as well as quadrupole and dipole moments, in order to account for the experimental results.

Anomalous Electron Moment.—P. Kusch and H. Foley (1948) showed that accurate measurement of μ_J for two states of the same atom allows the electron spin moment contribution to μ_J to be evaluated. They found a value about 0.115% greater than that predicted by Dirac theory, a result which stimulated significant development of the quantum theory of radiation before it was explained satisfactorily.

Lamb Shift.—The Lamb shift in the spectrum of atomic hydrogen is another result of importance in the quantum theory of radiation. W. E. Lamb and R. C. Retherford (1950) bombarded atomic hydrogen with electrons and produced a beam containing metastable $2S_{\frac{1}{2}}$ atoms which survived the passage through the apparatus (10^{-4} sec.) and finally ejected electrons when they fell on a tungsten plate. Other $2P_{\frac{1}{2}}$ atoms produced at the same time decayed immediately (10^{-9} sec.) and failed to eject electrons when they hit the target as ordinary $1S_{\frac{1}{2}}$ hydrogen atoms. According to Dirac theory, the $2P_{\frac{1}{2}}$ and $2S_{\frac{1}{2}}$ states should have the same energy, though optical results indicated a possible separation. This was confirmed by Lamb's experiment, since the $2S_{\frac{1}{2}}$ atoms would have decayed via the $2P_{\frac{1}{2}}$ state if the energy was the same and no electrons would be emitted. Furthermore, by applying a radio-frequency field at about 1,040 mc., $2S_{\frac{1}{2}} - 2P_{\frac{1}{2}}$ transitions were induced and the level separation was measured accurately, the resonance condition being indicated by a fall in electron current at the detector.

Electric Resonance.—Electric moments and other molecular constants have been measured accurately by electric deflection and resonance experiments using apparatus similar to that shown in the figure, but with electric fields instead of magnetic fields.

An important development of this technique is the maser (Microwave Amplification by Stimulated Emission of Radiation) developed by J. P. Gordon, H. J. Zeiger and C. H. Townes (1955). A four-pole electrostatic deflecting field is arranged to focus only ammonia molecules in the upper inversion level through a small aperture into a high Q cavity. If the beam intensity is high enough, stimulated emission exceeds absorption and self-sustained oscillations with frequency stability comparable with the cesium clock result. At lower beam intensities, the device can amplify without adding appreciable noise to the signal. *See* also ELECTRON DIFFRACTION; ELECTRON PARAMAGNETIC RESONANCE.

BIBLIOGRAPHY.—The whole field of molecular beams, both experimental and theoretical, is covered in books by N. F. Ramsey, ***Molecular Beams*** (1956), and by K. F. Smith, ***Molecular Beams*** (1955). Modern techniques and applications are discussed in an excellent review by J. G. King and J. R. Zacharias, *Advanc. Electron.*, 8:1 (1956). Three other reviews, I. Estermann, ***Rev. Mod. Phys.***, 18:300 (1946), J. M. Kellog and S. Millman, ***Rev. Mod. Phys.***, 18:323 (1946), and D. R. Hamilton, *Amer. J. Phys.*, 9:319 (1941), include some of the earlier work. The important principles were first discussed in papers by O. Stern, ***Z. Phys.***, 39:751 (1926), and K. Knauer and O. Stern, ***Z. Phys.***, 39:764 (1926).

(K. F. S.)

ATOMIC BOMB: *see* AIR POWER; ATOMIC ENERGY; NUCLEUS; ROCKETS AND GUIDED MISSILES; THERMONUCLEAR REACTIONS; WORLD WAR II.

ATOMIC ENERGY, a term denoting energy that is released in significant amounts from the atomic nucleus. It is more properly called nuclear energy. (The word "atomic" ordinarily refers only to phenomena involving the orbital electrons of an atom, and not to phenomena involving changes in the atom's nucleus. The term "atomic energy," however, has become so well established in actual usage that it is not likely to be changed.) One method of releasing atomic energy, known as nuclear fission, was first achieved in a controlled manner on Dec. 2, 1942. The same method was used July 16, 1945, in a test explosion of an atomic bomb.

Atomic energy first received public attention on Aug. 6, 1945 when an atomic bomb devastated Hiroshima, Jap. Since that time great improvements have been made not only in powerful atomic weapons but also in the continuous controlled release of atomic energy in devices known as "nuclear reactors." Such reactors are now in operation in many parts of the world.

Another method of releasing nuclear energy is known as nuclear fusion, or thermonuclear fusion. Public announcement was made in 1951 of U.S. atomic bomb tests "contributing to thermonuclear weapons research." By the early 1960s the United States, the United Kingdom and the U.S.S.R. had tested fusion bombs hundreds of times more powerful than fission bombs. Extensive work on controlled thermonuclear reactions was being carried on in these three countries, in the hope that useful power could someday be achieved by this method. (*See* THERMONUCLEAR REACTIONS.)

The energy released in chemical reactions, including TNT explosions, has its origin in the forces which hold atoms together in the form of molecules. It is associated with the outer or electronic structure of the atom. Atomic energy originates from the vastly stronger forces which hold together the particles of the core or nucleus of the atom. The nature of these nuclear forces is not completely understood. They are the subject of much research in an area of science called nuclear physics. Nuclear forces are quite different from electrical, gravitational and magnetic forces. A particle called the pi-meson plays an important role in connection with the forces between nuclear particles, much as the photon does with the electrical forces between charged particles. (*See* NUCLEUS: *Nuclear Structure and Nuclear Forces.*)

Of the two methods of releasing atomic energy, the first is a process which involves spontaneous splitting (fission) of a heavy nucleus into two or more less heavy nuclei. The second process involves the union (fusion) of two light nuclei to form a heavier nucleus. These methods yield comparable amounts of energy per pound of material, vastly more than can be obtained in a chemical reaction. The fission of one pound of uranium yields about 10,000,000 kw.hr. of heat energy. The combustion of 3,000,000 lb. of coal would be required to produce this same amount of energy.

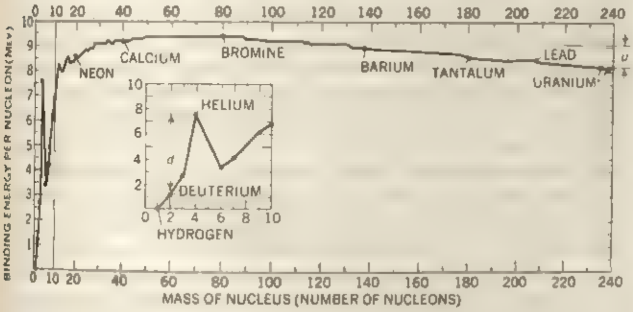
Atomic Structure.—Lord Rutherford (*see* RUTHERFORD, ERNEST RUTHERFORD) first established by theory and experiment that an atom consists of a loose structure of electrons surrounding a heavy central core, the nucleus. It was later discovered that the nucleus consists of positively charged particles called protons and other particles of about the same weight but without charge called neutrons (*see* ATOM; ELECTRON; NEUTRON; PROTON; *see* also PARTICLES, ELEMENTARY). The lightest nucleus, that of ordinary hydrogen, consists of a single proton. One proton and one neutron combined form the nucleus of deuterium, or heavy hydrogen. Heavier nuclei are stable only in certain proportions of neutrons to protons; the ratio is close to 1:1 for light nuclei and increases gradually to about $1\frac{1}{2}$:1 for heavy nuclei.

An atom of an element is identified by the number of protons in its nucleus (atomic number), which is equal to the number of orbital electrons which complete the neutral atom. The number of orbital electrons in turn determines the chemical and most of the physical properties characteristic of the element. Usually a given number of protons can form a stable nucleus with several proportions of neutrons close to the most stable ratio; for example, eight protons combine with 8, 9 or 10 neutrons to form oxygen nuclei of mass 16, 17 and 18, respectively. Such atoms of the same element but of different mass are called isotopes (*see* ISOTOPE). Oxygen nuclei having 6, 7 and 11 neutrons have been formed artificially, but they are unstable and decay by rad-

active disintegration to stable nuclei.

Sources of Nuclear Energy.—When atoms combine in a chemical reaction to form stable molecules, energy is released by a shift in the electron clouds of the original atoms which now must accommodate the added atomic nuclei. In a chemical reaction, the nuclei themselves do not change their composition. Similarly, if protons and neutrons were assembled to form a nucleus of a certain charge and mass, energy would be released in the process. It is known that this must happen, because stable nuclei have a measured mass less than that of the sum of their neutrons and protons. The difference is known as the "mass defect." By using the famous relation between mass and energy first given in 1905 by Albert Einstein (*q.v.*), this mass difference can also be given in terms of energy. Nuclear binding energies thus calculated are millions of times greater than chemical energies. Because nuclear forces are effective only when the particles are extremely close together, and enormous electrostatic repulsive forces must first be overcome, it is unlikely that significant amounts of nuclear energy can ever be released by synthesizing nuclei from protons and neutrons.

The nuclear energy potentially and presently available to mankind results from the fact that some nuclei are bound more tightly than others. The figure shows that the binding energy per nucleon



("nucleon" is a collective name for neutron or proton) is greatest for elements of medium mass, and falls off slightly for both lighter and heavier elements. If a heavy nucleus such as that of uranium of mass 235 is fissioned or split into two parts of comparable mass, both parts will lie in the medium mass range and the total binding energy for the two parts will be higher than it was for the uranium nucleus. The difference in average energy per nucleon ("*u*," in the figure), multiplied by the total number of nucleons in the two atoms, is released in the process.

The combination of two light nuclei to form a heavier one is called fusion. From the inset to the figure it can be seen that formation of the stable helium nucleus (mass 4) from deuterium (mass 2) will release energy ("*d*").

Much smaller amounts of nuclear energy are released by unstable or radioactive elements such as radium, whose nuclei spontaneously change one by one to a more stable form by internal rearrangement. The process is called radioactive decay (*see* RADIOACTIVITY). The first observation of such phenomena was made in 1896 by A. H. Becquerel (*q.v.*) when he observed radiations from certain heavy elements. Rutherford and others in the early years of the 20th century established that these radiations came from the atomic nucleus. As energy sources, these materials were unimportant except for such applications as the use of radium to produce luminous paint for watch dials.

Until 1919 no one had succeeded in producing a nuclear reaction artificially. It did not seem possible to overcome the repulsive force which always exists between two nuclei because of their positive charge. This repulsive force keeps nuclei so far apart that they do not react with one another. A simple mixture of atoms, even at the highest temperatures available on earth, could not be expected to react. Rutherford achieved success by using high-speed helium nuclei (alpha particles) spontaneously ejected from radium. These particles were able to reach the nuclei of nitrogen and knock out protons (nuclei of hydrogen). A nuclear reaction had been produced. It is expressed in a form similar to that used for a chemical reaction:

$$N^{14} + He^{4} \longrightarrow O^{17} + H^{1}$$

In this expression the superscript represents the mass number. Oxygen had been produced from nitrogen and an age-old dream of transmutation of the elements realized. It was the beginning of a new scientific pursuit called atom smashing (*see* ACCELERATORS, PARTICLE).

The Neutron.—Although suggested earlier on the basis of indirect evidence, the neutron was actually discovered in 1932 by Sir James Chadwick (*q.v.*). It was found as a product of the bombardment of beryllium with alpha particles. Its mass was established as nearly the same as that of the proton. This particle, having no electric charge to hinder its penetration into atomic nuclei, proved very effective in producing nuclear reactions, and many such reactions were rapidly discovered. In 1934 Enrico Fermi (*q.v.*) further improved the effectiveness of neutrons in producing reactions by passing them through water or through paraffin. Collisions with the light nuclei in these materials slowed the neutrons and thus gave them more time to react. One especially interesting reaction was produced by Fermi with this method. It was the absorption of slow neutrons by the heaviest element then known, uranium (*q.v.*) of atomic number 92. Radioactivity which suggested the formation of a new element with atomic number 93 was observed. There were also some unexplained results which did not become clear until the discovery of fission four years later.

Uranium Fission.—Prior to 1939 hundreds of nuclear reactions were produced and studied. In many individual cases more energy was received than given, yet there was no serious consideration of nuclear reactions as a practical source of energy. The reason was that large amounts of energy were required to accelerate nuclear projectiles, and even then only about 1 in 1,000,000 reached the target. Even if the product particles emerged with more energy, they had a similarly small chance of producing a second reaction. It appeared impossible to start a nuclear "fire" or to keep it burning. Nature seemed to forbid such a process except in the interiors of stars, where the temperature was sufficiently high and the energy produced did not escape (*see* STAR: *Stellar Structure* and *Stellar Evolution*). The discovery of fission in 1938 provided a new possibility of sustained fire, a chain reaction which would continue to "burn."

At the close of 1938 O. Hahn and F. Strassmann found that barium, a medium-weight element, was one of the products when uranium was bombarded by neutrons. The significance of this discovery was communicated by Lise Meitner and O. R. Frisch, refugees from Germany then working in Copenhagen, to Niels Bohr (*q.v.*), who was preparing to visit the U.S. Arriving in Jan. 1939, Bohr discussed the Hahn and Strassman discovery with Einstein, J. A. Wheeler and others. The presence of barium meant that uranium had been split into two nearly equal fragments, which represented a tremendous jump in energy produced over all previous transmutation reactions. Calculations showed that such a reaction should yield 10 to 100 times the energy of less violent nuclear disintegrations. This was quickly confirmed by experiment.

Bohr and Fermi discussed this reaction, called "fission," at a conference in Washington, D.C., on Jan. 26, 1939, and Fermi made the suggestion that neutrons might be released in the process. If this were the case, and if the number of neutrons was more than one, some losses could be tolerated and still leave a neutron to initiate another fission of uranium, thus producing a chain reaction which would continue to "burn" uranium. This suggestion produced considerable excitement, and physicists present at the conference initiated calls to their laboratories to start the search for fission neutrons. They were found, about $2\frac{1}{2}$ per fission on the average, though the number was kept secret during World War II.

Fission Reactions.—Theoretical studies by Bohr and Wheeler suggested that the fission observed with uranium did not come from the more abundant U^{238} variety but from U^{235}, an isotope which constituted only 1 part in 140 of natural uranium. By using minute quantities of uranium somewhat richer in U^{235} than normal, this prediction was confirmed. It was also found that neutron

is still an essentially limitless supply of fission reactor fuel available. H. Brown and L. T. Silver have shown that the granite rocks which make up most of the earth's crust contain about 15 g. per ton of uranium and thorium. Of this, about 3 g. per ton can be easily extracted by crushing the granite and leaching it with acids. Such fuels would cost more than those now obtained from high grade ores, but still the total energy expended in quarrying the rock and recovering the uranium and thorium would be only a negligible fraction of the yield in fission. A ton of granite can thus yield about nine times the energy of a ton of coal. The uranium and thorium would have to be converted to fissionable form in a special type of nuclear reactor known as a breeder reactor. Such reactors have been built and operated and proved technically feasible.

Thus the fears of the past over exhaustion of energy supplies can now be allayed, because both the rocks and the seas have energy content sufficient to last mankind for 10,000,000,000 years, which is about as long as the solar system is expected to last.

Nuclear Reactors.—A nuclear reactor, or atomic reactor, is a device containing fissionable or fusionable material in sufficient amount and so arranged that the device is capable of initiating and maintaining a controlled, self-sustaining nuclear chain reaction. Nuclear reactors were formerly called "piles," but the latter term is now virtually obsolete.

Fusion Reactors.—Nature has its own very successful version of a fusion reactor, namely, a star. Man's attempts to produce a controlled, continuous fusion reactor have so far served more to indicate the difficulties than to produce a solution. From the experiments that had been conducted by the early 1960s, it was generally believed that a fusion reactor would have to be a tremendous machine with heavy shielding, huge vacuum pumps, coils, and magnets to form a magnetic container for the hot gases. (The temperature necessary for fusion to occur is so high that the atoms are fully ionized, that is, all the electrons are separated from their orbits around the atomic nuclei, and the mixture of rapidly moving nuclei and electrons form an electrically neutral gas called a plasma. The only feasible container for a plasma appeared to be a strong magnetic field in a vacuum.)

Fission Reactors.—By the early 1960s the number of fission reactors operating in the world was well over a hundred. These reactors, constructed for a wide variety of applications, varied in core size from a few inches to dozens of feet, and in power from a few watts to hundreds of megawatts. A few of these applications will be discussed to indicate the importance of fission reactors. All reactors produce neutrons, gamma rays, fission products and heat. In most applications use is made of only one of these products.

1. Neutron sources. Compared to previous sources of neutrons for experimental purposes, reactors provide tremendously larger numbers of neutrons at moderate cost. Reactors have thus become important tools in physics research and in engineering development. Isotope production, including plutonium production, is another important use of a reactor as a neutron source. Hundreds of different radioactive species, having thousands of important applications, are produced. For example, radioactive cobalt has nearly displaced radium for gamma-ray therapy, radiography and other uses. (*See* RADIOACTIVITY.)

2. Gamma-ray sources. The action of the gamma radiation (high-frequency electromagnetic radiation) produced by reactors is generally destructive, a fact which requires heavy shields around the chain-reacting core. At least two beneficial uses of this radiation have been found, however—sterilization of foods and strengthening of plastics. Radiation sterilization allows plastic-wrapped meat, for example, to be kept for months without refrigeration. In the case of plastics, bombardment of polyethylene and other polymers produces cross-linking, or formation of additional chemical bonds which tie together laterally the end-to-end strands formed by the normal polymerization. Since the amount of cross-linking can be controlled by the radiation exposure, the properties of the plastic can be varied at will from those of a soft material which sags in warm water to those of a tough resilient solid.

3. Process heat. The principal release of energy in a reactor starts with the fission fragments, which fly apart with energies corresponding to temperatures of millions of degrees. The reactor is theoretically capable of operating at any temperature which the fuel and structure can withstand, subject to the practical limitation that it must be possible to extract the heat in a useful form. Some industrial or process heat applications for which reactors are potentially suitable are, in descending order of temperatures: fixation of atmospheric nitrogen to form nitrate fertilizer, conversion of coal to form petroleum products and gaseous fuel, distillation of sea water and heating of buildings.

4. Propulsion reactors. The chief advantage of a reactor for vehicle propulsion is the extended range given the vehicle. A few pounds of uranium (U^{235}) or plutonium form a fuel supply capable of driving the largest ship around the world. By the early 1960s the U.S. navy had over 20 nuclear submarines afloat, and was rapidly building a nuclear navy. The U.S.S.R. was operating a nuclear-powered icebreaker, the "Lenin," and the first nuclear-powered merchant ship, the NS "Savannah," had been launched.

Two types of nuclear aircraft were under development in the U.S. in the same period, a ramjet and a turbojet, but neither had undergone flight tests. Various types of nuclear-powered surface vehicles had been proposed, ranging from giant tractors to railroad locomotives.

The potential advantages of nuclear propulsion over propulsion by chemical fuels are most marked in the case of space rockets, and the advantage increases rapidly as larger payloads and longer ranges are sought.

5. Electric power. Power reactors, like process heat reactors or steam boilers, are primarily sources of heat. The heat is transferred to a working fluid such as steam or gas, and partially converted to mechanical energy by a turbine. The possibility of direct conversion without moving parts through the use of thermionic converters or thermoelectric devices was receiving increasing attention in 1960 (*see* ENERGY CONVERSION, DIRECT).

The first reactor to produce useful electric power was the Experimental Breeder Reactor No. 1, built by the Argonne National laboratory in 1951. The first experimental power station of the U.S.S.R. began operating in May 1954, and the first large-scale reactor power plant to operate (May 1956) was the United Kingdom's Calder Hall station. None of these plants produced power as cheaply as large coal-fired plants, but they were expected to lead the way to larger, improved reactor plants that could compete with coal. Most countries were anxious to gain experience with the new source of energy, even though a clear-cut cost advantage had not been attained. Experience with the largest stations showed that construction and operating costs were reasonable, and that the biggest remaining obstacle to achieving economic nuclear power was in fuel cycle cost.

The basic cost of the fuel itself in terms of energy content is in the same range as coal, but a reactor cannot consume all the fissionable material in its fuel at one loading. To operate at all, it must always have present at least a sufficient number of fissionable atoms to sustain the chain reaction. This amount of material is called the critical mass. It varies with the concentrations of fissionable atoms, the kinds of other atoms present, and the configuration of the system. After a certain fraction of the original fuel is consumed the fuel must be replaced. This may be due to depletion of the fissionable material or to accumulation of the fission-product atoms, which can absorb the neutrons needed for the chain reaction and can in some cases cause destructive structural changes in the fuel material. The discharged fuel is highly radioactive and must be handled by machinery inside enclosures shielded by heavy concrete walls or by thick layers (about 15 ft.) of water. The valuable fissionable portion of the fuel structure must be recovered and used to manufacture new fuel structures, called fuel elements, that can undergo another trip through the reactor. The operations of handling and recovering the discharged fuel and remanufacturing the new fuel are known as fuel reprocessing, and are quite costly. Extensive effort has been expended in searching for cheaper ways to produce fuel elements which would last longer in the reactor and be easier to reprocess.

By the early 1960s three general groups of reactors, all having certain advantages and disadvantages, had emerged:

1. Water-cooled reactors. In these the water serves as the neutron-slowing medium as well as the coolant. As an outgrowth of the submarine program, these reactors enjoy an advanced state of development. Compared to the other two groups, water reactors are characterized by high operating pressure and low operating temperature. If heavy water (D_2O) is used as the coolant, water-cooled reactors can be fueled with natural uranium metal, which contains only 0.7% of U^{235}. Usually, uranium oxide fuels are used when ordinary water is the coolant, necessitating fuel enrichment with extra U^{235} from diffusion plants. One form of water reactor uses a homogeneous solution of enriched fuel in heavy water. When the reactor core is surrounded by a so-called blanket containing mostly thorium, the neutrons leaking from the core are captured in the thorium, converting some of the thorium to fissionable U^{233}. Such a reactor can "breed" as much fuel in its blanket as it burns in the core.

2. Gas-cooled reactors. These reactors, exemplified by the large British nuclear power stations, can also be fueled with natural uranium. The neutrons are slowed down (moderated) by graphite. The more advanced types use enriched fuel and are being designed for higher and higher temperatures. The gas coolant has been used to produce steam in a separate unit, but in principle the gas could drive a gas turbine directly.

3. Sodium-cooled reactors. Although the art of handling molten sodium metal has not been highly developed, sodium is attractive as a reactor coolant because of its excellent heat transfer capability at high temperatures without the need of a pressure vessel. Although sodium reacts with air and water, when properly enclosed and purified it is less corrosive than water. The fast-neutron breeder reactor is potentially the most attractive of the sodium-cooled types. For this type no neutron-slowing medium is used, and fissions are produced by fast neutrons. If the fuel used is plutonium, and the core is surrounded by a blanket of ordinary uranium, such a reactor will breed as much as 50% more plutonium than it consumes.

For more detailed information on fission reactors, *see* NUCLEAR ENGINEERING.

(R. P. HA.)

ATOMIC NUMBER, the number of a chemical element in the periodic system. In this system, the elements are arranged according to the number of nuclear protons or extranuclear electrons in an atom. For experimental basis *see* ATOM; NUCLEUS; PERIODIC LAW; VALENCE.

ATOMIC WARFARE, a term that came into use after the first employment of atomic bombs against Japan at the end of World War II. Simply stated, it is warfare in which atomic weapons are used. Such weapons may take the form of atomic missiles or rockets (both large and small, short-range and long-range), atomic bombs dropped from aircraft, artillery shells carrying atomic warheads, or atomic land mines. All-out atomic war threatens sudden and catastrophic destruction followed by long-term danger from lingering radioactivity.

See AIR POWER; ARMY; ATOMIC ENERGY: *The Atomic Bomb*; ROCKETS AND GUIDED MISSILES; TACTICS: *World War II* and *Nuclear Age*.

ATOMIC WEIGHT, a number, different for each chemical element, that gives the weight or mass of an atom of the element relative to that of an atom of an element taken as a reference standard. From 1900 until 1961 oxygen was used as the reference element for the so-called "chemical scale" of atomic weights, with an assigned atomic weight of 16. This number was derived from the approximate atomic weight of oxygen on an earlier scale, for which hydrogen, with atomic weight 1, was the reference standard. Because of this circumstance, the atomic weights of nuclides coincide, to the nearest integer, with their mass numbers. A mass number represents the total number of nucleons (protons and neutrons) in the nucleus of an atom (*see* ATOM: *Atomic Structure and Periodic System*). In 1961 the principal isotope of carbon, carbon-12, replaced oxygen as the reference standard, changing the then-established atomic weights very slightly (about 0.004%).

In the following discussion the terms "atomic weight" and "atomic mass" are essentially synonymous. "Atomic mass" describes more accurately the property of matter that is of basic interest. However, the term "atomic weight" has the sanction of long usage and is valid when measurements are based upon weighing.

SCALES

In 1929, it was discovered that natural oxygen contains small amounts of two slightly heavier isotopes, in addition to the most abundant isotope mentioned above. Thus it became apparent that the number 16, as used in the chemical scale of atomic weights, represented the average weight of the atoms of the three isotopic species of oxygen as they occur in nature.

It is possible by several methods to determine the relative weights (or masses) of the atoms of individual isotopic species of the elements. This led to the adoption of a scale of atomic weights in which 16 is the numerical value assigned to the atoms of the predominant isotope of oxygen. This scale was known as the physical scale. Because natural oxygen contains only minute amounts of the other two isotopes, the two scales differed only slightly. They were numerically related to each other in the approximate ratio 1:1.000275.

Because this ratio could not be fixed exactly, owing to slight variations in the isotopic composition of natural oxygen from different sources, and because of the difference between the scales, chemists and physicists in 1961 established a new scale which replaced the two then in use. The most abundant isotope of carbon, with an assigned relative weight (mass) of 12, was chosen as the reference species for this new scale. This scale required only minimal changes in the values that had been used for chemical atomic weights, lowering them by 43 parts in 1,000,000. Values based on the physical scale were lowered by 318 parts in 1,000,000.

EXPERIMENTAL DETERMINATION

Although numerous discoveries concerning the structure and composition of atoms and the transformations that atoms can undergo have made necessary substantial modifications in atomic theory, the concepts of atoms and atomic weights are still fundamental and of great usefulness. The vast majority of changes that occur in the composition of matter are those in which the atoms themselves are not altered. This class of changes, termed chemical, can be readily distinguished from those changes, termed nuclear, in which atoms are altered, by a simple classification based upon the magnitude of the energy consumed or expended in the change. The least energetic nuclear reaction involves an exchange of energy more than 1,000 times greater than that involved in the most energetic chemical reaction. (*See* ATOMIC ENERGY; NUCLEUS: *Nuclear Reactions*.)

In chemical reactions all quantitative operations, whether aimed at the analysis or the synthesis of materials, pivot on atomic and molecular weight. (The molecular weight of a molecule is numerically equal to the sum of the atomic weights of all the atoms which make up the molecule; *see* MOLECULE.) The numbers representing these weights determine the accuracy of the operation of the most basic law of chemistry—that of definite combining proportions (*see* ATOM: *Dalton's Theory*). Ever since this law was discovered (Joseph Louis Proust, 1799; John Dalton, 1808), one of the most important tasks of the chemist has been to determine atomic weights. In the 19th century this activity marked the transition of chemistry from a purely descriptive to a quantitative science. In the 20th century the goal of both chemists and physicists has been to achieve ever-increasing accuracy in the measurement of these weights.

Chemical Methods.—Of the various methods available for the determination of atomic weights, the first to be used is based upon converting a precisely weighed quantity of the unknown element (or of a compound of the unknown element and another element of known atomic weight) into a resultant compound which

contains some other element whose atomic weight is known; the resultant compound is then weighed. Until about 1930 this was the most generally applicable method. If all substances are of the requisite purity, and no loss has occurred during the conversion, the unknown atomic weight is derived from the ratio of the two measured weights by a simple proportion. An illustration can be drawn from the determination of the atomic weight of iron by G. P. Baxter and C. R. Hoover. These investigators treated weighed quantities of ferric oxide (Fe_2O_3) with hydrogen at a high temperature and thus converted the meticulously prepared oxide to pure iron. The loss in weight represented the quantity of oxygen present in the oxide. In a typical experiment the two observed weights were 7.59712 g. and 5.31364 g. and the loss 2.28348 g. From the proportion $(2.28348):(5.31364) = O_3:Fe_2 = 3(16.000):2x$, the atomic weight of iron, x, was found to be 55.848. Numerous repetitions of the experiment minimized the effect of errors.

Another type of reaction that has been much used is one in which the chlorine or bromine combined with an element whose atomic weight is to be determined is caused to combine quantitatively with silver. For this purpose the combining weights of silver with chlorine and with bromine must be known and one or more of these three elements must be numerically related to oxygen. T. W. Richards, Baxter and their associates performed many experiments in which weighed amounts of the most carefully prepared metallic silver were converted, without significant loss or contamination, into silver nitrate ($AgNO_3$), silver chloride ($AgCl$) and silver bromide ($AgBr$). In the first of these conversions knowledge of the atomic weight of nitrogen derived from another chemical ratio permitted the establishment of a ratio relating silver to oxygen and thus yielded the atomic weight of silver. With this intermediate but carefully determined value, the ratios Ag:AgCl and Ag:AgBr yielded the atomic weights of chlorine and bromine. With the values for silver, chlorine and bromine thus fixed, use of the reaction mentioned above made it possible to determine the atomic weights of many elements that form chlorides and bromides.

Another, and closely related, procedure is illustrated by the work of Baxter and A. H. Hale, who determined the chemical equivalence (*see* EQUIVALENT) of sodium carbonate (Na_2CO_3) and iodine pentoxide (I_2O_5) by dissolving in water weighed amounts of these two compounds. Since sodium carbonate is a base and a solution of iodine pentoxide is a strong acid, observations of the relative weights of the two required to yield a precisely neutral solution provided the measure of their chemical equivalence. It is to be noted that three elements, sodium, carbon and iodine, are involved in addition to the former reference element, oxygen. If the atomic weights of any two of the three are known from other work, the value of the third can be determined. The work cited was aimed at the determination of the atomic weight of carbon, but the result obtained was not highly accurate because of errors in the assumed values for sodium and iodine. Later recalculation showed that the experimental work was of very high accuracy.

During the 19th century extensive investigations involving chemical ratios were made by J. Berzelius, J. C. G. de Marignac, J. B. A. Dumas, J. S. Stas and many others. To the later investigators that have been mentioned already, all of whom worked in the United States, should be added B. Braumer and O. Hönigschmid as leaders in this field in Europe.

Physical Methods.—The most important physical methods of determining atomic weights involve the use of gas density ratios, X-ray diffraction, mass spectroscopy, nuclear reaction calculations, and microwave spectroscopy.

Gas Density Ratios.—A general method of determining atomic weights, but one that is applicable only to gases, depends upon Avogadro's rule (the assumption that under identical physical conditions equal volumes of gases contain the same number of molecules) and consists essentially of weighing like volumes of different gases under like conditions of temperature and pressure. The ratio of the densities (mass per unit volume) of two gases, when suitably corrected for the slight deviations of each gas from the behaviour of a so-called "perfect" gas, is equal to the ratio of their molecular weights. If the molecular composition is known from other considerations, atomic weights are readily derived, and if one of the gases is oxygen, the atomic weight in question is related directly to oxygen. The method involves the same requirements as the chemical methods with respect to the purity of the substances under consideration, but involves greater difficulties with respect to weighing and the additional problems of accurate control of temperature and pressure. The method was at first the only one applicable to the six inert gases (helium, etc.), and it also contributed to the study of other elements. Noteworthy investigations involving the gas-density method were made by Lord Rayleigh, E. W. Morley, P. A. Guye, A. Leduc, E. Moles, R. Whytlaw-Gray and Baxter.

X-Ray Diffraction in Crystals.—A second method based upon purely physical measurements, but involving solids rather than gases, has been used to a limited extent. It is possible to determine from X-ray diffraction measurements the geometrical arrangement of atoms and the distances between atoms in a crystalline substance (*see* CRYSTALLOGRAPHY: *Diffraction by Crystals*). From these data can be computed the actual volume occupied by the small number of atoms or combinations of atoms that form the basic pattern of the crystal, the so-called unit cell, and thus, by a simple proportion, the volume occupied by any multiple of that number, for example one based upon Avogadro's number (6.023 $\times 10^{23}$); that is, the number of molecules contained in a gram-molecular weight of a substance (*see* AVOGADRO'S CONSTANT). The volume thus computed will be that occupied by a gram-molecular weight of the substance in question. By means of the relation between weight and volume of the substance, the weight of the gram molecule is derived from this volume. This weight is numerically identical to the molecular weight, from which the atomic weights of the constituent elements can be obtained. If the molecular weight of a crystalline substance is already known, the method offers a valuable means of determining Avogadro's number. The method places the same demands of purity on the substance used as do other methods, and, in addition, requires that the crystals be free of imperfections within the limits of the desired accuracy.

Mass Spectroscopy.—A purely physical method that came into increasingly general use after about 1920 (F. W. Aston, J. Mattauch, K. T. Bainbridge, A. O. C. Nier) is that which determines the mass (or rather the ratio of mass to electric charge) of rapidly moving charged atoms or molecules by means of their deflection by electric and magnetic fields. This technique is known as mass spectroscopy (*q.v.*). The positions of impact of beams of such charged particles on a photographic plate or sensitive electrical receiver determine the relative masses of the particles among a selected group. In its original form (J. J. Thomson, 1912) the method furnished the first experimental evidence not only that all atoms of some elements are alike in mass but also that all atoms of certain other elements are not of equal mass.

At most, 22 of the substances recognized as chemical elements are known to exist in nature in simple (nonisotopic) form. Some elements have numerous natural isotopes; for example, ten natural isotopes of tin and nine of xenon are known. When atomic weights are determined by mass spectroscopy, it is necessary to measure not only the relative masses of the several isotopes but also their relative abundances. Relative abundances of isotopes cannot be determined as accurately as individual masses, but continuing improvements in this type of measurement have resulted in the adoption of values for a number of atomic weights to replace demonstrably less accurate values derived from chemical methods and gas-density determinations.

Calculations from Nuclear Reactions.—In many instances masses of individual nuclear species (nuclides) can be calculated with high precision from the net energy change ΔE involved in a nuclear reaction in which one element is transformed into another. The change in mass, Δm, is computed by means of the Einstein equation $\Delta E = \Delta m \cdot c^2$ for the equivalence of mass and energy, c being the velocity of light. The accuracy of the mass determination by this method is equal to and possibly greater than that afforded by the most advanced mass-spectroscopic measurements. For an element having several isotopes, however, it is necessary to supplement the mass measurements with isotopic abundance

measurements in order to derive the atomic weight.

Microwave Spectroscopy.—Displacements between the rotational spectra of molecules are a function of the molecular masses and hence, for similar molecules, may yield information on the masses of specific atoms in the molecules. Because of the limitation imposed by the required similarity of the molecules, this technique is applicable principally to comparing the masses of isotopes. The accuracy of the method is considerably less than that of mass spectroscopy or nuclear reaction calculations. (*See* MOLECULAR SPECTRA.)

TABULATED VALUES

Although atomic weight was once regarded as a unique, unalterable property of an element, the processes of both natural and artificial nuclear transformations and of isotopic differentiation make it possible for almost every element to vary in its isotopic composition and thus to have a variable atomic weight. Thus, knowledge of the atomic weight of an element must be accompanied by a knowledge of its isotopic composition. However, the vast majority of chemical operations for which a knowledge of atomic weights is required involves elements in a state of essentially constant isotopic composition. It is only to such elements that the term "atomic weight" can be applied with its traditional meaning and usefulness. It is therefore recommended that the term, when used without qualification, be limited to elements as they exist in nature without artificial alteration of their isotopic composition and, further, to natural elements whose isotopic composition is essentially unaffected by the several phenomena of radioactivity. In keeping with this recommendation, the accompanying table of weights lists no values for the radioactive elements with the exceptions of thorium and uranium, whose isotopic compositions in nature are essentially constant. For certain stable elements, such as lead, whose isotopic compositions are affected by radioactivity, the value given is for the isotopic composition that has not been so affected. (*See* RADIOACTIVITY.)

Variations have been observed in the isotopic compositions of a number of the elements in their natural occurrences, and such variations must be considered possible for any element having isotopes. The atomic weights of six elements are known to be affected within the limits of their assigned values. The magnitudes of these effects are stated in a footnote to the table. A second footnote indicates the estimated experimental uncertainties of the atomic weights of five elements. (ED. WS.)

International Atomic Weights

*The atomic weight varies because of natural variations in the isotopic composition of the element. The observed ranges are boron, ±0.003; carbon, ±0.00005; hydrogen, ±0.00001; oxygen, ±0.0001; silicon, ±0.001; sulfur, ±0.002. †The atomic weight is believed to have an experimental uncertainty of the following magnitude: bromine, ±0.002; chlorine, ±0.001; chromium, ±0.001; iron, ±0.003; silver, ±0.003. For other elements the last digit given is believed to be reliable to ±0.5.

ATOMISM, in philosophy, is the doctrine that the material universe is composed of simple and unchangeable minute particles called atoms (Gr. *atoma*, "things that cannot be cut or divided"). It holds that all observable changes must be reduced to changes in the configuration of atoms and that the multiplicity of visible forms in nature is likewise based on differences of configuration.

In order to understand the historical development of atomism and, especially, its relation with modern atomic theory, it is necessary to distinguish between atomism in the strict sense and other forms of atomism. Atomism in the strict sense, as propounded by the Greek philosophers Leucippus and Democritus (*qq.v.*) in the 5th century B.C., should be regarded as an attempt to reconcile with the data of sense experience the thesis of Parmenides (*q.v.*) that matter is unchangeable. Parmenides rejected the possibility of change on rational grounds: change seemed to him to be unintelligible. Democritus agreed with Parmenides on the unintelligibility and impossibility of qualitative change, but did not agree with him on the impossibility of quantitative change. This type of change, he maintained, is subject to mathematical reasoning and therefore possible. By the same token, Democritus denied the qualitative multiplicity of visible forms, but accepted a multiplicity based on purely quantitative differences. Consequently, the only differences between atoms, according to Democritus, must consist in their size and figure. The infinite variety of observable things could be explained by the different shapes and sizes of the atoms which constituted them and by the different ways in which the atoms were combined. Observable changes were based on a change in combinations of the atoms. During such combinations or separations, however, the atoms themselves remained intrinsically unchanged.

Other forms of atomism differed from that conceived by Democritus mainly in two points. First, some atomists did not restrict the differences between the atoms to purely quantitative ones, but accepted also differences in quality. The system of Anaxagoras (*q.v.*) even assumed as many qualitatively different atoms as there are different observable primitive substances, but usually only a few kinds of atoms were assumed, based on

the doctrine of the four elements, earth, water, air and fire, as for instance in the system of Empedocles (*q.v.*). Secondly, some atomists regarded "atoms" as divisible, whereas Democritus had regarded them as indivisible. This conception that "atoms" can be divided occurs frequently, but is usually accompanied by the view that they then become "atoms" of another substance. Here again, however, an exception must be made in the case of Anaxagoras, who held that "atoms" can be divided, but remain of the same kind (hence they were described as "homoiomeric," that is, possessing similar parts).

From the historical viewpoint, the most important system admitting qualitatively different atoms is that developed by certain commentators of Aristotle, namely Alexander of Aphrodisias (2nd century A.D.), Themistius (4th century A.D.) and Philoponus (6th century A.D.). In their system the atoms are called *elachista* ("very small" or "smallest"), the Greek equivalent of the Latin *minima*, the word used in medieval Latin writings to indicate the smallest particles.

In Greek philosophy there were also transitions between qualitative and quantitative forms of atomism. Plato characterized the atoms of the four elements by different mathematical forms.

Examples of qualitative atomism, based upon the doctrine of the four elements, are also found in Indian philosophy. In some Indian systems the atoms are not absolutely indivisible, but only relatively so. In certain aspects Indian atomism is, therefore, more related to the *minima* doctrine than to the atomism of Democritus. On the other hand, in Indian atomism the atoms cannot be destroyed, and that is a more Democritean than Aristotelian characteristic.

In evaluating the importance of Greek atomism in the light of modern atomic theories, it should be borne in mind that in Greek thought philosophy and science still formed a unity. Greek atomism, then, was inspired as much by the desire to find a solution for the problems of mutability and plurality in nature as by the desire to provide scientific explanations for specific phenomena. While it is true that some of the Greek atomists' ideas can rightly be considered as precursors of later physics, the main importance of the old atomistic doctrine for modern science does not lie in these primitive scientific anticipations. Much more important is the attempt to reconcile with the variety and mutability discerned by sense experience the thesis of Parmenides about the unity and the immutability of matter. In its search for universal and unchangeable laws, modern science is to a great extent inspired by the same idea as Parmenides, since universal laws presuppose a certain unity in the material world, and unchangeable laws cannot be established without the presupposition that something unchangeable must be hidden behind all changes. The great achievement of the Greek atomists, therefore, was that they took a general view of nature as a whole, which made a scientific attitude possible. To this both the quantitative and the qualitative atomism contributed, the former by drawing attention to the mathematical aspects of the problem, the latter by drawing attention to the empirical.

A few words may be added concerning the later history of atomism. The influence of Aristotle precluded Democritus' atomism from gaining pre-eminence in ancient Greek thought, though there were a few adherents of Democritean atomism in later times, such as Epicurus and the Roman poet Lucretius (*qq.v.*). Even so, the general idea of atomism had a certain influence in the long period intervening between its exposition by Democritus and the revival of it by Pierre Gassendi (*q.v.*) in the 17th century. During this period the *minima* doctrine was elaborated from an abstract philosophical doctrine in such a way that it could be used in science. This is largely due to the influence of the Arabic philosophers in the middle ages, especially Averroës (*q.v.*) and his followers in the Christian west. Inspired by the writings of the Arabs, medieval Europe became interested not only in philosophy but also in science. Accordingly the emphasis in atomistic thinking came to be shifted from the philosophic to the scientific, and attention was focused no longer on the general problem of how to explain mutability in nature, but on trying to explain concrete changes. Thus, in the 16th and 17th centuries, "atomists" such as Julius Caesar Scaliger (1484–1558), Daniel Sennert (1572–1637), David van Goorle (1591–1612), Gassendi (1592–1655) and Robert Boyle (1627–91) were blending together the typical Democritean approach and the Aristotelian into a general corpuscular theory which prepared the way for the atomic theory of John Dalton.

See K. Lasswitz, *Geschichte der Atomistik vom Mittelalter bis Newton*, 2 vol., 2nd ed. (1926); A. G. M. van Melsen, *From Atomos to Atom*, 2nd ed. (1960). (A. G. v. M.)

ATONALITY, a term loosely used to describe a concept of harmony (*q.v.*). Introduced by Arnold Schoenberg (*q.v.*) as a result of the increasing chromaticism in traditional harmony, and illustrated in his own transitional works (1908–11), atonal harmony, which he preferred to call "pantonal," eliminated the tonal centre and with it the concept of key. The 12 semitones of the diatonic scale were thus melodically and harmonically unrelated to each other. Paul Hindemith, Anton Bauer, Herbert Eimert and Darius Milhaud also adopted this principle. Schoenberg soon abandoned atonality for the 12-note system, though atonal works continued to be written by other composers.

See H. Eimert, *Atonale Musiklehre* (1924).

ATONEMENT, one of the perennial themes in the history of religion and of theology. Rituals of expiation and satisfaction appear in most religions, whether primitive or developed, as means by which the religious person re-establishes or strengthens his relation to the Holy. Atonement is often attached to sacrifice (*q.v.*) and, like sacrifice, tends to connect ritual cleanness with moral purity and religious acceptability. In Christian theology the term "atonement," as an early translation of "reconciliation" in II Cor. v, 18–19, has been a favourite way of speaking about the saving significance attributed to the death of Jesus Christ on the cross. Various theories of the atonement have arisen: satisfaction for the sins of the world; redemption from the devil or from the wrath of God; a saving example of true suffering love; the prime illustration of divine mercy; a divine victory over the forces of evil. One or another of these images has tended to predominate in the system of a theologian, but most theologians and most eras in the history of the Christian church have usually spoken of the work of Christ in many different metaphors rather than in only one. Christian theories of atonement are discussed at greater length in the article JESUS CHRIST.

ATONEMENT, DAY OF: *see* JEWISH HOLIDAYS.

ATRATO, a river of western Colombia, South America, rising on the slopes of the western cordilleras, in latitude 5° 36′ N. and flowing almost due north to the Gulf of Urabá, or Darién, where it forms a large delta. Its length is 416 mi., but because of the heavy rainfall of this region it discharges no less than 175,000 cu.ft. of water per second, together with a very large quantity of sediment, which is rapidly filling the gulf. The river is navigable to Quibdó (250 mi.). The Atrato at one time was considered as a feasible route for a transisthmian canal. (Js. J. P.)

ATREK (Persian RUD-E ATRAK), a river which rises in latitude 37° 10′ N., longitude 59° E. in the Kuran Dagh, a mountain range in the northeastern part of the Iranian province of Khurasan. It flows westward, forming for a part of its course the international boundary between Iran and the Turkmen Soviet Socialist Republic U.S.S.R. It is 311 mi. long. It empties into the southeastern corner of the Caspian sea, its mouth being on the Soviet side of the frontier near the Iranian port of Bandar Shah. It is used for irrigation and, like other rivers flowing into the Caspian, its lower course is a spawning ground for sturgeon, a source of caviar. (D. D. Cr.)

ATREUS, in Greek legend, son of Pelops and Hippodamia, elder brother of Thyestes and king of Mycenae. The story of this family—"the house of Atreus"—is virtually unrivaled in antiquity for complexity and corruption. After their father was cursed by Myrtilus (*see* PELOPS), the brothers began their bloody course with the murder of their stepbrother, Chrysippus. The favourite of his father (and born of a nymph, not of Hippodamia), Chrysippus apparently was to inherit the kingship. Atreus

Thyestes and Alcathous (*q.v.*), conspiring with their mother against him, threw him into a well where he drowned.

The brothers were compelled to flee their native city of Pisa, Alcathous to Megara, the others to Mycenae, where Atreus became king on the death of Eurystheus. But Thyestes either contested Atreus' right to rule (in some versions by stealing the golden sheep that was the symbol of kingship), or seduced Atreus' wife, Aërope; in consequence he was driven from Mycenae. To avenge himself, Thyestes sent Pleisthenes (Atreus' son, whom Thyestes had brought up as his own) to kill Atreus, but the boy was himself slain, unrecognized by his father.

Later, when Atreus had learned the truth, he recalled Thyestes to Mycenae, in apparent reconciliation, and feasted him on the flesh of his son (or sons), whom Atreus had slain in vengeance for the death of Pleisthenes. Thyestes fled in horror, coming to Sicyon, where he impregnated his own daughter, Pelopia, in the hope of raising one more son to avenge himself. Atreus subsequently married Pelopia, without knowing who she was or that she was pregnant; she bore Aegisthus, the son of Thyestes but believed by Atreus to be his own.

Still later, Thyestes was found by Agamemnon and Menelaus (sons of Atreus and Aërope) and imprisoned at Mycenae. Aegisthus being sent to murder Thyestes, mutual recognition took place via the sword that Pelopia had taken from her father and given to her son. Father and son slew Atreus, seized the throne and drove Agamemnon and Menelaus out of the country (for their further adventures *see* the respective articles).

The artificial complexity of the myth is clear from the thematic repetition of incidents in the two branches of the family: just as

HOUSE OF ATREUS

nymph = Pelops = Hippodamia

Chrysippus Aërope = ATREUS = Pelopia Thyestes Alcathous

Pleisthenes Helen = Menelaus son(s) Pelopia Aegisthus
Clytemnestra = Agamemnon

Aegisthus was born of his father and sister, so Agamemnon was said to have been the son of Aërope and his own brother Pleisthenes. The attempted murder of Atreus by his son Pleisthenes, depending from the lack of recognition between the two, is mirrored in the attempt by Aegisthus unknowingly against his father Thyestes. Similarly, the same kind of incident repeats itself in time, the repeated corruption in the family being a feature that particularly attracted Aeschylus to the myth (*Oresteia*): as Thyestes seduced Aërope, so his son Aegisthus seduced Clytemnestra. As Atreus was slain for the possession of the throne of Mycenae by Thyestes, so Agamemnon was slain by Aegisthus (in Homer) for the same reason. (T. V. B.)

ATRI, a city of central Italy, region of Abruzzi e Molise, province of Teramo, stands on a hill, 1,450 ft. above sea level, overlooking the Adriatic (7.5 mi. [12 km.] away) on one side and the Gran Sasso on the other. Pop. (1961) 12,469 (commune). The 13th-century cathedral has a Romanesque façade, a series of frescoes by Andrea Delitio (15th century) and archives including illuminated manuscripts, three of which were printed in Mainz in 1495. The palace of the dukes of Acquaviva (15th century) stands on the main street. The main industries are agricultural and include wine, olive oil, grain, cattle, cheese and eggs, flour, macaroni and terra cotta.

Hatria, later Hadria, was a pre-Roman city. After becoming a Roman colony, it issued its own coins and became famous for its pottery. The family of the emperor Hadrian came from Hadria. In the middle ages it passed from the popes to the Swabians and then to the Angevins until, in 1393, it became the feudal estate of the Acquaviva family, whose descendants bear the title of dukes of Atri. In 1860 it became part of the kingdom of Italy and in World War II it was captured by the Allies in June 1944.

(TOP) ALINARI (BOTTOM) BY COURTESY OF MAU, "POMPEII, ITS LIFE AND ART" (MACMILLAN); DARTEIN "ÉTUDE SUR L'ARCHITECTURE LOMBARDE" (DUNOD)

TOP: ATRIUM OF THE "HOUSE OF THE SILVER WEDDING," POMPEII. BOTTOM. FLOOR PLANS OF ATRIA. (LEFT) HOUSE OF PANSA, POMPEII; (RIGHT) CHURCH OF SAN AMBROGIO, MILAN

ATRIUM originally may have been the central room of a Roman house in which was placed the hearth. Since this room had a hole in the roof to let out the smoke, the atrium was in essence a small court. When with the developing complexity of the Roman house the kitchen and hearth were removed to other positions the atrium remained as a court serving as a formal reception room and as the official centre of family life. By the end of the republic the addition of one or more colonnaded courts in the larger houses removed from the atrium the last vestiges of family life, and in the empire it became practically the office of the owner of the house. The atrium might be either with or without columns; it had, universally, a marble basin which was known as the impluvium. This was situated in the centre under the opening in the roof called the compluvium.

The term atrium is used in a generic sense (like the English "hall") for both consecrated and unconsecrated buildings such as the Atrium Vestae, where the vestal virgins lived, and the Atrium Libertatis, the residence of the censor, where Asinius Pollio established the first public library at Rome. The word atrium, in Rome, had a second signification, being given to any open court with porticoes around, sometimes placed in front of a temple. A similar arrangement was adopted by the early Christians with relation to the basilica, in front of which there was an open court surrounded by colonnades or arcades.

The church of San Clemente at Rome, that of San Ambrogio at Milan and the cathedral of Parenzo in Istria still retain their atria.

In medical science the term atrium is applied to the two upper chambers of the heart and also to certain other "halls" or "chambers" in the body. (T. F. H.; X.)

ATROPATENE (MEDIA ATROPATENE), anciently the district now occupied by the Azerbaijan Soviet Socialist Republic, U.S.S.R., and the Iranian provinces of East and West Azerbaijan. It formed part of the ancient Persian empire and that of Alexander, but, in the confusion after his death, secured for some time the rank of an independent state. *See* PARTHIA; PERSIAN HISTORY.

ATROPHY, in medical terminology, implies a shrinkage of

a cell, tissue or organ, either localized or spread throughout the body. Causes and effects of atrophy vary according to the structures involved and the nature of the condition. For example, muscles may atrophy because of disuse, because of paralysis or immobilization as in rheumatoid arthritis or because of degeneration of motor neurons in the spinal cord or brain as in amyotrophic lateral sclerosis (*q.v.*). Other parts of the body that may atrophy for a variety of reasons include the bones (interstitial atrophy), nerves (atrophy of the optic nerve), the tissues supporting the teeth (periodontal atrophy), either side of the face (facial hemiatrophy), the liver (acute yellow atrophy of the liver) and the skin, in certain areas of which there may be chronic localized atrophy.

ATROPINE, a poisonous, crystalline alkaloid used in medicine.

Uses.—The therapeutic uses of atropine are based for the most part on its peripheral actions. Its chief use is in ophthalmology, where it is applied locally to the eye to dilate the pupil in the examination of the retina or to break up or prevent adhesions between the lens and the iris. It was formerly used in bronchial asthma to relax the bronchial spasms, but it was largely replaced by epinephrine and other measures. It gives symptomatic relief in hay fever and head colds only by drying up the nasal and lachrymal secretions.

Since atropine relaxes intestinal spasms due to parasympathetic stimulation it is prescribed in certain types of bowel distress and is included in a number of proprietary cathartics in order to decrease griping. It is used in the treatment of childhood bedwetting and is occasionally employed to relieve ureteral and biliary spasms.

Atropine is no longer used as a respiratory stimulant, though the belladonna alkaloids, because of their central actions, have been found to give relief in certain central nervous system diseases.

The ubiquitousness of the effects of atropine is a distinct disadvantage in its clinical use, and a number of synthetic substitutes with more specific effects were introduced. Thus, homatropine has a more transient action in the eye and has little or no effect on the central nervous system, while trasentine and syntropan have the antispasmodic action of atropine without producing dilation of the pupil, dryness of the mouth or an increase in heart rate.

Pharmacology.—Atropine has a central effect, at first stimulating and later depressing the central nervous system. Its characteristic pharmacological action, however, is a depressant effect on the parasympathetic nervous system. According to the chemical theory of the transmission of nerve impulses, acetylcholine is liberated at the nerve endings of the parasympathetic fibres by impulses traveling down the nerve and in some way stimulates the effector cell.

Atropine does not interfere with the formation of acetylcholine at the nerve ending but apparently prevents it from acting on the receptor cell. Atropine also inhibits the secretory nerves of the human sweat glands, which anatomically belong to the sympathetic nervous system but which liberate acetylcholine rather than sympathin at their terminals. Acetylcholine is also liberated at the ganglionic synapses of both sympathetic and parasympathetic nerves. However atropine, except possibly in very large doses, does not interfere with the transmission of impulses at these points.

Specific effects of atropine resulting from its peripheral action include the arrest of secretion of sweat, mucus and saliva; inhibition of the vagus leading to an increased heart rate; dilation of the pupil and paralysis of accommodation; relaxation of the bronchial, intestinal and other smooth muscles. Central effects include excitement and delirium followed by depression and medullary paralysis.

Toxicology.—The symptoms of atropine poisoning have been succinctly summarized as follows: "Hot as a hare, blind as a bat, dry as a bone, red as a beet and mad as a hen." The temperature rises because of inhibition of sweating and restlessness; the pupils are widely dilated and the vision blurred; the skin is hot, dry and flushed, and a rash may appear, suggesting scarlet fever; the patient is excited and confused, hallucinations are common and the behaviour is frequently suggestive of delirium tremens. Treatment consists of gastric lavage if the poison was taken by mouth. Morphine may be given cautiously to control convulsions, while the peripheral symptoms may be treated with pilocarpine. Depression should be combated with caffeine or other stimulants. Artificial respiration may be necessary.

Chemistry.—Atropine ($CH_3.N.C_6H_{10}.CH.O.CO.CH[C_6H_5]CH_2OH$) does not occur in appreciable amounts in nature, but is derived from levohyoscyamine (*see* HYOSCYAMINE), found in various solanaceous plants (*see* SOLANACEAE), as belladonna (*Atropa*), henbane (*Hyoscyamus*), thorn apple (*Datura*) and *Scopolia*. Pure atropine crystallizes from alcohol, on addition of water, in colourless prisms, which melt at 114°–116° C. It is readily soluble in alcohol or chloroform, less so in ether, and almost insoluble in water. When atropine was first prepared in 1833 the processes in use for the extraction of alkaloids were too crude to avoid racemization of levohyoscyamine, and so the racemic isomeride, atropine, was obtained, and partially racemic mixtures were later mistaken for new alkaloids, of which "daturine," "duboisine," etc., are examples.

Atropine is made by racemization, with small quantities of alkali, of crude *l*-hyoscyamine, the best source of which is Egyptian henbane (*Hyoscyamus muticus*). The alkaloid may be extracted by the process described in the article ALKALOIDS, and is generally purified after racemization by conversion into, and recrystallization of, the neutral oxalate. Atropine forms a series of well-crystallized salts, of which the sulfate is that principally used in medicine. This salt crystallizes in long, slender, colourless needles (which break up on exposure to air to a crystalline powder) and melts at 194° C.

Both atropine and hyoscyamine have been synthesized and are known to be, respectively, the racemic and levotropic esters of tropine, and many attempts have been made to improve on them. The most successful attempt of this kind is homatropine, which is a phenylglycollic ester of tropine. *See* HYOSCYAMINE; TROPINE; *see* also Index references under "Atropine" in the Index volume.

(F. O. K.)

ATROPOS, in Greek mythology, one of the three Fates, the others being Clotho and Lachesis. Atropos' name ("unalterable" or "inflexible") indicates her function, that of rendering the decisions of her sisters irreversible or immutable. Atropos is most frequently represented with scales, a sundial or a cutting instrument, the "abhorred shears" with which she "slits the thin-spun life." *See* FATE.

ATTACHMENT, in law, a writ issuing from a court of law to seize the person or property of a defendant. In several of the older states in the U.S., attachments against property readily issue at the commencement of suits to secure any judgment which may be entered for the plaintiff. In other states, attachments before judgment issue only against the property of nonresidents or upon specific statutory grounds relating to fraud or the like. The plaintiff is commonly required to post an indemnity bond. Attachment may also issue after judgment, the term being frequently used to designate a levy upon a bank account or other intangible right of the debtor against a third party. *See* DEBTOR AND CREDITOR LAW; PRACTICE AND PROCEDURE.

(J. A. MacL.)

ATTAIGNANT, PIERRE (*c.* 1480–*c.* 1550), early Parisian music printer and publisher who was among the first to use single-impression printing. He is first mentioned in 1515. Before 1527, he took over the movable music-type of Pierre Haultin, first using it in his *Chansons nouvelles* . . . (1528). There followed an ambitious series of publications. In 1538 he was music printer and bookseller to the king. After 1549 he disappeared from public life and died before July 1553. Attaignant's prints comprise more than 30 masses, more than 300 motets, *Magnificat*, psalms and Passions; more than 2,000 *chansons*; 5 dance collections; 1[illegible] volumes for organ and 2 for lute. More than 150 composers are represented, including Josquin des Prés, Pierre de la Rue, Jean Mouton, Nicolas Gombert, Clement Janequin, Claude de Sermisy, J. Arcadelt, A. Willaert, Clément and Claude Le Jeune. His surviving publications are a mine of information for early 16th-century music.

Bibliography.—Modern reprints include *Trente et une chansons* (1529), ed. by H. Expert in *Les Maîtres musiciens de la Renaissance française* (1897); organ music, with a study, ed. by Y. Rokseth, in *Publications de la société française de musicologie*, vol. i (1925); *Treize motets et une prélude pour orgue* (1531), ed. by Y. Rokseth (1930); *Treize livres de motets* (1534–35), ed. by A. Smijers (1934–39). *See* also G. Lepreux, "Gallia typographica," supplement 1 to *Revue des bibliothèques, Série parisienne*, vol. 1, pt. i, 57–63 (1911); Y. Rihouët, "Note bibliographique sur Attaignant," in *Revue de musicologie* (May 1924); B. Guégan, "Histoire de l'impression de la musique. La typographie musicale en France," in *Arts et métiers graphiques*, 15 (Jan. 1939). (B. L. Tr.)

ATTAINDER, in English common law, refers to the extinction of civil and political rights resulting from the imposition of a sentence of death or outlawry after conviction of treason or a felony. Among the important consequences of attainder were forfeiture and corruption of blood. For treason the offender's lands were forfeited to the king. For felony they were forfeited to the king for only a year and a day and then escheated to the lord from whom the offender held his tenure, a consequence traceable to the early concept of felony as a breach of the feudal bond. The contest between king and lords for these valuable rights produced the clause of Magna Carta in which the crown renounced any claim to forfeiture on the ground of felony and contributed to the definition of high treason by statute in the reign of Edward III. Forfeiture and escheat related back to the date of the crime and ignored intermediate sales and encumbrances made by the offender. Even harsher to innocent parties was the doctrine of corruption of blood, by which the person attainted was disqualified from inheriting or transmitting property and his descendants were forever barred from any inheritance of the title which had to be traced through him. Thus if A owned land and his son, B, committed treason and was attainted, and A thereafter died, the land would escheat to A's lord even though B left a son, C, who would otherwise have inherited it. The Inheritance act of 1833 (3, 4 Wm. IV, c. 106, s. 10) abolished this doctrine. Escheat and forfeiture for felony or treason were abolished in 1870, except that forfeiture as a consequence of outlawry upon an indictment for treason was preserved (33, 34 Vic., c. 23, s. 1). The constitution of the United States provides that "Congress shall have power to declare the Punishment of Treason, but no Attainder of Treason shall work Corruption of Blood, or Forfeiture except during the Life of the Person attainted" (art. iii, sec. 3). The punishment declared by congress is death, or a minimum of five years' imprisonment and $10,000 fine plus disability from holding any office under the United States. U.S. code, title 18, sec. 2381.

A legislative act for attainting a person without a judicial trial was known as a bill of attainder (or, where punishment less than death was inflicted, as a bill of pains and penalties). The power of parliament to declare guilt and impose punishment by such measures was well established by the 15th century. During the Wars of the Roses bills of attainder were used by the rival factions to rid themselves of each other's leaders and Henry VIII induced a subservient parliament to pass such bills against ministers whom he had ceased to trust. When impeachments (*q.v.*) were revived under James I and Charles I as a method for ousting ministers unpopular with parliament, bills of attainder sometimes proved a more expeditious means to the same end, as in the famous case of the earl of Strafford who was attainted and beheaded in 1641. Unlike impeachment, a judicial proceeding in the house of lords on charges made by the house of commons, a bill of attainder was a legislative act adopted by both houses with the formal assent of the king. The offenses charged in such bills were usually characterized as treason but did not have to satisfy established legal definitions of that or any other crime. Thus bills of attainder have generally been deplored not only because they deprived the accused of a fair trial but also because of their typically ex post facto quality, making new crimes of conduct which had proved politically offensive to the dominant faction of the legislature. In England the last bill of attainder in the strict sense was that against Lord Edward Fitzgerald, who was condemned to death by act of parliament for leading the 1798 rebellion in Ireland. The last bill of pains and penalties, introduced in 1820, led to a legislative trial of Queen Caroline, George IV's wife, on charges of adultery but was not passed. Acts of attainder or of pains and penalties were passed by some of the American colonial legislatures, a notable example being the New York act of 1779 which banished and forfeited the property of 59 named Loyalists for the offense of having "voluntarily been adherent" to King George III.

The constitution of the United States forbids both congress and the states to pass any bill of attainder or, by accepted interpretation, any bill of pains and penalties (art. i, sec. 9, 10). In applying these prohibitions the supreme court has expanded the historical conception of such bills. Thus it invoked these clauses to strike down test oaths passed after the Civil War to disqualify Confederate sympathizers from practising certain professions (*Cummings* v. *Missouri*, 4 Wall. 277 [1867]; *Ex parte Garland*, 4 Wall. 33 [1867]). Similarly, it invalidated as a bill of attainder a rider to an appropriation bill forbidding the payment of salaries to named government officials who had been accused of being subversive (*U.S.* v. *Lovett*, 328 U.S. 303 [1946]). Later decisions, however, have declined to treat requirements of loyalty oaths as bills of attainder, though sometimes invalidating such requirements on other grounds. (See *Garner* v. *Board of Public Works*, 341 U.S. 716, 730 [1951] [dissenting opinions]; *Shelton* v. *Tucker*, 364 U.S. 479 [1960]).

(P. C. N.)

ATTALID DYNASTY, a line of rulers in Pergamum during the 3rd and 2nd centuries B.C. whose devotion to Hellenism made Pergamum renowned as a leading centre of Greek civilization.

The dynasty was founded by Philetaerus (*c.* 343–263 B.C.), ruler of Pergamum after 282, who was born in the Greek city of Tios, on the Black sea, of a Greek (or Macedonian) father, Attalus, and a Paphlagonian mother, Boa. He served under Antigonus I (*q.v.*) in Phrygia until 302, when he deserted to Lysimachus (*q.v.*), who shortly afterward entrusted to his keeping the fortress of Pergamum with its treasure of 9,000 talents. In 282 he transferred his allegiance to Seleucus I (*see* Seleucid Dynasty) and in return he was able to acquire a larger measure of independence than before.

The territory Philetaerus controlled was as yet quite small—no more than Pergamum and its environs—and it was largely of necessity that he curried favour with the first Seleucid kings and the Greek cities near him; his gifts to the temples at Delphi and on the island of Delos helped his family to obtain some prestige farther afield. When, after the death of Seleucus I in 280, the Seleucid grip on Asia Minor slackened, he found a chance to increase the area under his control (probably so far as to embrace the whole of Mysia); and before his death in 263 he had abandoned the Seleucids and formed a tie with Egypt.

His successors, Eumenes I, Attalus I and Eumenes II (*see* Eumenes; Attalus), carried forward the work of expansion and consolidation, although Attalus I and Eumenes II lost ground to Antiochus III (*see* Antiochus). Finally, as a result of alliance with Rome and untiring diplomatic intrigue, the ambitions of the Attalid kings were realized to the full in the treaty of Apamea (188) between Rome and Antiochus III, under the terms of which the greater part of Seleucid Asia Minor was assigned to them. The last three kings, Eumenes II, Attalus II and Attalus III, were in consequence able to play a leading part in the political life of the Hellenistic world, even though their subservience to Rome made them unpopular and circumscribed their independence.

The history of the dynasty falls into two parts: before and after the assumption of the royal title by Attalus I. It is to the second half of the latter period that most of the available evidence relates. The first two rulers had been no more than local dynasts of a type then common in Asia Minor; the kingdom, by contrast,

had a much greater political significance. In its institutions it resembled the other Hellenistic monarchies: ruler worship was practised; royal officials were graded in order of importance. One difference from the Ptolemies and Seleucids was that the Attalids lived in a more modest style and were in spirit more Greek than Macedonian; nevertheless, the power of the king was absolute throughout the kingdom. The Greek cities within the kingdom were nominally autonomous bodies, but the king was ready to intervene in their affairs. Thus, at Pergamum the usual city institutions (council, assembly, etc.) were in being, but the administration lay with a board of five generals who were not elected by the citizens but nominated by the king. The king could exercise control even more directly by royal decrees, which were observed within the city as equivalent to laws. The degree of his control over other cities varied. The ancient city-state of Aegina in the Saronic gulf was ruled by a royal governor (*epistates*) and was entirely subject to royal decrees; and after the treaty of Apamea several places paid tribute as subjects to the Attalids (they included Byzantium, Lysimachia and Sestos around the Hellespont; Phocaea, Teos, Ephesus and Sardis in western Asia Minor). But many cities, recognized as autonomous by Rome, were merely attached to the kingdom as free allies, and to these the kings behaved with a benevolence and restraint in striking contrast with their attitude to the other class of city.

The provinces of the kingdom were governed by generals (though they were not, perhaps, officially called such) after the manner of the Seleucid empire. Few new Greek foundations can be attributed to the Attalids; preferably they took over existing settlements. In this and in other respects they benefited greatly from the achievements of the Seleucids. Nevertheless, in many departments they demonstrated a remarkable flair for government, not least in their creation of a strong army and navy.

Their financial system as it concerned subject cities was peculiar in that, while they imposed heavy taxes and tribute, they also gave subsidies in money and kind that enabled the cities to meet the charges that otherwise would have been beyond their means. In general, a strict financial control was exercised in all parts of the Attalid kingdom. All the kings took a keen interest in their territory's economic life; the high degree of organization achieved and the successful exploitation of the country's natural riches are comparable to the Ptolemies' work in Egypt.

ATTALUS (PRISCUS ATTALUS) (fl. early 5th century A.D.), usurping Roman emperor, was raised to the purple in 409 by Alaric (*q.v.*), who was then besieging Rome. Hitherto a pagan, Attalus was baptized into the Arian Church by a Gothic bishop, but refused to be Alaric's puppet. After appointing Alaric to a high military office, he forbade the Goths to send forces to seize Africa. Attalus failed to depose the legitimate emperor Honorius, in whose interests the count Heraclian, who was holding Africa, stopped the transport of grain from Africa to Italy. Despite the resulting famine in Rome, Attalus again refused to allow Alaric to send an army to Africa. Alaric consequently deposed the emperor whom he had himself elevated (summer 410). Raised to the throne again in 414 by Ataulphus, Alaric's successor, who was then in Gaul, he was deserted by the Goths and fell into the hands of Honorius, who exiled him to Lipara. (E. A. T.)

ATTALUS, the name of three kings of the Attalid dynasty of Pergamum in the 3rd and 2nd centuries B.C.

ATTALUS I SOTER (269–197 B.C.), ruler of Pergamum from 241 to 197 and king from *c.* 230, succeeded his uncle Eumenes I. His mother was Antiochis, a Seleucid princess. Shortly before 230 he was attacked by the Galatians (Celts who had settled in central Asia Minor in the 3rd century B.C.), having refused to pay them the customary tribute. He completely defeated them outside the walls of Pergamum, whereupon, to mark the occasion, he took the title of king, the first of the Attalids to do so. Subsequently he defeated Antiochus Hierax (*see* ANTIOCHUS) in three battles, as a result of which he gained a brief control over all the Seleucid domains in Asia Minor apart from Cilicia (228–223). He built a fleet, bought the island of Aegina in the Saronic gulf from the Aetolians and fought alongside Rome and the Aetolians against Philip V of Macedonia (212–204). In 201 he took the side of the Rhodians in their war with Philip, and, with them, brought about by diplomatic approaches in Rome a new Roman intervention against Macedonia.

ATTALUS II PHILADELPHUS (220–138 B.C.), king of Pergamum from 160 or 159, was the second son of Attalus I and brother of Eumenes II, whom he succeeded. Before his accession he had played a prominent part in public life as the devoted aide of his brother; he commanded the Pergamene forces attached to the Romans in their campaigns in Galatia (189) and Greece (171); he visited Rome frequently as an ambassador and enjoyed great influence there. Even when Eumenes II lost the Romans' favour after 168, Attalus retained his reputation in Rome, and it was widely believed that the Romans wanted him to dispossess his brother. This he was unwilling to do.

As king Attalus maintained the former close link with Rome. with the connivance of the Romans he aided the pretender Alexander Balas (*q.v.*) against the Seleucid king Demetrius I; and with their help he held his own against Prusias II, the aggressive king of Bithynia.

ATTALUS III PHILOMETOR EUERGETES (d. 133 B.C.), king of Pergamum from 138 to 133 B.C., a son of Eumenes II and nephew of Attalus II. Little is known of his reign. He is said to have behaved tyrannically at first but later to have lived a quiet and studious life. When he died it was found that his will bequeathed the kingdom to Rome (*see* ASIA, ROMAN PROVINCE OF). His motives in making this bequest are obscure. *See* ATTALID DYNASTY. (R. H. SI.)

ATTAR: *see* FARID UD-DIN 'ATTAR.

ATTAR OF ROSES, otherwise known as "otto of rose," is an essential oil distilled mainly from the pink damask rose *Rosa damascena*. By far the major source is Bulgaria, where the growing of roses in the humid valleys and the subsequent distillation have become an important, highly modernized state enterprise. Some attar is also produced commercially in Turkish Anatolia. It takes about 250 lb. of roses to produce a single ounce of the expensive, richly perfumed attar. In the south of France and in Morocco, other types of rose oil are obtained, partly by distilling but principally by the solvent extraction of centifolia roses (*R. centifolia*). Rose water is a by-product of distillation. Rose oils are invaluable ingredients of fine perfumes and liqueurs. (F. V. Ws.)

ATTAWAPISKAT, a river of northern Ontario, Can., issuing from Attawapiskat lake (elevation 815 ft.) midway between Lake Superior and Hudson bay and flows in an easterly direction to James bay, having its mouth west of Akimiski Island. For most of its 465 mi. (including headwaters) the river is sluggish, alternating with short, swift and rapid stretches which do not make portages necessary. The lower 135 mi. is full of islands and leads through almost level, swampy country. Timber decreases down river. Lansdowne House on Attawapiskat lake and Attawapiskat at its mouth are trading posts. (AN. KR.

ATTENTION, as typically used in spoken or written communication, means the selective process by which certain events in the environment come to be consciously perceived. That of which a person is clearly aware at a given instant is said to be attended to. For example, while conversing with a friend, I pay attention to the words he is speaking and ignore the voices of others around me. I attend to the picture on the television screen and fail to notice persons that enter or leave the room. I listen attentively to the melody played by the violin and have only a vague awareness of the background provided by other instruments of the orchestra. The scientist interested in discovering systematic relationships between environmental events and sensory experience has found that he also has to take into account this selective process which is called attention.

In the early days of experimental psychology, investigators attempted to break down conscious experience into its elements. The method used was that of introspection under carefully controlled conditions. A number of attributes or discriminable di-

mensions of sensory experience were agreed upon by most investigators; these included intensity, quality, duration and spatiality. But it became evident that sensory experiences could not be completely described in terms of these characteristics; a fifth attribute, clearness or attensity, had to be added. A visual object, for example, not only could vary in such characteristics as its brightness, its colour, the length of time it was present and its size, but it also could occupy the centre of consciousness to a greater or lesser extent—it could be clearly perceived or be in the periphery of awareness. The process which had to do with controlling this aspect of sensory experience was called attention.

As the science of experimental psychology developed, psychologists ceased to be concerned with the introspective analysis of sensory experience. Instead, experiments dealing with sensation and perception usually fell into one of three classes: (1) psychophysical experiments in which a physical stimulus was systematically varied and the responses (verbal or nonverbal) of a living organism (man or lower animal) were observed and measured; (2) physiological experiments in which again a physical stimulus was varied but a physiological event such as discharge of nerve impulses or change in blood pressure was measured; or (3) a psychophysiological experiment in which physiological events were manipulated (*e.g.*, by administration of drugs or by damage to the central nervous system) and behaviour of the organism measured.

Psychophysical Studies.—Numerous psychophysical experiments (*see* PSYCHOPHYSICAL METHODS) have been done in which factors which influence or control attention have been examined. It has been shown, for example, that the direction of attention is determined by such characteristics of a stimulus object as its size, intensity, duration, novelty and relation to other stimulus objects in the environment. That object which is attended to is also determined by subjective factors; *i.e.*, characteristics of the person who is attending. His sensory capacities, interests, needs, past experiences and level of alertness or wakefulness are all factors which may be important in determining the direction of attention at any given time.

In other experiments, attempts have been made to answer such questions as: How long can attention be maintained on one particular stimulus object? What conditions influence fluctuation or shifting of attention? Can two or more objects be attended to at one time? Simple answers cannot be given to these questions because there are numerous conditions which affect the experimental results obtained. In several experiments, however, it has been found that attention to one object can be maintained for about five to ten seconds. Tests have been made with objects seen, heard and felt. Fluctuations of attention may be due to adaptation of the sense organs, to slight movements of the sense organs (particularly in the case of vision) or to slight changes in the stimulus conditions. Most experimental evidence indicates that two objects cannot be attended to at one time. Rapid shifting of attention makes it possible for a person to carry on two tasks simultaneously; *e.g.*, adding a column of numbers and listening to a story which later must be recalled.

Physiological Studies.—From studies of electroencephalograms, which record the electrical activity of the brain by means of electrodes placed on the skull or directly on the brain, it is known that a change in the pattern of recorded activity occurs if a light or sound is presented to a resting, relaxed subject. The brain wave pattern changes from one of slow waves of high amplitude to one of fast waves of relatively low amplitude. This change is referred to as activation of the EEG, or arousal response. It seems to be related closely to the degree of general alertness or attentiveness of the subject whose electroencephalogram is being recorded.

Experiments done on animals have shown that a similar arousal response or activation of the EEG may be produced by electrical stimulation of the brain stem reticular formation. This consists of a complex of nuclei extending along the core of the brain stem from the level of the medulla to the thalamus. Boundaries and subdivisions of individual nuclei within the total complex are not well known. Whereas stimulation of the brain stem reticular formation produces the EEG activation response, surgical removal of the anterior portion in an experimental animal produces somnolence or, if the damage is extensive, a comatose state. These and other kinds of evidence suggest that the brain stem reticular formation plays an important role in the maintenance and control of attention, alertness and consciousness.

Closely related functionally to the brain stem reticular formation is a group of thalamic nuclei referred to as the unspecific thalamocortical projection nuclei. While the anatomical connections between these thalamic nerve centres and the reticular formation are not known clearly, evidence from electrophysiological studies indicates that the unspecific thalamic nuclei as well as the brain stem reticular formation project diffusely to the cerebral cortex. Also, like the reticular formation, the unspecific projection nuclei of the thalamus appear to play an important role in the control of attention. Experimental evidence suggests that the reticular formation is important in the control of the general state of alertness or wakefulness and that the unspecific thalamic nuclei may be concerned in such processes as directing and shifting of attention.

While recognizing that the brain stem reticular formation and unspecific thalamocortical projection system play highly critical roles in the control of consciousness and of attention, the fundamental importance of the main pathways from sense organs such as the eye and ear to the cerebral cortex should not be overlooked. It is in the pathways and centres of the primary sensory systems that the information coming from the sense organs is processed for use in guiding or controlling behaviour. For an understanding of the neurophysiological processes underlying attention, knowledge of the patterns of interaction between the reticular formation and unspecific thalamocortical projection system on the one hand and the primary sensory systems on the other is essential. Furthermore, it is necessary to clarify the neuroanatomical and neurophysiological relationships of these systems with those parts of the brain which have to do especially with the processes of emotion and motivation.

Psychophysiological Studies.—In laboratory experiments, the behaviour of animals is often tested before and after removal of parts of the brain or transection of neural pathways. In the clinic, operations are made on human patients after damage to the central nervous system, the damage being done by accident, disease or neurosurgical procedures designed to alleviate conditions produced by accident or disease.

As noted above, damage to the brain stem reticular formation of an experimental animal can produce a somnolent or comatose state depending on the locus and extent of the damage. In some cases, the animal may sleep except when aroused by strong sensory stimulation and will quickly return to sleep when stimulation ceases. With more severe damage, arousal becomes impossible.

In both experimental studies of animals and clinical studies of man, cases have been described in which deficiencies in ability to attend have resulted from damage to the cerebral cortex. It has been shown, for example, that after surgical removal of the auditory projection areas of the cerebral cortex an experimental animal can still respond to very weak sounds and can discriminate small differences in the frequency or intensity of sounds; in discriminations which require that activity for a short period of time be guided by a sound cue or that a series of cues be utilized, however, the animal may behave in such fashion as to suggest that it is deficient in ability to maintain attention. Similarly a patient with damage to the cortical area which has to do with the sensation of touch in the left hand may be able to respond to light touch of that hand, but he may fail to recognize or even be aware of an object placed in the left hand if at the same time a second object is placed in the right hand, the latter being unaffected by the cortical damage. If, however, the object in the right hand is removed, that in the left hand may then be felt and recognized. This and similar phenomena which have been noted in the clinic may be described as deficits in ability to attend. *See* also PERCEPTION; PSYCHOLOGY, EXPERIMENTAL.

ATTERBOM, PER DANIEL AMADEUS (1790–1855), the first in the line of Sweden's great romantic writers. The son of a clergyman in Östergötland, he was born on Jan. 19, 1790, at Åsbo. At 15 he went to Uppsala and there, with some friends, founded in 1807 the society Musis Amici, rechristened the following year Auroraförbundet. Its publication, *Phosphoros* (1810–13), together with the organ of the Stockholm romantics, *Polyfem* (1809–12), initiated the literary revolution in Sweden. Atterbom contributed to both, in the former as the leading poet and essayist of "the new school," in the latter as an acid polemical writer in the battle against the "old" pseudoclassical school. A distinctive feature of *Phosphoros*, as of Atterbom himself, is an adhesion to Schelling's nature philosophy and aesthetics. This led to the Uppsala romantics' early rejection of extreme German romanticism in favour of the classicism of Goethe and Schiller. Atterbom also contributed industriously to *Poetisk kalender* (1812–22), which was modeled on the German poetic calendars, and to *Svensk literaturtidning* (1823–24), which became a leading Swedish periodical of literary criticism.

Atterbom is famed as the poet of *Blommorna* ("The Flowers"; 1812–37). In his first poems about flowers he shows how nature's cycle, from budding vernal life to autumnal decay and death, teaches that the changes in human life and in civilization also point to an eternal existence beyond death and annihilation. In the unfinished fairy play *Fågel blå* ("The Blue Bird") similar thoughts are to be found. The writer's greatest poetic work, the fairy play *Lycksalighetens ö* ("The Isle of Bliss"; 1824–27), treats the story of King Astolf, who leaves his northern kingdom for the temptations of sensual beauty beyond duty and calling—a symbolical representation of the beguiling power of imagination in the history of poetry.

At his death Atterbom was working on his great *Svenska siare och skalder* ("Swedish Prophets and Poets"), in seven volumes, where he does justice to the writings which, with the recklessness of youth, he had earlier attacked. The style and erudition of this work give him the rank of Sweden's first great literary historian. He died at Stockholm on July 21, 1855.

Atterbom's complete works were published in 13 vol. (1854–70). A selection was published in 6 vol., *Valda Skrifter* (1927–29).

See C. Santesson, *Mot Lycksalighetens ö. Atterbomstudier* (1956); H. Frykenstedt, *Atterboms livs och värlolsåskådning* (1951). (H. E. U. F.)

ATTERBURY, FRANCIS (1663–1732), English bishop, was a zealous participant in many of the literary, political and ecclesiastical controversies of his time. He was born at Milton, Buckinghamshire, where his father was rector, on March 6, 1663, and was educated at Westminster school and at Christ Church, Oxford. He became a tutor of his college and a close associate of the dean, Henry Aldrich, a leader of Oxford Toryism after 1688. Through this connection Atterbury became involved in Charles Boyle's unmannerly attack upon Richard Bentley, himself writing (1698) much of Boyle's defense of the authenticity of the *Epistles of Phalaris*.

Atterbury took holy orders in 1687. After his appointment as lecturer at St. Bride's Fleet street in 1691, and as preacher at Bridewell hospital in 1693, an increasing number of engagements, including sermons at court, caused him to spend much of his time in London. A fanatical supporter of the high church party, he led the agitation for the revival of convocation, which had not assembled since 1664. As a result of his campaign, sessions were renewed in 1701, and the bishop of Exeter appointed Atterbury archdeacon of Totnes, thus enabling him to be a member. He was made dean of Carlisle in 1704. His primary object achieved, he now employed his taste for controversy in vindicating the constitutional powers of the lower house of convocation and in provoking many clashes with the Erastian bishops. When Henry Sacheverell's sermons castigating the Whig ministry for their neglect of the church led to his impeachment in 1710, Atterbury helped to frame his defense. Atterbury became prolocutor of the lower house of convocation in the same year. He had gained Queen Anne's favour and in 1711 she appointed him to succeed Aldrich as dean of Christ Church. But he did not prove a good college administrator and after being consecrated bishop of Rochester in 1713, he left Oxford.

Events now diverted Atterbury's energy to politics. He was among those who had hoped to set aside the Act of Settlement and establish James (the Old Pretender) as Queen Anne's successor. However, he took the oath of allegiance to George I in 1714, but his attempts to ingratiate himself with the new court were ill-received and he drifted steadily into the Jacobite camp. On the occasion of the 1715 rebellion he refused to sign an address of loyalty; and by 1717 he was in correspondence with James. He was arrested in Aug. 1722, charged with complicity in a Jacobite plot; after nearly ten months in the Tower of London he was sentenced to deprivation and exile. He went first to Brussels and thence to Paris, where by 1725 he had become James's principal agent; but quarrels and jealousies led to his resignation two years later. He lived in retirement at Montpelier from 1728 to 1730 but then returned to Paris where he was again in James's service until his death on March 4, 1732.

Atterbury was a member of the Scriblerus club (formed *c.* 1713), and Swift, Pope and Matthew Prior were among his friends. He wrote a little verse and made some translations from classical poets; but his contribution lay in his topical polemic writings and in his role as pacemaker for his more brilliant associates.

See F. Williams, *Memoirs and Correspondence of Francis Atterbury* (1869); H. C. Beeching, *Francis Atterbury* (1909).

ATTESTATION, the execution of certain solemn documents, such as deeds and wills, in the presence of statutorily required witnesses who themselves sign the document and who must, if available, be called to identify the document in subsequent proceedings involving it or questioning its validity. *See* OATH AND AFFIDAVIT. (R. E. DE.)

ATTHIS (an adjective meaning "Attic"), the name given to a monograph or special treatise on the religious and political history, antiquities and topography of Attica and Athens. The first of the atthidographers was Hellanicus of Lesbos, who committed to writing part of the tradition about early Athens which even in his time (late 5th century B.C.) was still mainly oral. About two generations later began a succession of Athenian writers on these topics (the approximate dates of whose writings are given in parentheses): Clidemus, called Clitodemus by Pausanias (*c.* 350 B.C.); Androtion (*c.* 340 B.C.); Phanodemus (*c.* 340–330 B.C.); Melanthius (date uncertain); Demon (*c.* 300 B.C.); and Philochorus (who lived *c.* 340–262 B.C.). The work of Ister "the Callimachaean" (*i.e.*, pupil of the poet and critic Callimachus) was not a true *Atthis*. Although no written records existed in Athens from earlier than 682 B.C., and very few for about two centuries thereafter, these writers were not deterred from beginning at the beginning, and did not draw the line at mythology. Indeed they turned mythology into history, sometimes with a wealth of corroborative detail, as in the story (preserved in Plutarch's *Life of Theseus*) of a great victory on Athenian soil over the Amazons.

Not one of the *Atthides* has survived even in part, but from references and short quotations in surviving literature it seems that they differed from each other in material probably very little but quite significantly sometimes in their interpretation. Of these writers only Androtion was a professional politician, but it is no accident that Athenians wrote histories of Athens only in the age when there had developed the threat (sometimes the reality) of foreign domination. They were a kind of reply to those (*e.g.*, Isocrates) who advocated collaboration. The past of Athens, in all its variety and its moments of glory, was told and retold by writers who saw it whether as radical democrats (Clidemus) or as conservatives like Androtion and Philochorus. The works of Clidemus, Androtion and Phanodemus, their views of the past all coloured by their own political complexions of the present, were available to Aristotle (or his pupil) in writing his *Constitution of the Athenians*, in which the occasional lapses from unity may arise partly from the diversity of these sources.

BIBLIOGRAPHY.—F. Jacoby (ed.), *Die Fragmente der griechischen*

Historiker, IIIB., no. 323a–328 (1950–54), *Atthis* (1949); L. Pearson, *The Local Historians of Attica* (1942). (G. T. Gr.)

ATTIC, in architecture, any portion of wall raised above the main cornice, utilized by the Romans principally for decorative purposes, inscriptions, etc., as in triumphal arches. It was developed in the Renaissance as an important part of a façade, frequently enclosing an additional story, the windows of which were treated as part of the decoration. In modern usage the word is also employed to designate a story immediately under the roof, especially when the roof is of steep pitch.

ATTICA (Gr. ATTIKE; modern ATTIKI) a district of 1,000 sq.mi. in ancient Greece comprising part of the modern department (*nomos*) of the same name (1,470 sq.mi.). With its administrative centre at Athens (*q.v.*), the modern department extends farther westward than ancient Attica to include Megara on the Isthmus of Corinth. The ancient district was bounded by Boeotia in the north (the frontier extending from Mt. Cithaeron to Mt. Parnes), by the Euboean channel in the east, by the Aegean sea in the southeast, by the Saronic gulf in the south and by Megarian territory in the west. The name was probably derived from the peninsular (*Aktike*) character of the district, which terminates in the headland of Sunium. The southern coast has the most sheltered waters and contains the sandy beach of Phalerum, where small craft can be drawn on shore, and the deep-water inlets of the Piraeus on the west and Zea on the east of the promontory of Munychia. Thus Attica is well qualified to attract the maritime trade that enters the Saronic gulf en route for the west via the Corinthian canal or that in antiquity was conveyed by land across the neck of the Isthmus of Corinth.

The climate of Attica is particularly fine. The cold of winter and the heat of summer are both tempered by the influence of the sea. The long summer and much sunshine favour the growth of the olive, vine and fig, and the annual rainfall of 16 in. is adequate for cereals. The air is exceptionally dry and clear. The light on a summer day is brilliant, and the colours of sea, sky and land are strong and pure.

The frontier between Boeotia and Attica is formed by the eastern outliers of Mt. Cithaeron (4,623 ft.) and the range of Mt. Parnes (4,636 ft.), and the main road from Thebes to Athens crosses the limestone watershed at a height of about 2,000 ft. above Kriekouki (near the ancient Erythrae). This strategic area was contested between Boeotia and Attica in ancient times, and it is picketed by the ruined fortresses of Eleutherae and Panactum. The pass that was called Dryoscephalae or Treis Cephalae (modern Drios Kefalae) had great importance in the campaign of Plataea in 479 B.C. (*see* GRECO-PERSIAN WARS). A more direct path from Thebes to Athens crosses the western flank of Mt. Parnes by the ruined fortress of Phyle (modern Kastro). Between the eastern spurs of Mt. Parnes and the sea there is easy, low-lying country by Aphidna and Decelea (the railway enters Attica there); the territory of Oropus on the north of the gap was annexed to Attica in the 5th century, lost in 412 to Boeotia and changed hands repeatedly. The frontier between Megaris (part of the Isthmus of Corinth) and Attica was formed by the limestone masses of Mt. Pateras (3,714 ft.) and Mt. Keratos (1,542 ft.). It is crossed at the northern end by an easy pass west of Villia (probably the ancient Oenoe), and at the southern end the main road and railway from Megara to Athens follow the gap between Mt. Keratos and the sea. Thus the land frontiers were relatively easy to defend. Moreover, Attica lay just off the main route in antiquity between central Greece and the Peloponnese, which ran through Megaris by way of Ayios Vasilios and Tripodiscus (7 mi. N.W. of Megara).

Within the frontiers the chief feature is the central plain, bounded on the east by Mt. Hymettus (3,366 ft.) and Mt. Pentelikon (3,638 ft.), on the north by Mt. Parnes and on the west by Mt. Aegaleos (1,535 ft.). The plain of light fertile soil, watered by the Cephissus river, was farmed in antiquity by Athenian families that claimed to be autochthonous. The dominant feature of the plain is the city of Athens, built on the slopes of the acropolis hill and crowned by the Parthenon, the temple of the virgin goddess Athena. The city has the further advantage of proximity to the beach of Phalerum and the ports of Piraeus and Zea, which were included in its walled defenses during the 5th century B.C. West of the central plain a pass between Mt. Aegaleos and Mt. Parnes was defended in the 4th century B.C. by a wall, known as the Dema, but the direct route to the fertile Thriasian plain passed over Mt. Aegaleos along the Sacred Way to Eleusis, where Demeter was worshiped as goddess of the earth. Another Cephissus waters the Thriasian plain; it rises in Mt. Cithaeron above Villia. Passage from the central plain to the northeastern hill country is easy, and the main road runs from Decelea to Oropus on the coast. The wide gap between Mt. Pentelikon and Mt. Hymettus, where the tyrant Pisistratus defeated the Athenians in 546 B.C., contains the roads that lead northeastward to Marathon and Rhamnus and southeastward to Porto Raphti (the ancient Prasiae), Thoricus and Sunium. The Persians landed in this remote part in 490 B.C. and were defeated at Marathon.

The natural resources of Attica are varied. Mt. Parnes affords summer pasture and carries some forests of fir; the western hills especially are thickly wooded with evergreen scrub and the dwarf oak from which charcoal is made; some of the coastal hills are clad with woods of Mediterranean pine and with maquis scrub. The rolling lowlands, especially on the western side of the central plain and in eastern Attica, are rich in olive groves and vineyards. The plains yield cereals—wheat round Eleusis and barley elsewhere—and a variety of vegetables and pulse. In Neolithic times, when Attica was sparsely settled, the country was heavily wooded and wild animals included the brown bear. The poems and coins of Solon (archon 594/593 B.C.) refer to the wolf and fox and to hunting; to pasturing of sheep, mules and horses, and to the making of butter, presumably from sheep's milk; to harvesting of wheat, grapes and olives; and to fishing and seafaring. Thereafter as Attica became deforested and eroded, the population exploited the mineral resources of Laurium in southeastern Attica—silver, zinc, lead and iron—the marbles of Mt. Pentelikon and Mt. Hymettus and the fine clays from which Attic pottery was made.

Athenian tradition and archaeological discovery show that there were a number of independent settlements in Attica in early times, with centres of organization at Eleusis, Athens and Marathon. The country was unified by Theseus, who established a central government at Athens. (His lifetime fell in the 13th century B.C. if the genealogical setting provided by Homer and Thucydides is accepted.) The unification was celebrated for centuries at the *Synoikia* ("festival of union") in honour of the goddess Athena. Thereafter the history of Attica became the history of Athens.

(N. G. L. H.)

ATTICUS, TITUS POMPONIUS (109–32 B.C.), Roman *eques* ("knight"), Epicurean and patron of letters, best remembered for his connection with Cicero, with whom he was educated, was born in Rome three years earlier than his friend. His name was Titus Pomponius, that of Atticus being given him later from his long residence in Athens (88–65 B.C.) and his intimate acquaintance with Greek literature and language; he assumed the name of Quintus Caecilius Pomponianus when his rich uncle, Q. Caecilius, died in 58.

When Pomponius was still a young man his father died, and he prudently transferred himself and his fortune to Athens in order to escape the civil war, in which he might have been involved through his connection with the murdered tribune, Sulpicius Rufus. He lived quietly, devoting himself to study and business interests, especially banking and moneylending; in 68 he bought an estate in Epirus.

On his return to Rome he kept aloof from political life, attaching himself to no particular group and continuing on intimate terms with men so opposed as Caesar and Pompey, Antony and Octavian. His most intimate friend, however, was Cicero, whose correspondence with him extended over many years.

Atticus' private life was happy. He did not marry until 56 B.C.,

and his only child became the wife of Agrippa, the minister of Augustus. In 32, being incurably ill, he starved himself to death.

Of his writings none is extant, although he wrote a history, in Greek, of Cicero's consulship, a Roman history down to 54 B.C. and genealogical works. His most important work was the edition of the letters addressed to him by Cicero. He formed a large library at Athens, and engaged a staff of slaves to make copies of valuable works.

Winstedt, Loeb Classical Library (1912–18). (H. H. So.)

ATTILA (d. 453), king of the Huns from 434 to 453, one of the greatest of the barbarian rulers who assailed the Roman empire, known in western Europe as the "Scourge of God," at first ruled jointly with his elder brother Bleda. The empire which they inherited from their uncle Rua seems to have stretched from the Alps and the Baltic in the west to somewhere near the Caspian sea in the east (*see* HUNS). Their first known action on becoming joint rulers was the negotiation of a peace treaty with the East Romans at the city of Margus (Pozarevac), by which the Romans undertook to double the subsidies which they had been paying to the Huns and in future to pay 700 lb. of gold each year.

From 435 to 439 the activities of Attila are unknown, but he seems to have been engaged in subduing barbarian peoples to the north or east of his dominions. The East Romans do not appear to have paid the sums stipulated in the treaty of Margus, and so in 441, when their forces were occupied in the west and on the eastern frontier, Attila launched a heavy assault on the Danubian frontier of the Roman empire. He captured and razed the important cities of Viminacium (Kostolac), Margus, Singidunum (Belgrade), Sirmium (Mitrovica) and other places. The Romans managed to arrange a truce for the year 442 and recalled their forces from the west. But in 443 Attila resumed his attack. He began by taking and destroying Ratiaria (Archar) on the Danube and then drove into the interior of the empire toward Naissus (Nish) and Serdica (Sofia), both of which he also destroyed. He next turned toward Constantinople, took Philippopolis, defeated the main Roman forces under Aspar (*q.v.*) in a succession of battles and so reached the sea both north and south of Constantinople. It was hopeless for the Hun archers to attack the great walls of the capital, so Attila turned on the remnants of the Roman forces, which had withdrawn into the peninsula of Gallipoli, and destroyed them. In the peace treaty which followed he obliged the Romans to pay the arrears of tribute, which he calculated at 6,000 lb. of gold, and he trebled the annual tribute, henceforth extorting 2,100 lb. of gold from the Romans each year.

Attila's movements after the conclusion of peace in the autumn of 443 are unknown. He murdered his brother Bleda *c.* 445 and thenceforth ruled the Huns as an autocrat. In 447, for reasons which have not been recorded, he made his second great attack on the Eastern Roman empire, but little is known of the details of the campaign. It was planned on an even bigger scale than that of 441–443, and its main weight was directed toward the provinces of Lower Scythia and Moesia; *i.e.*, farther to the east than the earlier assault. He engaged the Roman forces on the Utus (Vid) river and defeated them, killing their commander Arnegisclus, but he himself suffered serious losses. He then captured Marcianopolis, devastated the Balkan provinces and drove southward into Greece, where he was only stopped at Thermopylae. Nothing is known of the further course of this invasion. The three years following it were filled with complicated negotiations between Attila and the diplomats of Theodosius II. Much information about these diplomatic encounters has been preserved in the fragments of the *History* of Priscus of Panium, who himself visited Attila's headquarters in Walachia in company with a Roman embassy in 449. The treaty by which the war was terminated was harsher than that of 443; the Romans had to evacuate a wide belt of territory south of the Danube, and the tribute payable by them was continued though the rate is not known.

Attila's next great campaign was the invasion of Gaul in 451. Hitherto, he appears to have been on friendly terms with the Roman general Aetius (*q.v.*), the real ruler of the west at this time; and his motives for marching into Gaul have not been recorded. He announced that his objective in the west was the Visigothic kingdom centred on Tolosa (Toulouse) and that he had no quarrel with the western emperor, Valentinian III. But in the spring of 450 Honoria, the emperor's sister, sent her ring to Attila asking him to rescue her from a marriage which had been arranged for her. Attila thereupon claimed Honoria as his wife and demanded half the western empire as her dowry. He also became involved in a dispute with Aetius about the succession to the chieftainship of the Ripuarian Franks. When Attila had already entered Gaul, Aetius reached an agreement with the Visigothic king, Theodoric I, to combine their forces in resisting the Huns. Many legends surround the campaign which followed. It is certain, however, that Attila almost succeeded in occupying Aurelianum (Orléans) before the allies arrived. Indeed, the Huns had already gained a footing inside the city when Aetius and Theodoric forced them to withdraw. The decisive engagement was the battle of the Catalaunian plains (*q.v.*), or, according to some authorities, of Maurica (both places are unidentified). After fierce fighting, in which the Visigothic king was killed, Attila withdrew and shortly afterward retired from Gaul. This was his first and only defeat.

In 452 the Huns invaded Italy and sacked several cities, including Aquileia, Patavium (Padua), Verona, Brixia (Brescia), Bergamum (Bergamo) and Mediolanum (Milan); Aetius could do nothing to halt them. But the famine and pestilence which were raging in Italy in that year compelled them to leave without crossing the Apennines.

In 453 Attila was intending to attack the eastern empire, where the new emperor Marcian had refused to pay the subsidies agreed upon by his predecessor Theodosius II. But during the night following his marriage to a girl named Ildico he died in his sleep. Those who buried him and his treasures were subsequently put to death by the Huns so that his grave might never be discovered. He was succeeded by his numerous sons, who divided his empire between them.

Priscus, who saw Attila when he visited his camp in 449, described him as a short, squat man with a large head, deep-set eyes, flat nose and a thin beard. He was of an irritable, blustering, truculent character and a very persistent negotiator, but by no means pitiless. When Priscus attended a banquet given by him, he noticed that Attila was served off wooden plates and ate only meat, whereas his chief lieutenants dined off silver platters loaded with dainties. No detailed description has survived of any of his battles, so that his qualities as a general cannot be precisely estimated; but his successes before the invasion of Gaul are very impressive.

ATTIS (ATYS), a deity worshiped in Phrygia, Asia Minor, and later throughout the Roman empire, in conjunction with the Great Mother of the Gods. Their worship included the celebration of mysteries annually on the return of the spring season. Attis was confused with Pan, Sabazius (*q.v.*), Men and Adonis, and there were resemblances between the orgiastic features of his worship and that of Dionysus. His resemblance to Adonis led to the theory that the names of the two are identical and that Attis is only the Semitic companion of Syrian Aphrodite grafted onto the Phrygian Great Mother worship. It is likely, however, that Attis, like the Great Mother, was indigenous to Asia Minor adopted by the invading Phrygians and blended by them with a deity of their own.

According to Pausanias, Attis was a beautiful youth born of the daughter of the river Sangarius; he was descended from the hermaphroditic Agdistis, a monster sprung from the earth by the seed of Zeus. Having become enamoured of Attis, Agdistis struck him with frenzy as he was about to be married with the result that Attis castrated himself and died. Agdistis in repentance pre-

vailed upon Zeus to grant that the body of the youth should never decay or waste.

According to Arnobius, Attis emasculates himself under a pine tree, at the foot of which violets sprang from his blood. The Great Mother and Agdistis carry the pine tree to her cave, where they wildly lament the death of the youth. Zeus grants the petition as in the version of Pausanias, but permits the hair of Attis to grow and his little finger (which has been interpreted as the phallus) to move. In the version of Diodorus, the Mother is the carnal lover of Attis (her son), and, when her father discovers her fault and kills her lover, roams the earth in wild grief.

In Ovid's *Fasti* she is inspired with chaste love for Attis, which he pledges himself to reciprocate. On his proving unfaithful, the Great Mother slays the nymph with whom he has sinned, whereupon in madness he mutilates himself as a penalty.

Another form of the legend (Pausanias), showing the influence of the Aphrodite-Adonis myth, relates that Attis, the impotent son of the Phrygian Calaus, went into Lydia to institute the worship of the Great Mother, and was there slain by a boar sent by Zeus. Attis was originally a god of vegetation, or tree spirit, as is indicated by his association with the pine tree, into which he was said to have been afterward changed. In his self-mutilation, death and resurrection he represents the fruits of the earth, which die in winter only to rise again in spring. *See* also GREAT MOTHER OF THE GODS.

See J. G. Frazer, *The Golden Bough: Adonis, Attis, Osiris*, 2 vol. (1955). (G. S.)

ATTITUDE is a word having no precise technical meaning when used to describe human beings psychologically. It refers, in a general way, to inclinations, presumed to be enduring, to react in a certain way in response to certain kinds of situations, to see and interpret events according to some predisposition and to organize opinions into coherent interrelated clusters. Thus, for example, if a person is presumed to have a "hostile attitude" toward some organization, this person is expected to show evidence of hostility in his overt behaviour in connection with this organization, to interpret facts about the organization's structure and activities in a negative manner and to hold a variety of opinions about issues and events which are consistent with his hostile attitude. There are no very clear distinctions between "attitudes" and phrases like "opinion clusters," "belief systems" and "value systems."

Since an attitude is thought to be something inside the person which possesses the characteristics of an inclination or a predisposition, the question of how an attitude may be measured or identified becomes important. In principle, such measurement can be made only through observation of what the person says or does. What a person says, however, is not always in accordance with what he does. For example, during an interview a person might express opinions, ideas and values from which it would be concluded that his political attitudes are very conservative. It might be found also, however, that he actually belonged to a political party which mostly espoused liberal views. Which of these, then, reflects the person's attitude? In general, behaviour is affected by many things, relevant attitudes being only one part of the totality of important factors. In the above hypothetical example, the person may belong to the liberal political organization mainly for business reasons. Thus, generally, behaviour would be expected to be influenced by attitude but would not be a good direct measure of attitude.

What a person says in answer to questions is a more direct measure of attitudes in the sense that what he says will be affected mainly by his attitudes, provided the interview is conducted properly. If the interview is not conducted properly, what the person says may be completely invalid as a measure of his attitude. Thus, the manner and appearance of the person doing the interviewing, the way the question is asked and what the respondent feels is the correct or socially acceptable answer may all serve to distort the obtained measure of the respondent's attitude. Nevertheless, it is possible to obtain valid measures of specific attitudes by asking questions. Typically, questionnaires designed to measure attitudes ask for expressions of opinions on specific matters related to the general attitude being measured, ask for expressions of preference among various alternatives or ask the respondent to state what he would do in a number of specified situations. Such attitude scales are pretested to ensure that the numerical score derived is a reliable and valid indicator of the attitude.

These problems of measurement have received considerable attention. One requirement of any series of questions designed to measure a specific attitude is that it be homogeneous or unidimensional. This means, specifically, that all the questions should reflect the same attitude. If the answers to some questions reflect more than one attitude, or if some questions reflect one attitude while other questions on the same scale reflect a wholly different attitude, then the score derived from the series of questions may be ambiguous and difficult to interpret. Thus, to put it simply, in a series of questions intended to measure attitudes toward labour unions, for example, it would be best if every question produced an answer affected solely by the respondent's attitude toward labour unions and by nothing else. This is not always possible to ensure. Frequently, questions which seem to be directed at one thing turn out to be affected by others.

Attitude questionnaires are evaluated for degree of homogeneity or unidimensionality by analyzing the internal consistency of the responses made to the questions. The exact nature of the internal consistency required of answers depends upon the nature of the questions. The simplest case is that in which each question reflects a cumulatively greater degree of the attitude in question. Under these circumstances, unidimensionality is reflected in the following way: if a person has answered "yes" to the question requiring the greatest degree of the attitude, he presumably also answers "yes" to every other question; if a person has answered "no" to the one reflecting the greatest degree but has answered "yes" to the question reflecting the next greatest degree of the attitude, he would presumably answer "yes" to all the remaining questions, and so on. An analogue here would be a test of some ability. If a person has passed a very difficult item on a test, and if all the items on the test measure the same ability, the person would be expected also to pass all the easier items.

Apart from the problems of attitude measurement, research has been concentrated on questions such as: How do attitudes develop and how do they change? What relationships exist between attitudes and behaviour? What relations are there between attitudes and personality characteristics?

Social factors are probably the major determinants of the content of attitudes (*see* PSYCHOLOGY, SOCIAL). What other people say and do, how they feel, what they value, their inclinations and preferences tend to become accepted as the correct and proper way to act and feel. On issues where there is near uniformity, attitudes will develop easily and strongly. What exists uniformly will generally be accepted as the way things are and the way they must be. Very few people will question generally accepted attitudes to the effect that, for example, home, mother, family are good and highly valued things while laziness, lack of ambition and sin are bad things. Such nearly uniform attitudes may be said to be part of the culture. They develop readily in children, become highly stable and are rarely challenged. Many of these widespread attitudes are taken so much for granted that people are hardly aware that they are attitudes and values rather than "human nature."

Many attitudes, of course, are not uniform in the culture; development of these depends more on the local social situation. Thus, a child who grows up in an atheistic family will develop attitudes toward religion different from those of a child who grows up in a very religious family; a child who grows up in the state of Georgia will most likely have attitudes toward Negroes different from those of one who grows up in Minnesota. Such attitudes are more likely to be challenged and subjected to influence and, consequently, more than the universally accepted attitudes, likely to change. If a person with a very conservative political attitude goes to a college where the prevailing intellectual climate happens to be liberal, his attitude will tend to change more and more in the liberal direction. In short, people are influenced by those with whom they associate.

The best evidence indicates that the mass communications

media, such as newspapers, radio and television, affect attitudes and opinions on occasions on which these media are all on one side of the issues and no dissenting voices are raised. On the other hand, when both sides of a matter are aired, these communications media seem to be very ineffective. There are several reasons for this. First, people tend to read newspapers and listen to speeches which agree with their own attitudes and opinions. Similarly, they tend to avoid exposing themselves to information and opinions which disagree with their own point of view. Second, when a person is exposed to information and opinions which disagree with his own, he has a strong tendency to talk about the matter with others who do agree with him. This process serves to obtain social support for his existing views, bolstering his attitudes and opinions. Third, when a person is exposed to disagreement via the mass communications media, it is usually possible for him to lessen the influence of this disagreement by regarding the source of the communication as less trustworthy than he had previously thought or as having some special hidden motive which has nothing to do with the truth of the matter. On controversial issues concerning strongly held attitudes, any influence the mass media may have is mediated through the face-to-face associations of the person.

The question of the relationship between attitudes and behaviour (*q.v.*) is complicated. It may be called reciprocal in that, on the one hand, attitudes affect and in part determine behaviour, and, on the other, behaviour will affect and partly determine attitudes. The ways in which attitudes affect behaviour are fairly clear. When the situation in which a person finds himself is relevant to a certain attitude which he holds, his behaviour will tend to be consistent with that attitude. Thus, for example, a person who has anti-intellectual attitudes is not likely to encourage his children to go to college. But the relationship would be very weak because other factors also enter into determining behaviour. The anti-intellectual parent might urge his children to go to college because this is a sign of status, because it is expected by others and because he recognizes that it will help his children get good jobs later in life. The attitude concerning intellectualism will be merely one among many factors which determine the specific behaviour.

Because attitude is only one of many determinants of behaviour, persons often engage in actions which are inconsistent with their attitudes. When such inconsistency exists, the person will make strong efforts to justify his actions to himself. In general, there are two major tendencies. First, the person may persuade himself that those factors which are consistent with his action are even more important than he had previously thought and find still more reasons, not previously thought of, which are consistent with the action. Second, he may change his attitude so that it corresponds more closely with his action, thus lessening the inconsistency. Thus, for example, a person who finds himself in a situation where, for one reason or another, he publicly espouses an opinion which is inconsistent with his privately held attitudes will, over time, change his attitudes somewhat to bring them more in line with the position he has taken publicly.

In general, however, by the time a person is adult many or most of his attitudes are well integrated and highly resistant to change. His associates tend to be persons who share his attitudes, and he tends to avoid situations which threaten them. In spite of the pressures on attitudes and the changes in them which do occur, the prevalent picture is one of stability.

This prevailing general stability permits questions to be raised concerning the relation between attitudes and other enduring personality characteristics. It is, however, difficult to distinguish between consistency among various attitudes and relations between attitudes and personality characteristics. The fact that there is consistency among attitudes is well documented. For example, people who are prejudiced against Negroes tend also to be prejudiced against other minority groups. But such people tend furthermore to have more "authoritarian personalities," and it is unclear whether the latter should be regarded as just another correlated attitude or as a correlated personality characteristic. Relations have been sought between attitudes and such personality characteristics as dominance, rigidity, dependency, tolerance of ambiguity and a host of others, but no clear and consistent relations have been discovered.

On the other hand, there are very clear relations between attitudes and such variables as intelligence, amount of education, socioeconomic level and age. More intelligence and more education usually go along with more liberal attitudes, while higher socioeconomic level and greater age are usually associated with more conservative attitudes. It is suspected, however, that these variables are not themselves directly causally related to the content of attitudes.

Variables such as level of education and socioeconomic status are probably indicative instead of the person's social milieu and pattern of activity, and these are probably the factors which directly influence attitudes.

ATTLEBORO, a city of Bristol county in southeastern Massachusetts, U.S., 12 mi. N.E. of Providence, R.I.

The area was part of the Rehoboth North purchase when John Woodcock began real settlement in 1669. The town was incorporated in 1694 and named for the English market town. In 1887 it was divided by the creation of the township of North Attleborough, also a manufacturing centre. Attleboro was incorporated as a city in 1914.

Industrial life began early with the founding of a jewelry business in 1780, a tannery in 1787 and a textile plant in 1801. The manufacture of jewelry, including costume jewelry, is the leading industry, along with the manufactures of silverware and plated ware.

Other substantial industries include the manufacture of scientific and controlling instruments, fabricated metal products and machinery.

For comparative population figures *see* table in MASSACHUSETTS: *Population*. (CA. M. C.)

ATTLEE, CLEMENT RICHARD ATTLEE, 1ST EARL (1883–) British statesman, was leader of the Labour party from 1935 to 1955, and prime minister from July 1945 to Oct. 1951.

He was born at Putney, London, on Jan. 3, 1883, the fourth son of a prosperous City solicitor and was educated at Haileybury college and University college, Oxford. After he left the university neither the shortage of money nor the bent of his talents forced him quickly into a career. He was called to the bar in 1906, but he practised little and in 1909 he abandoned the law. In 1905 he had begun regular visits to Haileybury house, a settlement in the poorest part of east London. In 1907 he took up residence there and, apart from his war service, the East End was his home until Jan. 1922. When he first went there he was a Conservative (although his father had been a Liberal), but the harsh poverty which he saw undermined his faith in the existing order. He did not undergo a sudden political conversion but his views moved steadily to the left. In 1907 he joined the Fabian society and in 1908 the Independent Labour party. From then onward he was a committed, ethical socialist.

© KARSH, OTTAWA

LORD ATTLEE

He was not a pacifist, however; and within two months of the outbreak of World War I he was commissioned in an infantry regiment. He served in Gallipoli, Mesopotamia and France, was severely wounded and attained the rank of major. On demobilization he returned to the East End and to social and local political work. He was defeated for the London County council in 1919 but when

the Labour party won control of the Stepney Borough council that year he was called in from outside to be mayor. In 1922 he was elected member of parliament for Limehouse and sat for that constituency until 1950. From 1950 to 1955 his constituency was West Walthamstow.

In the house of commons Attlee's progress was steady but in no way meteoric. In the first Labour government he was under-secretary of state for war. In 1927 he was appointed to the Indian Statutory commission, which accounted for his receiving no office on the foundation of the second Labour government. In 1930, however, he joined that government as chancellor of the duchy of Lancaster, a sinecure post which left him free to give wide-ranging assistance to the prime minister and other senior ministers. In March 1931 he was made postmaster general. When the government broke up a few months later Attlee showed no disposition to follow Ramsay MacDonald. On the contrary he reacted to the crisis of 1931 by moving left and for a year or two took a more cataclysmic view of social progress than was habitual with him.

At the general election of Oct. 1931, Attlee was one of the very few Labour leaders whose seats held firm. As a result he became deputy leader of the party under George Lansbury. In 1935 Lansbury resigned and Attlee succeeded to the leadership. The general election of that year resulted in the return to the house of commons of several figures who, had they been members of the previous parliament, would probably have been preferred to Attlee. They did not, however, succeed in replacing him as leader. In a contested election he secured 58 votes, Herbert Morrison 44, and Arthur Greenwood 32. A second ballot gave Attlee 88 against Morrison's 44. His leadership was never again challenged to a vote.

During the late 1930s Attlee led his party toward a moderate home policy (symbolized by the adoption of the "immediate program" in 1937) and resistance to fascism and aggression abroad (tempered by a reluctance to accept rearmament). He gave his full support to the British declaration of war in 1939, but was unwilling to join a government under Neville Chamberlain. In May 1940, it became impossible for Chamberlain to carry on without bipartisan support and Attlee's attitude was decisive in forcing his replacement by Churchill. Attlee then entered the war cabinet as lord privy seal. In 1942 he became deputy prime minister and secretary of state for dominion affairs. In 1943 he became lord president of the council, though retaining the deputy premiership, and served in this capacity until the end of the war. Only he and Churchill served continuously in the war cabinet throughout the life of the coalition government.

In May 1945 Attlee led his party out of the coalition and achieved a great parliamentary majority at the general election which followed. He became prime minister on July 26 and held this office until Oct. 1951—a longer continuous period than any man since Asquith. The government over which Attlee presided was notable for its social legislation, including the establishment of the national health and national insurance schemes, for its extensive measures of nationalization and for the granting of independence to India. With this last decision Attlee himself was particularly closely associated.

Several of Attlee's principal colleagues—notably Ernest Bevin, Stafford Cripps and Herbert Morrison—were more dominant public personalities than he was, but he held the government together with great success and was reputed to exercise a firm control in cabinet. He gave unfailing support to Ernest Bevin's policy of building up the strength of the west and in 1950 he readily accepted the need both for armed intervention in Korea and for the launching of a big rearmament program. By this time his parliamentary majority had been reduced in the general election of Feb. 1950 to the tight margin of six. In April 1951 the government was further weakened by the resignation of Aneurin Bevan and Harold Wilson, and in the autumn of that year Attlee decided to ask for a dissolution of parliament. The subsequent general election resulted in a narrow Conservative victory and Attlee's resignation as prime minister.

He remained leader of the opposition until Nov. 1955, endeavouring to preserve the unity of his party throughout the difficult days of the "Bevanite" quarrel and leading it in the unsuccessful election campaign of May 1955. On his resignation from leadership of the Labour party he was created an earl; he had been made a knight of the order of the Garter in 1956. In 1954 he published a volume of memoirs, *As It Happened.* (R. J.)

ATTORNEY: *see* LEGAL PROFESSION.

ATTORNEY GENERAL. A governmental official found in nearly every country in which the legal system of England has taken root. Briefly defined, the attorney general is the chief law officer of the state or nation and the legal adviser to the chief executive.

UNITED STATES

The attorney general of the United States is the chief law officer of the government and head of the department of justice, one of the executive departments. He is appointed by the president and is a member of the cabinet. In case of death, resignation, removal or disability of both the president and the vice-president, he is in line of succession to the presidency, after the speaker of the house of representatives, president pro tempore of the senate, secretary of state, secretary of the treasury and secretary of defense.

The office of attorney general of the United States was created by the Judiciary act of 1789. This act divided the United States into 13 judicial districts, established courts therein, defined their jurisdiction and also the appellate jurisdiction of the supreme court. The act provided that in each district there should be an attorney for the United States who should have charge of civil and criminal actions in his district, and finally that there should be appointed an attorney general of the United States who was to be "a meet person learned in the law," whose duty it should be to represent the United States in the supreme court and who should be the legal adviser of the president and of the heads of the departments "touching any matters that may concern their departments." The attorney general, under this act, was not an executive officer of the government. His duties, as defined by the statute, made him merely an adviser of the executive branch and an advocate in the supreme court, and the measure of his compensation, $1,500 a year, was based upon the belief that his duties would take but little of his time, leaving him free to enjoy the professional emoluments which it was thought the prestige of his position would bring him. Until about the year 1814, the attorney general did not reside at the seat of government. In that year, Atty. Gen. William Pinkney, one of the great lawyers of his day, resigned because Pres. James Madison insisted that he take up his residence in Washington. From the beginning, however, the office was regarded as one of great dignity and importance, and with the growth of the United States and the development of its governmental functions statutes were enacted from time to time which increased its duties and responsibilities, and gradually brought it to a parity with the heads of the executive departments. In 1870 it was organized by law as the department of justice.

The department of justice is an executive department and the attorney general as its head has plenary control over the law business of the government, all its other law officers being subordinate to him, though most departments, bureaus and commissions of the federal government have lawyers on their staffs who are not officers or employees of the department of justice and who, in the performance of their duties within their respective departments, are not under the specific direction of the attorney general. In the language of the U.S. supreme court he "has charge of the institution and conduct of the pleas of the United States and of the litigation which is necessary to establish the rights of the Government."

The duties of the attorney general are primarily those of a lawyer, but as head of the department much of his time and energy must be devoted to administration. His chief assistant is the deputy attorney general, who by law exercises the powers of attorney general in the latter's absence and is the department's chief liaison officer with congress and other government agencies. The solicitor general has charge of the government's litigation in the

supreme court and decides, after consultation with the attorney general in cases of particular importance, whether review in the higher courts shall be sought in cases which the government has lost in courts below. This duty of passing upon questions of appeal and therein seeing to it that the government's interests are protected and all reasonable effort made to procure a correct construction of the law, at the same time avoiding imposing unwarranted burdens upon the appellate courts and unnecessary expense to litigants, is one of grave responsibility, calling for the exercise of sound, discriminating judgment.

There are also ten assistant attorneys general, among whom supervision of the other work of the department is principally apportioned. Each assistant attorney general has charge of one of the department's eight divisions—antitrust, civil, civil rights, criminal, internal security, lands, tax, administrative—or the office of legal counsel or the office of alien property. In addition a United States attorney is appointed by the executive for each of the federal district courts and, except for matters assigned to other department attorneys, represents the U.S. government in litigation arising in that district.

The number of federal district courts has increased from the original 13 to 91, including Alaska and Hawaii, each having one or more district judges. There is a court of appeals, composed of three to nine circuit judges, for each of the 11 circuits (including the District of Columbia as a circuit). In 1855 there was established a court of claims (*see* Petition of Right: *Proceedings Against the State in the United States*).

The Federal Bureau of Investigation is one of the bureaus of the department of justice. The FBI investigates all violations of federal criminal statutes with the exception of those assigned by law to the department of the treasury, including income and liquor taxes, smuggling, counterfeiting and narcotics violations and, in addition, the security of the president and vice-president, this duty being the task of the secret service, an agency of the treasury. Under an executive order of the president the FBI is given sole responsibility for the handling of matters pertaining to the general internal security of the nation. The order directs that all information relating thereto be reported to it.

Through the director of the bureau of prisons the attorney general controls all federal prisons and prisoners.

The administrative control and supervision of the offices of U.S. marshals are in the attorney general. All petitions to the president for pardon, commutation of sentence or other form of executive clemency are investigated by an official of the department called the pardon attorney, and the facts relating to each application are ascertained for the guidance of the attorney general in making his recommendation to the president. The attorney general also makes recommendations to the president respecting appointments to all federal judicial positions, including the U.S. supreme court.

As already pointed out, from the beginning the attorney general has been the legal adviser of the president and of the heads of the executive departments with respect to the questions arising in the administration of their departments. For many years pursuant to statute his formal opinions have been published from time to time in book form. They generally control the action of the executive officers of the government, are frequently cited by the courts and regarded as of high authority. Prepared under statutory sanction by the chief law officer of the government for the guidance of the heads of departments charged with the administration of the statutes enacted by congress, they have the status of important state papers entitled to the highest respect upon all questions of the powers and duties of the executive branch of the government. For the names and terms of service of U.S. attorneys general, *see* Cabinet.

There is also under each state government an officer, usually called the attorney general, whose relation to the government of his state is similar to that of the U.S. attorney general to the federal government. He is usually elected by the people at the same time and for the same term as the governor. For an accurate description of the duties of the attorney general of any particular state an examination of the constitution and laws of that state is necessary. *See* also Legal Profession.

ENGLAND AND WALES

In England and Wales, the attorney general is the senior law officer of the crown. He is assisted by the solicitor general, who is subject to his authority but has otherwise the same rights and duties. The law officers have a small department, staffed by professional civil servants (who are also barristers). Functions in many respects similar to those of the English law officers are performed by the lord advocate and solicitor general for Scotland and by the attorney general for Northern Ireland.

The attorney general, who is the crown's representative in courts of law and the legal adviser of the sovereign and the sovereign's ministers, is a member of the government (but not, nowadays, of the cabinet). He is consulted on the drafting of all government bills, advises government departments on matters of law and has a wide range of duties in relation to the courts. The attorney general is invariably a member of the house of commons; he is answerable to the house for the exercise of his ministerial duties; he has a right to address all its standing committees; and he deals in the house with all matters, including law reform bills, which lie within the province of the lord chancellor.

The office of attorney general dates from the middle ages but did not begin to assume its modern form before the 16th century. The medieval attorney was not a barrister but merely the representative of his client in legal proceedings and, for the crown's business, "king's attorneys" were at first appointed only for particular business or for particular cases or courts. The issue of a patent in 1399 to William de Lodington as "King's Attorney in the Common Bench and all other places" may be regarded as the first appointment of an attorney general for the crown. In time he acquired the right to appoint deputies and became something like a permanent official with a staff of assistants. However, the right of audience before the medieval courts was the exclusive privilege of barristers and, when the office of attorney general became too important to be held by a mere attorney, it was from the barristers that he came to be appointed and whose leadership he eventually assumed. As the medieval system broke down and new courts and new political institutions were set up, there was a marked increase in the influence of the law officers, which has been characterized by one writer as a "phenomenon of the same kind as the rise in the political sphere of the King's Secretaries at the expense of many older medieval functionaries." At the beginning of the 17th century the office of attorney general was held by men of the calibre of Edward Coke and Francis Bacon; the position of the law officers as legal advisers to the crown had become established and they conducted state prosecutions and defended the royal interests in parliament. However, the link with parliament came first through the attorney general's attendance on the house of lords, to which the law officers were summoned with the judges as assistants in matters of law; and it was the solicitor general who first acquired a seat in the commons. The attorney general, for long being the traditional upholder of the king's prerogative, remained suspect with the commons as an instrument of the royal influence in parliament; not until after the Restoration did it become normal for him to be a member of the house of commons.

The attorney general still exercises many of his historic functions as legal adviser to the sovereign. He advises on petitions claiming peerages that are dormant or in abeyance, reports on applications for royal licences to hold land in mortmain, makes recommendations for the disposition under the sovereign's hand of certain property bequeathed for charitable purposes and examines the drafts of royal charters. It is because he is the representative of the sovereign as *parens patriae* (the liege lord and

protector of subjects) that legal proceedings to enforce public rights (such as public rights of way) and proceedings on behalf of the interests of charity are conducted in his name. It is also by virtue of his office as a law officer of the crown that the attorney general is recognized by the bar as the leader of the profession.

The greater part of the law officers' work today, however, is, apart from their parliamentary duties, that of counsel for the crown in a wider sense. The modern departments of state have their own legal staffs, but the law officers are responsible for the legal advice given to the government, and it is to the law officers that departments turn for advice on matters of particular difficulty or of political or national importance. The law officers continue to practise as barristers while they are in office, although the crown is their only client and their fees take the form of an annual salary, and they appear personally in court, where they take precedence over all other barristers, in cases particularly affecting the rights and interests of the crown. It is also the custom for a law officer to represent the United Kingdom before such tribunals as the International Court of Justice.

Although the attorney general is a minister of the crown, he exercises the majority of his functions in a quasi-judicial manner and without regard to political considerations of any kind. In modern times there has been a tendency to add functions of this kind to his duties; for example, at public inquiries into aircraft accidents he represents the interests of the general public as distinct from the interests of any government department which may be involved. But perhaps the most significant modern development in this field has been in relation to the criminal law. Before the 19th century it was the invariable rule in England and Wales that criminal prosecutions were instituted not in the name of the state but by private individuals, "public" prosecutions being instituted by officials in their private capacity. In practice, all prosecutions for such offenses against the state as treason and sedition were instituted on behalf of the crown in the name of the attorney general; and the harsh and oppressive manner in which this function was exercised exposed the law officers to such general opprobrium and suspicion that parliament would certainly have resisted any attempt to centralize the control of prosecutions in their hands. In the 19th century, however, the rigidity of the general rule about private prosecutions was undermined. First, the development of police forces resulted in a marked decrease in the number of prosecutions instituted by the ordinary citizen; second, parliament found it necessary to take steps (such as the enactment of the Vexatious Indictments act, 1859) to restrict some of the liberties of the private prosecutor; and third the law officers began to conduct themselves less as servants of the executive than as independent officers of state. When, therefore, in 1879 the Prosecution of Offences act created the office of director of public prosecutions with the primary duty of advising on and, where necessary, taking over the conduct of prosecutions, it was natural that he should be placed under the general superintendence of the attorney general; and there are in the second half of the 20th century over 50 offenses created by act of parliament for which prosecutions can be instituted only with the consent of either the attorney general or the director of public prosecutions.

The attorney general also has a right to stay criminal proceedings in the superior courts. This power, which is not subject in any way to review by the courts, is in modern times used almost (but not quite) exclusively to dispose of proceedings against persons who are, and are likely to remain, for medical reasons unable to stand their trial.

Although the attorney general is a minister and the director of public prosecutions is a civil servant, the administration of the criminal law is conducted without interference from the government of the day and independently of party political pressure; indeed, in 1924 the mere allegation that a prosecution (in the famous Campbell case) had been withdrawn on the instructions of the attorney general under pressure from the cabinet was the immediate occasion of a vote of censure which brought down the government. It is now established that, subject to the attorney general's right and duty to consult his ministerial colleagues on the likely consequences of a particular prosecution, he exercises his duties in the enforcement of the law free of governmental control or political pressure.

Bibliography.—For the history of the office *see* W. S. Holdsworth, *A History of English Law*, vol. vi (1924); T. F. T. Plucknett, *A Concise History of the Common Law* (1929); H. J. Cohen, *A History of the English Bar*, etc. (1929); G. R. Y. Radcliffe and G. N. Cross, *The English Legal System* (1954); H. H. L. Bellot, "The Origin of the Attorney-General" in *The Law Quarterly Review*, vol. xxv (1909); G. W. Keeton, "The Office of Attorney-General" in *The Juridical Review*, vol. lviii, no. 2 and 3. The best modern descriptions of the office of the attorney general are to be found in the address delivered by Sir Hartley Shawcross to the Law Society on Feb. 18, 1953, and in Lord MacDermott, *Protection from Power Under English Law*, chap. 2 (1957). There is also a valuable chapter in G. W. Keeton, *A Liberal Attorney-General* (1949). The statement of the attorney general's position in connection with prosecutions in the House of Commons Official Report for Jan. 29, 1951 (Sir Hartley Shawcross) is authoritative. (D.)

ATTRIBUTES, in philosophy, insofar as they are not simply predicates, are either the qualities ascribed to a substance beyond the finite mind's powers of definition (as theologians speak of the attributes of God) or properties recognized as necessarily consequent from the essence of a substance. *See* Predicables; Qualities; Substance; also Spinoza, Benedictus de.

ATTWOOD, THOMAS (1783–1856), English political reformer and writer on economics, was born at Halesowen, Worcestershire, Oct. 6, 1783. A country banker by occupation, connected with the local iron industry, he was high bailiff of Birmingham in 1811. From that year on he was preoccupied with currency questions. When successive governments refused to accept the ideas which he advocated in his pamphlets and in 1819 the decision was taken to return to the gold standard, Attwood became increasingly radical in his political outlook. The prevalence of economic distress, particularly after 1826, encouraged him to set up a new political organization to bring pressure on the government. In Dec. 1829 he founded the Birmingham Political union to demand parliamentary reform as a means of securing currency reform. Its structure and methods were copied in many other parts of the country. After the passing of the Reform act in 1832 he was elected a member for the new borough of Birmingham, for which he sat until 1839. Inside and outside the house of commons he advocated that national currency based on a gold standard should be replaced by state-regulated paper money, the volume of which should be determined by the level of employment. Although at the time his views were considered heretical, they were influential in the midlands and have since been considered more plausible and interesting than the classical economists maintained. He died at Great Malvern, March 6, 1856. (A. Bri.)

AUBADE, music sung or played at dawn as opposed to serenade (evening music). The form originated in Provence where it was known as the *alba*, the earliest known manuscript being an anonymous *alba bilingua* in Latin and Provençal. In the 12th and 13th centuries the Provençal *alba* was the warning-song sung to lovers at dawn by a watchman (*see* Troubadours). Examples are the anonymous *Gaite de la tor* and *Reis glorios* by Guiraut de Bornelh. The later German form of the *alba* was the *Tagelied*. In the 19th and 20th centuries the term aubade was used in a more general sense to describe morning music as is shown by the aubade in Edouard Lalo's opera *Le Roi d'Ys* and by Sir Arthur Bliss's *Aubade for Coronation Morning*. In France the term is also used to describe music played at dawn in honour of distinguished people.

AUBE, a *département* of France, is situated southeast of Paris in the ancient province of Champagne (*q.v.*). Area 2,317 sq.mi. Pop. (1962) 255,099. It is bounded north by Marne, east by Haute-Marne, southeast by Cote d'Or, southwest by Yonne, and northwest by Seine-et-Marne. The *département* is traversed from southeast to northwest by the converging valleys of the Aube and Seine rivers, crossing the dry chalk platform of Champagne. Beyond a low escarpment that forms the southeastern edge of the chalk outcrop is a belt of damp, undulating clay country, with pastures and woods. The ground rises southeastward again toward the scarped limestone hills that are known as the Côte des Bars, with Bar-sur-Aube and Bar-sur-Seine in the river gaps. In the western part of the *département* a capping of sands and clays overlies the chalk and gives a damper surface and more

varied relief in the Forêt d'Othe.

The bare chalk platforms were long of little use except for sheep grazing, but have been improved for agriculture since the middle of the 19th century. They are sparsely inhabited and most of the population lives in the well-watered valleys. Champagne lay on important trade routes in the middle ages and was famous in the 12th and 13th centuries for its great fairs, especially at its capital, Troyes (*q.v.*), in the valley of the Seine. The woolen industry rose to importance, but suffered eclipse later. After stagnating during the 17th and 18th centuries Troyes was revived by the modern development of the hosiery and knitwear industry, using cotton and later rayon and man-made fibres. Hosiery factories are widespread in the *département*, but Troyes (pop. [1962] 67,074) is the chief centre of the industry, and has important associated engineering works. The woolen industry survives chiefly in the Pays d'Othe.

The *département*, which is centred upon Troyes, is divided into the *arrondissements* of Troyes, Bar-sur-Aube and Nogent-sur-Seine. The bishopric of Troyes lies in the archbishopric of Sens. In the southeastern corner of the *département*, in the Aube valley, is the historic abbey of Clairvaux (*q.v.*). For educational organization the *département* lies in the *académie* of Dijon, and its court of appeal is at Paris. (Ar. E. S.)

AUBE RIVER, in east-central France, is a tributary of the Seine river which it joins above Romilly. The Aube and its tributary the Aujon rise on the Langres plateau and flow northwestward for 154 mi. in trenchlike valleys across the dry oölitic limestone country. By Montigny-le-Roi and Châteauvillain respectively the valleys open as they traverse the clay depression in front of the broken corallian limestone escarpment known as the Côte des Bars. The Aujon joins the Aube at Clairvaux as the rivers enter the *département* to which the Aube gives its name, and the valley is again trenchlike about Bar-sur-Aube as it cuts across the limestone outcrop. It opens out again and the river receives many small tributaries in crossing the Lower Cretaceous clay country toward Brienne. From Brienne to its confluence with the Seine the valley of the Aube, curving west past Arcis-sur-Aube, is a flat strip of alluvium set within the dry chalk platform of Champagne, and the river receives few surface tributaries. (Ar. E. S.)

AUBER, DANIEL FRANÇOIS ESPRIT (1782–1871), French opera composer who was one of the principal figures in the development of the *opéra-comique* in the first half of the 19th century. Born, Jan. 29, 1782, at Caen, he composed instinctively as a child, and later became a pupil of Luigi Cherubini. His first publicly performed dramatic work was the one-act *Le Séjour militaire* (1813). This was followed by *Le Testament et les billets-doux* (1819). Neither was remarkable. Auber's contribution to *opéra-comique* derived partly from his association with Eugène Scribe who, with A. H. J. Mélesville, wrote the libretto, based on Walter Scott's *Kenilworth*, of *Leicester, ou le Château de Kenilworth* (1823), and partly from the impact made on French music by Rossini. Scribe's librettos, constructed with an infallible sense of the theatre, offered an ideal framework for the romantic type of *opéra-comique* to be cultivated by Auber, while the vivacious works of Rossini provided him with a musical style readily adaptable to French operatic taste. Between 1823 and 1864, 38 dramatic works of Auber on librettos of Scribe were produced in Paris. Most were *opéras-comiques*, of which the most successful were *Le Maçon* (1825), *La Fiancée* (1829), *Fra Diavolo* (1830), *Le Domino noir* (1837) and *Les Diamants de la couronne* (1841). Rossini's tribute to their lively style, "*petite musique mais d'un grand musicien*," is still valid.

The romantic vein explored by Auber and Scribe was also suited to grand opera and several of their works, including *La Muette de Portici* (1828, also known as *Masaniello*), *Le Philtre* (1831), *Le Serment* (1832) and *Gustave III* (1833), anticipated the operas of Meyerbeer. Further evidence of this link with romantic opera is seen in the fact that the librettos of *Le Philtre* and *Gustave III* were adapted for Donizetti's *L'elisir d'amore* and Verdi's *Ballo in Maschera*.

Auber's life, almost entirely devoted to opera, was uneventful. His religious music, consisting of motets and cantatas written between 1852 and 1855, is little known. He was elected a member of the Academie Française in 1829, and appointed director of the Paris Conservatoire in 1842 and chapel master to Napoleon III in 1857. He died in Paris, May 12, 1871. Though few of his works were revived, his influence, recognized by both Wagner and Richard Strauss, was wide, extending to the early works of Gounod and Massenet.

AUBERGINE: *see* EGGPLANT.

AUBERVILLIERS, a town in northern France in the *département* of Seine, lies 4 mi. (6 km.) N.N.E. of Paris on the St. Denis canal. Pop. (1962) 70,592. Its church of Notre-Dame-des-Vertus (15th–16th centuries) recalls that it was an important place of pilgrimage from the 14th century. Its chief industry was the provision of vegetables for consumption in Paris but now, although market gardening continues, Aubervilliers has become an industrial complex. Chemical products predominate including tallow, artificial manure, paints, varnishes, matches and perfumes. (H. DE S.-R.)

AUBIGNAC, FRANÇOIS HÉDELIN, ABBÉ D' (1604–1676), French critic who played an important role in literary discussions of the 1640s and the 1660s, was born in Paris, Aug. 4, 1604. Attached to Richelieu, he furthered the cardinal's efforts to improve the status of drama. He wrote plays, three of which are extant, in prose (*Cyminde, La Pucelle d'Orléans*, both published 1642, *Zenobie*, 1647). The abbé's polemical writings fall into three groups: two essays against Ménage (1640, 1656); four essays in criticism of plays of Corneille, written in 1663–64; and a study of dramatic technique, *La Pratique du théâtre*, commissioned by the cardinal, but abandoned after his death, and published only in 1657. It is referred to by Corneille and Racine, but had no wide appeal. D'Aubignac also wrote allegorical pieces and a dissertation on Homer. He lived in Paris until after the Fronde. Recent research shows him associated with the coteries concerned in *Les Précieuses ridicules*. He died in Nemours, July 25, 1676.

La Pratique du théâtre, written in a period of lively critical polemic, is a systematic treatment of the elements of playmaking. Long thought to be a codification of French classical doctrine it does not actually define the unities, but insists on credibility (or *vraisemblance*) in the eyes of the audience as the guiding principle. It is therefore an excellent indirect testimony to the taste of the French theatre-going public. The abbé insists, presumably because the public did, on the dramatic illusion being as complete as possible. That illusion is broken if, for instance, actors call for silence or if the audience without changing their own position are asked to imagine a change of scene. The illusion is the greater if the subject be presented as near to its crisis as possible, if the number of actors be such that no confusion (a key word) be left in the minds of the audience as to what is happening, if the speeches in the play be dramatic rather than rhetorical. All this is presented with a mass of quotations from Aristotle and ancient Greek drama, on the assumption that reason and respect for the classics were almost one and the same. Despite the work's small sale it was probably a notable force in the formation of French classical taste. It makes many points which Corneille and Racine were to put into practice, and this in spite of the fact that d'Aubignac has no grasp of poetic tragedy nor of the comedy which Molière was creating under his nose. The *Pratique* indeed avoids major aesthetic questions and modestly keeps to the means and methods of dramatic workmanship. D'Aubignac, however, states repeatedly his admiration for Corneille. It is ironical that, soured by later polemic he scored out, in a copy still preserved, all favourable references to Corneille, but that this copy was unknown to the publisher of the second edition, in 1715.

AUBIGNÉ, THEODORE AGRIPPA D' (1552–1630)

major French poet of the late 16th century and also renowned as a Huguenot captain and polemicist and historian of his own times, was born near Pons in Saintonge on Feb. 8, 1552. After a strenuously studious youth in Paris, Orléans, Geneva and Lyons, he escaped from his guardian's house at 16 to join the Huguenot forces, and served throughout the Wars of Religion on the battlefield and in the council chamber. He was *écuyer* ("master of horse") to Henry of Navarre. After Henry's accession to the French throne as Henry IV and his abjuration of Protestantism, Aubigné withdrew to his estates in Poitou. Under the regency of Marie de Médicis, his intransigence estranged him from his Huguenot brethren. Proscribed in 1620, he took refuge in Geneva, where he remained until his death on April 29, 1630. His closing years were clouded by the scandalous conduct of his son Constant—father of Françoise d'Aubigné, later Madame de Maintenon.

Among Aubigné's prose works, the *Confession catholique du sieur de Sancy*, first published in 1660, is a parody, ironically dedicated to Cardinal du Perron, of the tortuous explanations offered by Protestants who followed Henry IV's example of abjuration. His comment on life and manners ranges more widely in the *Aventures du baron de Faeneste* (1617) in which the Gascon Faeneste represents attachment to outward show (*le Paraître*), while honest squire Énay, embodying the opposite principle (*l'Être*), tries to clear Faeneste's mind of cant. The *Histoire universelle*, so called because it treats not only of France, but also, more schematically, of Europe at large, deals with the period from 1553 to 1602, with an appendix to cover the death of Henry IV (1610); an unfinished supplement was meant to bring the story down to 1622. Despite its author's conscientious documentation and sincere effort to achieve historical detachment, the interest of the *Histoire* lies chiefly in its many eyewitness accounts and in the liveliness of Aubigné's writing.

His major poem, in seven cantos, the *Tragiques*, begun in 1577 and published only in 1616, celebrates the justice of God, who in the Great Doom will gloriously avenge his slaughtered saints. The nature of the subject matter and the sectarian bias, besides serious faults of composition and expression, account for the almost complete neglect of the poem until C. A. Sainte-Beuve called attention to it in 1828. But there are many passages of great poetic power, realistic or satirical, elegiac or apocalyptic; while the scope of the design, extending from the hovel of the tortured peasant to the courts of Heaven, confers an extraordinary grandeur on the work. Modern research on the baroque in literature has awakened interest also in Aubigné's youthful love poetry, collected in the *Printemps*, written for Diane Salviati, a niece of Pierre de Ronsard's Cassandre. It remained in manuscript until 1874. In this, the traditional figures of the pseudo-Petrarchan manner then current are transmuted into a highly personal style, full of tragic resonances, by Aubigné's characteristic vehemence of passion and force of imagination.

Aubigné's works have been published as follows: *Oeuvres complètes* (excluding the *Histoire universelle*), edited by E. Réaume and F. de Caussade (1873–92); another edition, including the *Histoire universelle*, by A. de Ruble (1886–1909); the *Supplément*, edited by J. Plattard (1925); the *Printemps*, edited by B. Gagnebin (first part, 1948) and F. Desonay (second part, 1952); and the *Tragiques*, edited by A. Garnier and J. Plattard (1932).

(A. J. St.)

AUBREY, JOHN (1626–1697), English antiquary, best known for the pen portraits of contemporaries which he wrote for Anthony à Wood's *Athenae Oxonienses* and which were later published as *Lives of Eminent Men*, was born on March 12, 1626, at Easton Pierse, Wiltshire. His father was a country gentleman with estates in Wiltshire, Herefordshire and south Wales which Aubrey inherited in 1652. Aubrey had spent some years in Oxford as an undergraduate at Trinity college, and in London as a student of the Middle Temple, and had already displayed his taste for antiquities by calling attention to the prehistoric stones at Avebury, Wiltshire. His literary and scientific interests won him a fellowship of the Royal society in 1663. Meanwhile he had been traveling in England and visiting the continent, distracted by a series of love-suits and lawsuits which he refers to in his diary with a naïveté made the more disarming by his ingenuous belief in the influence of his own horoscope. "I was never riotous or prodigall," he says, "but . . . sloath and carelessness are equivalent to all other vices." He spent much time in "delitescence," avoiding creditors and enjoying the hospitality of friends in the country. He was never free from lawsuits until in 1670 he sold what was then left of his estates. He never married.

In 1667 Aubrey met Anthony à Wood (*q.v.*), and his antiquarian zeal was thenceforward devoted largely to supplying material for Wood's *Athenae Oxonienses*. He also collected material for his own *The Natural History and Antiquities of . . . Surrey* (pub. 1719) and *The Natural History of Wiltshire* (pub. 1847), but his main legacy to posterity was *Lives of Eminent Men*, on which Wood drew extensively. Extracts were published in two volumes (1813), but the definitive presentation of Aubrey, as a man and as a biographer, is Andrew Clark's edition, *Brief Lives* (2 vol., 1898). The editor omits some coarse passages, but the text gives a series of vivid and intimate (and sometimes acid) portraits of his contemporaries and a delightful impression of the whimsical and easygoing author himself.

Aubrey's only work published in his lifetime was *Miscellanies* (1696), a collection of stories of apparitions and curiosities. He had an eye for the odd and the picturesque, particularly in human behaviour and characteristics, but no power of organizing his material or planning a major work. His easy and equable temper won him many friends, among whom were Elias Ashmole, Sir Christopher Wren, Robert Hooke, Thomas Hobbes, Sir William Petty and Bishop Seth Ward, besides Wood and Bishop Tanner, to whom he made over much of his manuscript collections. In his later years, Aubrey considered emigrating to North America or the West Indies to take up grants of land with which his patrons offered to relieve his financial straits. But he never left England, and died while passing through Oxford in June 1697.

BIBLIOGRAPHY.—A *Memoir* by J. Britton appeared in 1845. A more lively account is given by Anthony Powell, *John Aubrey and his Friends* (1948), and a comprehensive selection from his biographical manuscripts was edited by O. L. Dick (1949). (J. Sp.)

AUBRIETIA, a genus of about 12 species of small, perennial, ornamental herbs of the family Cruciferae (*q.v.*), found in the mountains from Italy to Iran. The chief cultivated species is the purple rock cress (*A. deltoidea*), found from Sicily to Asia Minor. It is a prostrate, mat-forming perennial with small leaves and showy, four-petaled, purple or violet flowers. Over 40 horticultural forms of it are grown as ornamentals, having variously coloured and sometimes double flowers. All are best grown in the rock garden, in full sunshine and in a gritty or sandy loam that is not acid. (N. Tr.)

AUBURN, a city of southwestern Maine, U.S., on the Androscoggin river opposite Lewiston, 32 mi. N.E. of Portland; seat of Androscoggin county. The manufacture of shoes is the city's chief industry. With Lewiston, it forms an important industrial centre favoured by abundant water power. Auburn's large area, 66 sq.mi., includes four bathing beaches and other recreational facilities; and Taylor pond, a resort area, and Lake Auburn, source of the water supply for both municipalities, are within the city limits.

Settled in 1786, Auburn was incorporated as a town in 1842, rechartered as a city in 1869, and in 1917 was the first Maine city to adopt council-manager government. Pop. (1960) city, 24,449; Lewiston-Auburn standard metropolitan statistical area (Lewiston, Auburn, Lisbon town), 70,295. For comparative population figures *see* table in MAINE: *Population*. (Ro. Be.)

AUBURN, seat of Cayuga county, N.Y., U.S., in the heart of the Finger Lakes district, 25 mi. S.W. of Syracuse, on an outlet of Owasco lake, which lies 2 mi. S.E. (For comparative population figures *see* table in NEW YORK: *Population*.)

The manufacture of stationary and marine diesel engines is one

of the city's chief industrial enterprises. Other industries include the manufactures of molded plastics, rope, women's shoes, carpets and electronic components. The city is a centre of truck transportation.

The Auburn Theological seminary, chartered in 1819, was located there until 1939 when it merged with Union Theological seminary at New York city. The Seymour (public) library is housed in the Case Memorial building. The Auburn Community college, administered jointly by the Auburn board of education and the State University of New York, was founded in 1953.

The Auburn state prison, when it was built in 1816, embodied advanced ideas of prison construction and the Auburn system (solitary confinement by night, work in association during the day) received much attention from the penologists of Europe and the United States (*see* PRISON: *Silent System*). The hiring of prison labourers at low rates, a practice which was not abolished until 1882, attracted a number of industries in the 19th century.

Auburn was founded in 1793 by Col. John L. Hardenbergh on the site of a Cayuga village called Wasco, near the place where the Genesee trail crossed the outlet of the lake, and was first called Hardenbergh Corners. In 1805 it became the county seat and was incorporated in 1815. It was chartered as a city in 1848, and in 1920 adopted the commission-manager form of government.

On the summit of Fort Hill—once a stronghold of the Cayuga Indians—in the southwestern part of the city is a grass-grown earthwork on which stands a monument to the Cayuga leader Logan (b. 1725), an unswerving friend of the early settlers of the region. Auburn was the home of William H. Seward, Abraham Lincoln's secretary of state, and Enos Thompson Throop (1784–1874) who was the 12th governor of New York (1829–33). (V. C. C.)

AUBUSSON, PIERRE D' (1423–1503), grand master of the order of St. John of Jerusalem, famous for his defense of Rhodes against the Turks, was born of a noble French family. Very early in life he served the Austrians as a soldier of fortune against the Turks in Hungary. On his return to France, he became the friend of Charles VII's son, the dauphin Louis, whom he succeeded in making more obedient to his father. About the time of the fall of Constantinople to the Turks (1453) Aubusson joined the order of St. John of Jerusalem and in 1476 became grand master. The defense of Rhodes against the fleet of the sultan Mohammed II in 1480 made him famous throughout Europe. Later, however, when Jem, brother of Mohammed's successor Bayazid II (*q.v.*), took refuge in Rhodes, the grand master, though he had given Jem a safe conduct, nevertheless accepted a bribe from Bayazid and imprisoned Jem for six years and then handed him over to Pope Innocent VIII. Aubusson's reward was a cardinal's hat (1489) and the power to confer all benefices connected with the order without the sanction of the papacy. Subsequently he did much to restore discipline and zeal in his order and to strengthen its authority in Rhodes. He extirpated Judaism in the island by expelling all adult Jews and forcibly baptizing their children. He also tried to organize a large international crusade against the Turks, but in 1501, when he led an expedition against Mytilene, dissensions among his motley host rendered it abortive. His last years were embittered by chagrin. He died on July 3, 1503.

See D. Bouhours, *Histoire de Pierre d'Aubusson* (1676, 4th ed. 1806; extracts several times reprinted in the 19th century); G. E. Streck, *Pierre d'Aubusson . . .* (1872); and general histories of the order of St. John of Jerusalem. (MI. M.)

AUBUSSON, a market town in central France, lies on the Creuse river in the *département* of that name, 59 mi. N.W. of Clermont-Ferrand by road. Situated at 1,430 ft. it is near the northern edge of the plateau of Millevaches, the highest part of the Monts du Limousin. Pop. (1962) 5,343. Aubusson is famous for its manufacture of tapestries and carpets which employs more than 2,000 people. The industry dates back at least to the 16th century, and artistic standards are maintained by a national school of decorative arts, founded in 1869. Beauvais and Gobelins tapestries are still made there on handlooms. In the middle ages Aubusson was the centre of a viscounty; from the family of the viscounts was descended Pierre d'Aubusson (*q.v.*). (AR. E. S.)

AUCASSIN AND NICOLETTE, an early 13th-century *chantefable,* a story told in alternating sections of verse and prose, the former sung, the latter recited. It is considered by some to have Moorish and Byzantine sources.

Aucassin, son of Count Garin of Beaucaire, is in love with Nicolette, a converted Saracen slave who later proves to be the daughter of the king of Carthage(na). To keep them apart both are imprisoned, but Nicolette escapes and Aucassin, when released, joins her in the forest. They flee to Torelore (Aiguesmortes) and remain there for three years until captured by Saracens and carried off in two ships which are separated by a storm. Aucassin's ship is conveniently wrecked off Beaucaire (then a port) and, his parents being dead, he becomes count. Nicolette is taken to Carthagena and is recognized by her father. When, however, he wishes her to marry, she disguises herself as a minstrel, takes ship, returns to Beaucaire and marries Aucassin.

This work is known in a late 13th-century manuscript (Bibliothèque Nationale, fonds fr. 2168) with marked northeastern characteristics. Its northern French author excels in the depiction of youthful love, but reveals little taste for pure narration. He shows strong artistic and musical talent, a tendency to playful mockery and much human sympathy. While Nicolette is full of resourcefulness, Aucassin, "endowed with all good qualities," is merely a lovesick swain, lacking initiative, unfilial in his attitude to his parents, needing to be bribed to do his duty as a knight and defending his heritage absent-mindedly until faced with death; nor is he a very good Christian when he prefers hell with Nicolette and a gay company of sinners to heaven with ill-clad priests and the halt and the lame. These latter characteristics may explain the work's apparent lack of popularity in the middle ages, but it was sufficiently esteemed to be plagiarized in *Clarisse et Florent,* a continuation of the 13th-century *chanson de geste, Huon of Bordeaux.*

Floire et Blanchefleur, a romance of supposed Byzantine or Arab origin, known in two versions of the 12th and 13th centuries and in renderings in other European languages, including English, treats the same theme and is thought by some critics to have a common source with *Aucassin et Nicolette.* Here the roles and nationality (or religion) of the main characters are reversed. The 15-year-old Floire, son of a Saracen "king" of Spain, is in love with his childhood companion, Blanchefleur, daughter of a Christian slave of noble birth. Floire is sent away and his parents sell Blanchefleur to foreign slave dealers. Floire traces her to a tower where maidens destined for the emir of Babylon's harem are kept, induces the keeper to smuggle him inside in a basket of flowers and is discovered with Blanchefleur. Their judges, however, touched by their constancy, allow them to be married, and Floire takes his bride back to his kingdom, where he and all his subjects become Christians.

For both works consult R. Bossuat, *Manuel bibliographique de la littérature française au moyen âge* (1951) and *Supplément* (1955) under their titles. For *Aucassin et Nicolette* see editions by F. W. Bourdillon (1919) and Mario Roques (1925 and 1936). For *Floire et Blanchefleur* see editions by Margaret M. Pelan (1937) Bibliothèque Nationale, fonds fr. 375; Wilhelmina Wirtz (1937) Bibliothèque Nationale, fonds fr. 1447 and Felicitas Krüger (1938), both versions, all five manuscripts. There is an Eng. trans. by A. Lang (1887) and a modern French trans. by G. Michaut (1947). (F. J. WE.)

AUCH, a city of southwestern France, capital of the *département* of Gers, lies on and around a hill on the west bank of the Gers in the heart of Gascony, 45 mi. S. of Agen. Pop. (1962) 16,109. The town is divided into an upper and lower quarter joined by several flights of steps. Three bridges over the Gers link Auch with the suburb of Patte d'Oie. The old part of the town, which has some very narrow streets called *pousterles,* is centred on the Place Salinis from which the Escalier Monumental leads down to the river. On the north side is the cathedral of Sainte-Marie (1489 to 1662), one of the finest Gothic buildings of southern France. The chief features are the 113 Renaissance choir stalls of carved oak and the Renaissance stained-glass windows. The Greco-Roman façade dates from the 16th and 17th centuries, and the great organ (17th century) is one of the best in the world for the music of the time of Louis XIV. The 18th-century arch-

bishop's palace, with a 14th-century tower, adjoins the cathedral. Nearby are the museum of art and archaeology, the Gascon museum and the museum containing the archives of the *département* of Gers, a large library and collection of manuscripts. The prefecture, adjoining the cathedral, was once the palace of the archbishops of Auch. Tiles and tobacco are manufactured, while the chief trade is in Armagnac brandy, wine, cereals, poultry and *foie gras*.

Known in classical times as Elimberris, the city was the capital of the Celtiberian tribe of Ausci, and it became an important city of Roman Gaul. In the 4th century its bishopric was founded and after the destruction of Eauze it became the metropolis of Novempopulana. In 732 Saracen ravages forced the inhabitants to move their city from the right to the left bank of the Gers. The Benedictine abbey of St. Orens (of which little remains) was founded by Count Bernard of Armagnac in the 10th century, and the city was the capital of Armagnac in the middle ages. During the religious wars of the 16th century Auch remained in Catholic hands, except for a short occupation in 1569 by Huguenots under Gabriel, count of Montgomery. In the 18th century it was the capital of Gascony and the seat of a generality. Antoine Mégret d'Étigny, *intendant* from 1751 to 1767, did much to improve Auch and its commerce. The district was occupied for a short time in 1814 by British and Spanish troops. In World War II Auch was occupied by the Germans from Nov. 1942 to Aug. 1944.
(H. Po.)

AUCKLAND, GEORGE EDEN, Earl of (1784–1849), was governor general of India from 1835 to 1842. He was born at Beckenham, Kent, on Aug. 25, 1784, the son of William Eden, 1st Baron Auckland, to whose title he succeeded in 1814. In politics he was a consistent Whig and was president of the board of trade in Lord Grey's reform ministry (1830–34), and first lord of the admiralty under Lord Melbourne in 1834.

As governor general, Auckland was an excellent administrator; he extended irrigation, inaugurated effective famine relief, and adjusted the balance between oriental and European studies in India. He shared Lord William Bentinck's aim of expanding British trade and influence toward central Asia, and wanted a commercial treaty with the Afghan ruler, Dost Mohammed.

Forced to intervene in Afghanistan by Persian and Russian interference, Auckland chose to replace Dost Mohammed at Kabul by his rival, Shah Shuja (a move which would also prevent Afghan conflict with the British ally, Ranjit Singh). Auckland secured his communications with ruthless vigour—bullying, extorting money, and disregarding treaties as seemed expedient—and by 1839 Shuja was master of Kandahar and Kabul. For this victory, warmly welcomed in Britain, Auckland was created an earl (1839). But Shuja, lacking revenues, disciplined troops and personal popularity, depended on the British. They, with reforming or military zeal, interfered in Afghan administration. Their public reforms and private immoralities led to tribal revolts. Cuts in tribal allowances, which followed Auckland's orders to reduce the burden upon India's finances, transformed local risings into an attack upon the British forces in Afghanistan, and gross political and military blunders led to their destruction in 1841, during a winter retreat from Kabul. Auckland was recalled, when affairs were at their worst, in Feb. 1842.

He became first lord of the admiralty again in 1846, and died on Jan. 1, 1849.

See Janet Dunbar, *Golden Interlude: the Edens in India, 1836–1842*, with bibliography (1955). (J. B. Ha.)

AUCKLAND, WILLIAM EDEN, 1st Baron (1744–1814), English statesman, who, in 1786, negotiated with France the commercial treaty which usually bears his name, was born on April 3, 1744, the third son of Sir Robert Eden. He was educated at Eton and Christ Church, Oxford, and was called to the bar in 1769. Elected to the house of commons for Woodstock in 1772, he became undersecretary of state that same year, and successively commissioner of the board of trade (1776), commissioner of North America in connection with the dispute with the American colonies (1778), and chief secretary for Ireland (1780). He resigned this latter office in 1782, but he was for a short time joint vice-treasurer of Ireland in 1783. He strongly opposed the younger Pitt's proposals to establish free trade with Ireland in 1785, but agreed to go to France on a special mission relating to commerce (1785–87). Subsequently he was ambassador to Spain (1787–89) and to the Netherlands (1789–93). He was raised to the Irish peerage as Baron Auckland in 1789, and to the British peerage (with the same title) in 1793. In 1798 he joined Pitt's government as joint postmaster general. He attempted to dissuade Pitt from resignation in 1801 and himself retained office under Addington (afterward 1st Viscount Sidmouth) from 1801 to 1804. This terminated his friendship with Pitt and unlike some of his colleagues he was left out of Pitt's last ministry in 1804. In 1806 he was appointed president of the board of trade in Lord Grenville's ministry of All the Talents (the name given to the coalition government which came into office after the death of Pitt). He was never again in office after the dismissal of this ministry in 1807. He died at Beckenham, Kent, on May 28, 1814.

He had married in 1776 Eleanor Elliot, sister of the first Lord Minto. Of his large family, the most notable members were George, 2nd baron and earl of Auckland (*q.v.*), and Emily Eden (1797–1869), the novelist. The barony eventually passed to a younger son, Robert John (1799–1870), bishop of Bath and Wells who published his father's *Journal and Correspondence*, 4 vol. (1861–62), a useful source for the political history of the time.
(A. Al.)

AUCKLAND, the largest city and seaport of New Zealand, is situated on a narrow isthmus between the Waitemata harbour on the east and the Manukau harbour on the west coast of the North Island. Metropolitan Auckland consists of the city proper and more than 20 local authorities. Total pop. (1956) 381,063; (1959 est.) 413,100, 17.7% of the population of New Zealand. Total area about 95 sq.mi. Auckland has a temperate climate with a mean daily maximum temperature of 64.9° F., a mean daily minimum of 53.2° F. and an average annual rainfall of 48.9 in. The city is the administrative centre of the province of Auckland, which covers almost half the North Island and is rich in sheep, dairy pastures, forests and natural resources.

The land on both sides of the Waitemata harbour is undulating, broken intermittently with low hills, which are extinct volcanoes. Mt. Eden (643 ft.), once fortified by the Maoris (*q.v.*), and One Tree hill, the site of the grave of Sir John Logan Campbell, the "father of Auckland," are the best known.

The nucleus of the city, and the heart of the commercial and shopping area, is in and around Queen street, much of it on reclaimed land. Auckland has many fine public gardens, parks and reserves: Albert park (14 ac.), in the heart of the city, once the site of Albert barracks (the military post of the young colony during the Maori wars); Cornwall park (230 ac.), where Acacia cottage, Auckland's first wooden building (1842), is preserved; the zoological park (29 ac.); Ellerslie racecourse (30 ac.); and the Domain (194 ac.), containing winter gardens, sports fields, native bush and the Auckland War Memorial museum (1929, enlarged 1960). This museum has some of the finest Maori anthropological and ethnological exhibits in the world. The City Art gallery (1888), with its Frances Hodgkins collection, New Zealand paintings, 20th-century European sculpture and old masters, is the best in New Zealand. The public library (1887) is famous for its collection of manuscripts, incunabula and rarities given by Sir George Grey, its New Zealand and Maori collections and the comprehensive Reed Dumas collection. Each year the Auckland festival attracts artists from all parts of the world. Auckland university (1926), part of the University of New Zealand, includes the schools of architecture, engineering, fine arts and postgraduate obstetrics and gynecology. There are also two teachers' training colleges and more than 150 schools and colleges.

In 1957 nearly one-third of the overseas liners visiting New Zealand (from Great Britain, Canada, the United States, the far east, Australia) arrived in Auckland. The Waitemata, an arm of the Hauraki gulf, is a broad, deep, natural harbour, completely sheltered by an outlying chain of islands and dominated by the symmetrical volcanic island of Rangitoto (854 ft.). There are 27,301 ft. of good berthage, 14,789 ft. being available for overseas shipping. On the northern side of the Waitemata are Calliope

graving dock, which can take ships up to 595 ft. in length, and the chief New Zealand naval base and dockyard. Although the Manukau harbour, on which is situated the port of Onehunga, is larger and nearer to Australia, it is suitable only for small coastal vessels because of the bar at its entrance. One-third of New Zealand's total exports (dairy products, frozen meat, scrap iron, wool, hides, tallow, wood pulp) and nearly half of the total imports (petroleum, manures, iron and steel, wheat, sugar, motor vehicles, fresh fruit) passed through the seaport of Auckland in 1957. Whenuapai airport, 22 mi. N.W. of the city, provides services to Australia, Fiji, Great Britain, the United States and many other countries. Road, rail, air and sea transport link Auckland with the rest of New Zealand, while diesel and trolley buses ply between the city and the suburbs. A landmark on the skyline is the four-lane, 3,348-ft.-long toll bridge, opened in 1959, which spans the Waitemata harbour and links the rapidly growing north shore suburbs with the city.

Modern business establishments and large department stores provided employment for about one-third of the working population of Auckland in 1958. There was great industrial development during the 1950s and by 1959 Auckland, the major manufacturing centre of New Zealand, was employing 30% of all industrial workers and producing 29% of the total manufacturing output. The chief industries are engineering, motor assembly, timber and allied products, chemical products, freezing and fertilizing works, food manufacture, breweries, sugar refining, footwear, clothing and textiles, tanneries, plastics, and brick and cement works.

Founded in 1840, and the capital of New Zealand until 1865, Auckland has developed from a government store, a few traders' tents and a "sea of fern" to the largest and most vigorous city of the country.

See A. W. Reed, *Auckland, City of the Seas* (1955). (R. D.)

North Auckland Land District embraces the Auckland-Northland peninsula north of the southern fringe of the Franklin county and the lower reaches of the Waikato river. Dairy farming, fruit growing (at Henderson and Keri Keri) and market gardening (at Pukekohe) are the principal rural industries, but this district has a large urban population centred on the Auckland metropolitan area (448,218) and Whangarei (21,773). The concentration of industrial activity on the Tamaki isthmus is the greatest in New Zealand. The Bay of Islands was the centre of early European contacts before 1840 and Russell was the first capital of the infant colony. Kauri timber and kauri gum were for many years the economic mainstays of the district.

South Auckland Land District embraces regions popularly known as the Waikato, Coromandel, the Hauraki plains, the King Country, the Bay of Plenty and the Volcanic plateau. Hamilton (pop. [1961] 50,433) is the largest urban centre and the commercial and transport focus of one of the world's most intensive and productive dairying areas. Rotorua (25,074) and Tauranga, with Mt. Maunganui (24,759), a new and fast growing port, serve the Bay of Plenty and the new timber industries on the Volcanic plateau. Thames (5,314) was in the middle of the 19th century the centre of gold mining and heavy engineering industries and one of the five largest towns in the country. Huntly is the centre of an important coal mining district. (K. B. C.)

AUCKLAND ISLANDS, a group of uninhabited islands in the southern Pacific ocean about 200 mi. S. of New Zealand in 50° 32′ S., 166° 13′ E. They cover about 234 sq.mi. and were discovered in 1806 by Captain Bristow. The islands are of volcanic origin. They were granted to a private company by the British government as a whaling station, but the establishment was abandoned in 1852. The islands belong politically to New Zealand, which maintains there a depot of food and clothing for shipwrecked sailors.

AUCTION. The auction has long been an effective marketing institution for the purchase and sale of real and personal property at a reasonably fair price. An auction usually involves open public bidding, preceded by an inspection by prospective purchasers of the items to be auctioned. The inspection period enables buyers to evaluate various lots, determine comparative grades or qualities, and arrive at a reasonable price to offer at auction time. Normally, the auctioneer is the agent of the seller. Auction sales are subject to a great variety of regulations stemming from custom, common law and statutes.

The traditional auction process involves a succession of increasing bids or offers by potential purchasers. Competitive bidding ceases when the highest bid is accepted by the auctioneer and the property to be sold is, by the fall of the auctioneer's hammer, "knocked down" to the successful bidder. Unless the auction is advertised to be "without reserve" the auctioneer may withdraw goods without accepting the highest bid or offer. On the other hand, a bid may be withdrawn at any time before it is accepted by the auctioneer. A Dutch auction is conducted somewhat differently. The seller, through the auctioneer, offers property at successively lower prices until one of his offers is accepted or until the price drops so low as to force the withdrawal of the offered property.

Types of Auctions.—The F.O.B. auction is usually a telegraphic auction where bids are received by wire on carloads of fruits and vegetables. Such bids are received by the auctioneers simultaneously over leased wires from individual or assembled buyers in various parts of the country. There have been fruit auctions in the United States since the middle of the 19th century, and their continued existence helps maintain the flow of fresh fruits and vegetables into major metropolitan areas.

In the United States the loose leaf tobacco auction has been a fairly constant method of purchase and sale of tobacco. At such an auction each grower's lot, usually piled separately from the lots of other growers, is placed in flat baskets. This method of display permits the buyer to identify and to evaluate each lot. Loose leaf tobacco auctions have been especially helpful to the small growers of tobacco, who may sometimes be in a weak bargaining position, because they tend to equalize prices between markets and between similar lots of loose leaf tobacco shipped into the same auction market.

Items other than tobacco that are frequently sold at auction include secondhand household goods, used farm equipment, collections of art objects (*see* Art Selling) or curiosities, antiques, stamps, rare books and unclaimed baggage. In a sense, the great exchanges where commodity futures and securities are bought and sold resemble auctions. On the New York stock exchange, for example, floor traders make bids to buy securities and offer securities for sale. Whenever a bid and an offer coincide, a transaction takes place.

History.—In Europe in earlier centuries trade auctions were regularly held to dispose of products, especially those imported from the colonies. This was particularly true of imports such as wine and leather. The history of European auctions clearly indicates the extent of such transactions, especially in London, Amsterdam and Hamburg. It was not until the Industrial Revolution that processed raw materials, such as cotton goods, found their way into the various auction markets of Europe. Such products became major trade items between countries and played a very important role in the development of the mercantile system.

Auctions provided an exceptionally rapid and effective means of disposing of goods, especially perishable products. In the European markets it is recorded that fruit was shipped from countries such as Italy, Cuba, Spain, the Netherlands and the West Indies into the wholesale auction markets in major cities. This practice was ultimately adopted in the American colonies following the establishment of cities such as Boston, New York and Philadelphia.

The earliest record of an auction in the American colonies is an application filed to hold a sale in New Amsterdam in 1662. Details of other 17th-century auctions are meagre but become fuller after 1700. Most information comes from newspaper announcements of sales, printed broadsides and catalogues of sales. Two comprehensive lists of all known American auction catalogues were published by the New York Public library, George Leslie McKay's *American Book Auction Catalogues, 1713–1934* and Harold Lancour's *American Art Auction Catalogues, 1785–1942*. Together they account for nearly 20,000 sales. But a great many sales such as the "country auctions" of today did not have printed catalogues.

The earliest auction catalogue extant was for a sale of the books of Ebenezer Pemberton at the Brown coffee house in Boston on July 2, 1717. For most of that century Boston remained the important auction centre. Auctioneers themselves were specialists who would conduct a sale for a set fee or for a stated percentage of the receipts. Gradually individual auctioneers in Boston, Philadelphia and New York gained sufficient prestige and business success to establish firms with their own auction rooms.

Over the years it became clear that for a product to be successfully auctioned it should possess certain characteristics:

1. A reasonably constant supply of the given product (such as fruits and vegetables) in season.
2. Relatively easy grading according to established standards of quality.
3. Uniform packaging or uniform size lots. (Whether they be small lots or carload quantities makes little difference.)
4. Consistent with the above, auction products would normally have to arrive at the auction point in a sufficiently large quantity to permit easy handling at relatively low cost.

Auction points, both in the United States and abroad, were normally located near transit terminals. Following the development of the railroad in the 19th century and of the long-haul truck in the 20th century, the auctioneer would obtain car manifests, or otherwise prepare lists, and would advertise them for the information and guidance of the buying public. This enabled the auctioneer, assuming a relatively constant flow of goods, to schedule regular auctions, provide for inspection and conduct his auction at stated times and places.

Aside from commodities and real estate, the auction also served as a means for transferring ownership of slaves. There are evidences of slave auctions in Greek history on a fully established basis during the Homeric period. The practice persisted through the early period of Christianity into the period of the modern slave trade, which developed about the time of the decline of serfdom. The Spaniards engaged in the slave trade, selling slaves in the markets at Seville through transactions similar to that of the auction. English slave traders brought slaves into the American colonies where they were frequently sold at auction to the tobacco planters. American colonial ship owners also engaged in the slave trade.

Auction procedures and customs have varied over the years. It was once common practice to bid until a candle burned an inch or went out, until a sandglass ran out, or until a running boy reached his goal. The last bidder became the successful purchaser. More recently the fall of the auctioneer's hammer, when the auctioneer believes he has reached the peak bid, has become the customary way of signifying a sale. Following a sale, but usually for only a limited time, the auctioneer binds the purchaser by signing on his behalf the memorandum of agreement.

Auctions have usually been conducted by individuals who are licensed auctioneers or by auctioneering companies and their agents. Property to be auctioned is often described in writing. Chattels may be described in a catalogue, or through posting a list, such as a car manifest, and real estate may be described in a document known as the particulars of sale. Such descriptions state the terms of sale and set forth the relative rights and liabilities of the parties to the sale.

Laws and Regulations.—Originally, auctions were regulated by custom, but as the common and statutory laws of sales and contracts developed, auction transactions were made subject to them. In Europe, especially in England, legislation developed to control fraud and abuse. The English Auctioneers act of 1845 required the annual licensing of auctioneers and required them to exhibit at the auction, a board showing the name and address of the auctioneer. The Sale of Land by Auction act of 1867 contained certain provisions about reserve prices and biddings in the sale of land (including buildings). Similar provisions about auction sales of chattels and livestock were contained in the Sale of Goods act of 1893. The Auctions (Bidding Agreements) act of 1927 rendered it a criminal offense for dealers in goods to take part in what is popularly known as a "ring" or an agreement for a "knock-out." The latter is an agreement between dealers not to bid against each other, in order that one of them may obtain the articles at a low price; the resulting profit is then divided among those taking part. A copy of the 1927 act must be exhibited at auction sales.

Professional Organization.—Systematic arrangements are made in England for the training and professional welfare of auctioneers and estate agents. The beginnings of professional organization can be traced to the end of the 18th century when the Select Society of Auctioneers, which still exists as a dining club, was formed at the Piazza coffee house on May 20, 1799. At mid-20th century the senior professional institution representing auctioneers and estate agents was the Chartered Auctioneers' and Estate Agents' institute. Another body representing auctioneers was the Incorporated Society of Auctioneers and Landed Property Agents.

AUCTION BRIDGE: *see* BRIDGE.

AUCUBA, a small genus of the dogwood family (Cornaceae) containing the familiar Japanese laurel (*Aucuba japonica*), grown in frost-free places or in cool greenhouses. It bears male and female flowers on distinct plants; the red berries often last until the next season's flowers appear. A variegated form is the gold-dust tree.

AUDE, a *département* of southern France, formed in 1790 from part of the ancient province of Languedoc (*q.v.*), is separated from Spain by Rousillon (*département* of Pyrénées-Orientales) and lies southwest of Hérault in the plain of Languedoc. Area 2,406 sq.mi. Pop. (1962) 269,782. From the coast of the Gulf of Lions it extends inland into the Gate of Carcassonne, between the Montagne Noire portion of the Massif Central and the outer ranges of the eastern Pyrenees, including the Corbières massif. Both these flanking highlands rise to about 4,000 ft. Most of the *département* lies within the drainage basin of the Aude river, but it extends westward beyond the watershed (col de Naurouze) into the basin of the Garonne river. Since 1685 the Canal du Midi has connected the Mediterranean with the Atlantic through this gap. The railway from Toulouse to Narbonne bifurcates northward to Béziers and the Rhône valley and southward to Perpignan and Spain. The regular, sand-dune coast is backed by extensive lagoons, notably those of Sijean and Leucate. La Nouvelle is an artificial port, formed by cutting a passage through the sandspit for the Canal de la Robine, a branch of the Canal du Midi, which serves Narbonne. (*See* MIDI, CANAL DU.)

The lowlands of Aude have a typical Mediterranean climate, with notably mild winters and hot, sunny, dry summers, and the olive is grown as far west as Castelnaudary. The lowlands are very largely devoted to growing vines, which are now virtually the only crop, producing vast quantities of cheap wine. Minervois, the limestone foreland of the Montagne Noire, is part of the vineyard country. Mineral resources are comparatively unimportant, the chief being the sulfur of Le Malvezy, near Narbonne, and the iron ore of Leucate on the coast. Quillan, a Pyrenean foothill town in the Aude valley in the southwest, has become an important centre for the manufacture of plastics. Carcassonne (the capital), Narbonne (*qq.v.*) and Limoux give their names to the three constituent *arrondissements*. They are rich in historical and architectural interest, especially Carcassonne, where the Cité, encased in its ancient fortifications on a defensive hill site, overlooks the later, planned town of the 13th century across the Aude river. The *département* forms the diocese of Carcassonne, and comes under the court of appeal and the *académie* of Montpellier. (AR. E. S.)

AUDEN, WYSTAN HUGH (1907–), English-born poet, one of the most consistently interesting and variously gifted poets of the mid-20th century, was born on Feb. 21, 1907, at York. He was educated at Gresham's school, Holt, and Christ Church, Oxford. For a time a schoolmaster, he soon began to earn his

living as a writer. In 1935 he married Erika Mann. Throughout the 1930s he was deeply involved in social and political considerations; his central concern has always been man in society. For him, and for those others who are sometimes called "the Auden group," T. S. Eliot's philosophical attitudes were often unattractive; but his—and Gerard Manley Hopkins'—poetic examples were respected. In this decade—see especially *Look Stranger* (1936) and *Another Time* (1940)—Auden's best verse mirrors with epigrammatic pungency the current social and psychological unease. Only one of the three plays he wrote in collaboration with Christopher Isherwood, *The Ascent of F. 6* (1936), is worth much attention; but then, as later, he wrote some excellent lyrics. In 1937 he received the king's medal for poetry.

The religious foundation of all Auden's thinking was plain by 1940, by which time he had settled in the United States (he subsequently adopted U.S. citizenship). Four long and uneven poems first showed this basis directly, the last, *The Age of Anxiety* (1947), being the most ambitious. In 1956 Auden was made professor of poetry at Oxford though his home remained the United States. His most striking later development was in symbolic landscape poetry, sometimes with a syllabically counted line (*see* "In Praise of Limestone" in *Nones*, 1951).

BIBLIOGRAPHY.—F. Scarfe, *Auden* (1949); R. Hoggart, *Auden* (1951) and *W. H. Auden* (1957); J. W. Beach, *The Making of the Auden Canon* (1957). (RI. H.)

AUDE RIVER, of southwest France, is 138 mi. long, with a basin of 2,062 sq.mi., rises in the eastern Pyrenees near the Pic de Carlitte and flows into the Gulf of Lions. The upper course is through deep gorges (except near Axat) and is harnessed for hydroelectric power. Below Carcassonne its course, from north, turns due east, skirting the Corbières, to enter the Mediterranean about 12 mi. E.N.E. of Narbonne. The Aude gap, between the Pyrenees and the Montagne Noire, was one of the great historic thoroughfares of western Europe.

AUDIENCE, usually an assembly of hearers (Lat. *audire*, "to hear") or spectators, often designates the formal interview which a spiritual or temporal ruler grants to an inferior and, more particularly, the ceremonial presentation of credentials by ambassadors or others to a sovereign.

The pope holds audiences with all grades of ecclesiastical and lay dignitaries, besides giving private, semiprivate and public audiences to ordinary persons.

In Great Britain, audience is the right of access to the sovereign of peers individually and of the house of commons collectively. The audience court, now merged in the court of arches, was an ecclesiastical court of the archbishops of Canterbury and York.

In France, *audience* is the sitting of a law court for hearing actions. In Spain, the *audiencia territorial* is a regional high court and the *audiencia provincial* is a court of first instance for criminal offenses. The Spanish American court called *audiencia pretorial* allowed appeals only to the council of the Indies in Spain.

AUDIFFRET-PASQUIER, EDME ARMAND GASTON, DUC D' (1823–1905), French statesman, prominent in the early years of the third republic, was the nephew and adoptive son of the baron Étienne Denis Pasquier (created Duc Pasquier in 1844). Born in Paris on Oct. 23, 1823, he served as commissioner (*auditeur*) at the *conseil d'état* from 1845 to the revolution of 1848. Under the second republic, as an Orleanist, he lived in retirement. During the second empire he was elected a member of the *conseil général* of the Orne *département*, but failed at the general elections of 1863 and 1869. Elected to the national assembly as member for Orne in Feb. 1871, he attracted attention as a forceful critic both of the fallen imperial regime and of the Government of National Defense. He became chairman of the right centre group in 1873 and was elected vice-president of the national assembly in 1874. After the fall of Thiers in May 1873, Audiffret-Pasquier conducted the negotiations between the two royalist groups, the Legitimists and the Orleanists, with a view to reestablishing the monarchy in France and so was partly responsible for the failure of the project when the comte de Chambord (*q.v.*) tried to insist on the white flag of the old regime instead of the tricolour. Yet he retained the confidence of the assembly and was its president when, in 1875, the new constitution was adopted. From 1876 to 1879 he was president of the senate. In 1878 he was elected to the French Academy. He died in Paris on June 4, 1905. (JE. V.)

AUDIO FREQUENCY, a frequency in the band corresponding to normally audible sound waves. The upper limit ordinarily lies between 10,000 and 20,000 cycles. The lower limit is about 16 cycles. *See* also HEARING: *Phenomena of Hearing*.

AUDIO-VISUAL EDUCATION commonly denotes methods used in formal teaching, but the principles are applied also in business and industry, the armed services and to some extent in the field of mass communications.

Materials commonly considered audio-visual include objects and models; diagrams, charts, graphs, cartoons and posters; maps and globes; pictures, slides and other projected transparencies; filmstrips (slide and slide-sound films), recordings, transcriptions and tapes; motion pictures (silent and sound); radio and television. Facilities include the blackboard; bulletin (tack) board; display cases, tables and areas; museums; flannel boards and electric boards. Audio-visual equipment includes picture projectors of many kinds, record players, tape recorders, equipment and facilities for recording and broadcasting, and the various types of equipment used by teachers and pupils in the preparation of instructional materials, such as photographic equipment, dry mounting presses and stenciling and lettering devices. Such activities as field trips and the use of resource people are usually considered part of audio-visual programs, and even demonstrations, dramatizations, experiments and creative activities are sometimes included.

The purpose of audio-visual education is to improve learning. Educators have come to recognize that traditional methods of teaching by lecture and textbook frequently result in students memorizing meaningless facts without actually learning. It has been determined that the most effective learning takes place when the individual has direct experience with the subject under study, "learning" being defined as "changed behaviour." In other words, a student learns best by doing. Not all subject matter, however can be taught through direct experience. Hence, there is need for instructional methods and materials that provide an effective substitute for direct experience.

A number of investigators have found that the use of audio-visual materials, together with textbooks and other devices, makes an improvement in students' performance that is statistically measurable by testing procedures. Educational theorists point out that perception is largely visual experience, reinforced by the auditory and other senses. This phenomenon suggests that experiences rich in visual stimuli should evoke the strongest responses in a classroom or other learning situation, as well as in other kinds of human activity. Thus, the audio-visual mediums can contribute to the creation of more meaningful learning experiences. In particular, in the study of any real life phenomenon or situation where vision is important, the motion picture comes closest to simulating actual experience.

Audio-visual education as a systematic method of teaching is a development of the 20th century, but throughout history man has shown a natural inclination to learn and to teach with pictures, specimens, demonstrations and the like. Johann Amos Comenius (*q.v.*), a Czech educator, was one of the first to record a stated philosophy of audio-visual education. His *Orbis sensualium pictus*, published in 1658, was profusely illustrated with drawings, each playing an important role in teaching the lesson at hand. Comenius was followed by other great educators, including Rousseau, John Locke and J. H. Pestalozzi, who advocated the use of sensory materials to supplement words in teaching.

The problem of perception by visual, auditory or other sensory experiences has been a subject of investigation since the beginnings of experimental psychology. Research in the use of audio-visual materials had its beginnings before 1920 and developed rapidly after 1929. Among the earliest experimental studies of the influence of motion pictures upon learning were those of D. R. Sumstine (1918) and J. V. Lacy (1919). J. J. Weber (1922) investigated the comparative effectiveness of several visual aids.

and V. C. Arnspiger (1933) was one of the first to measure the effectiveness of sound motion pictures. By and large, however, the research of unsubsidized individuals proved less effective than that of co-ordinated and subsidized teams of specialists, such as those that carried on the Eastman studies (B. D. Wood and F. N. Freeman, 1929), Yale University studies (D. C. Knowlton and J. W. Tilton, 1929), Harvard studies (P. J. Rulon, 1933), the Payne fund studies (W. W. Charters, 1933) and the American Council on Education studies (1936–42).

During and after World War II the wide use of audio-visual materials by the armed services provided opportunity for extensive investigation of audio-visual materials, methods and administrative practices. The study reported by C. I. Hovland *et al.* in *Experiments on Mass Communication* (1949), in which the effects of the *Why We Fight* films were investigated, clarified some areas in which the previous evidence was conflicting, and provided data on the problem of changes in opinion. A study reported by J. J. Gibson, *Motion Picture Testing and Research* (1947), proved of general value to film users and producers, and a series of research studies reported by C. F. Hoban, Jr., emphasized the need for trained personnel and an organized program to promote the use of audio-visual materials. By the second half of the 20th century, close to 200 research studies had explored the teaching effectiveness of audio-visual materials. Much of this study was made possible by the continuing interest and support of the armed services. It was further stimulated, however, by the growth of interest in teaching by television, which received support from the Ford foundation and other organizations.

Edgar Dale and Hoban stated that research supported the following claims for the effectiveness of audio-visual materials properly used in teaching (W. S. Monroe [ed.], *Encyclopedia of Educational Research*, p. 1323, Macmillan, New York, 1941).

(1) They supply a concrete basis for conceptual thinking and hence reduce verbalistic response of students; (2) they have a high degree of interest for students; (3) they supply the necessary basis for developmental learning and hence make learning more permanent; (4) they offer a reality of experience which stimulates self-activity on the part of pupils; (5) they develop a continuity of thought; this is especially true of motion pictures; (6) they contribute to growth of meaning and hence to vocabulary development; (7) they provide experiences not easily secured in other materials, and hence they contribute to the depth and variety of learning.

Evidence indicates significant gains in informational learning, retention, recall, thinking, reasoning, interest and imagination, and better assimilation and personal growth when audio-visual materials are properly used. Best results are achieved when a variety of audio-visual materials, printed materials and follow-up experiences are used together. Experiments have shown that good films can teach a body of subject matter efficiently, but that films cannot replace the teacher. Thus, where thoroughly qualified teachers are unavailable, specially designed films, properly administered, can do an effective job of teaching. It is recognized, however, that the best teaching is accomplished by highly qualified teachers using educational films and other modern audio-visual tools of instruction.

Audio-visual materials have proved effective in all areas of learning, in all subject-matter fields and at all ages. Where effectiveness is tested in terms of verbal responses to information tests, films seem to be relatively more effective for mediocre pupils; but where effectiveness is tested in terms of ability to make verbal generalizations, films are more effective for bright pupils.

United States.—Pictures, book illustrations, maps, globes, charts, specimens and models were recognized adjuncts to teaching long before the term audio-visual was conceived. However, it was not until the turn of the 20th century that organized programs of visual instruction began to emerge. An early development was the co-operative arrangement between city school systems and local museums. In 1905 the first school museum was started in St. Louis, Mo., followed during the next few years by school museums in Cleveland, O., Chicago, Ill., and Reading, Pa. By 1923 many larger school systems had departments of visual instruction.

The visual material provided in early school museums consisted of drawings, paintings, photographs, stereographs, lantern slides, models and displays of various kinds. School libraries of visual materials still provide most of these types of visual aids. Although the early $3\frac{1}{4} \times 4\frac{1}{4}$ in. slide gave way in later years to the smaller, more convenient 2×2 in. slide, transparencies are still used in cases where teachers, and even students, desire to produce their own hand-made slide materials, especially for use with the overhead projector.

By far the most widely used of still picture materials is the filmstrip (a series of still pictures on 35-mm. film, usually with captions, projected one at a time), introduced during the early 1920s. Teachers have found the filmstrip an effective teaching tool—inexpensive and easy to use.

The phonograph record was early recognized as an important teaching device, particularly in music education. In later years the recording of drama, poetry and stories became common. Disk and tape recorders are also used, primarily by teachers of music, speech and foreign languages.

The potentialities of education by radio were recognized within a year after the first commercial radio broadcast in 1920, but effective educational radio did not begin until a decade later. A number of universities licensed their own stations; local stations and networks developed educational programs; and radio receivers appeared in classrooms. Increasing numbers of school systems operated low-power FM radio stations that broadcast programs directly to classrooms; and educational television stations developed programs for classroom audiences.

Probably the motion picture is the most dynamic of all the audio-visual mediums. While the potential value of films for use in education was early recognized, schools were slow to make wide use of them. Much impetus for organized visual education in the early 1920s resulted from World War I experience with motion pictures. J. R. Bray's techniques in using animation, which he applied to teaching films, were successfully used in the armed services and in classrooms. Progress in the use of films was retarded in part by technical problems, but the audio-visual idea received added stimulus in 1923 with the introduction of the relatively lightweight and portable 16-mm. projector and 16-mm. safety film. Pioneer efforts in the production of classroom films were the Yale Chronicles of America photoplays and the Eastman silent films. In 1929 the Western Electric company organized a company to produce sound classroom films for the few 35-mm. sound projectors then used in U.S. schools. This company, Erpi Classroom Films, Inc., developed a program of classroom film production and later produced films independently as Encyclopædia Britannica Films Inc. In the early 1930s the 16-mm. sound projector and film were introduced and became the standard for the educational field.

By the mid-1930s the findings of research and the waning of the great depression stimulated a decided growth of the audio-visual field. By 1940 an estimated 10,000 schools had acquired 16-mm. sound motion-picture projectors; hundreds of school systems and universities had established libraries of audio-visual materials. *Educational Screen* (established in 1922) weathered the depression, and other publications were launched. Audio-visual conferences and workshops rapidly became a potent force in the movement.

Entrance of the United States into World War II demanded the immediate training of a very large number of men and women who had to learn new skills, to gain new knowledge and to be imbued with new attitudes. Every resource of mass communication was assembled. The army and navy each established extensive facilities for the production and utilization of motion pictures, filmstrips and other audio-visual materials, and brought together specialists in education with specialists in motion-picture production and other communications methods.

The navy alone made or supervised the making of 3,300 motion pictures and filmstrips in a period of $3\frac{1}{2}$ years during the war, and more than 10,000 different film titles were used in its training program. Twenty-five hundred motion pictures were made for the army film program.

Most of the materials produced and distributed by the armed services were designed to teach mechanical skills, ranging from

how to assemble a rifle to how to navigate a ship, but extensive experiments also were made with the use of films and other materials to shape attitudes.

After World War II there was a steady increase in the use of audio-visual materials in the schools of the United States, as well as in industrial training programs. The success of the armed services with audio-visual methods of teaching provided an important incentive. However, the chief stimulus in the second half of the 20th century was the fundamental change in educational philosophy and teaching methods. Increasing numbers of teachers embraced the philosophy that learning is improved if the written and spoken word is supplemented by related experiences. The education departments of most universities and colleges offered courses in the use of audio-visual materials, some of them at the graduate level. A number of the state universities and teacher training institutions assembled libraries of motion pictures and other materials to serve schools on a state-wide and regional basis. Some went into the production of films and other materials, including kinescopes for educational television.

In the second half of the 20th century, most schools and school systems of any size owned motion-picture or filmstrip projectors, tape machines, record players and other equipment, though few were adequately equipped according to generally recognized standards. A survey of audio-visual education in urban school systems made by the U.S. department of education reported a ratio of approximately 24 motion-picture projectors for each 10,000 students. The number of film libraries providing materials to schools was approaching 4,000 and was increasing steadily. There were about 20,000 available motion pictures and filmstrips on subjects taught in the school curriculum, and new materials were being added at the rate of several hundred new titles each year.

In most schools the audio-visual program is directed by a member of the teaching staff especially trained in the use of these materials or by the librarian. In larger city and county school systems the program is supervised by an audio-visual director from a centre equipped and staffed to serve the entire system. School budgets include appropriations for the audio-visual program, and most state departments of education have appointed audio-visual staff specialists. By the 1950s a number of states had adopted a policy of allocating funds specifically to the audio-visual program, and in the National Defense act that became law in 1958, the federal government appropriated funds for research and experimentation in more effective utilization of television, radio, motion pictures and other mediums for educational purposes. Activities in this field of education were co-ordinated nationally through the Department of Audio-Visual Instruction of the National Education association, the National Audio-Visual association, the National Association of Educational Radio and Television Broadcasters and the National Association of Educational Broadcasters.

Great Britain and the Commonwealth.—Audio-visual programs were well established in many British schools by the second half of the 20th century, and most colleges that trained teachers offered courses in this field. As early as 1923 the Imperial Education conference had established a committee to investigate the evidence that the film could be a valuable teaching aid. Its report led to establishment of a film commission in 1929 whose findings in turn led to the creation of the British Film institute (with its Scottish counterpart, the Scottish Film council). Survey and guidance assistance by these organizations was a major factor in the growth of the use of films in British schools.

During World War II the British government's information films for civilian and military use generated new interest in films and other audio-visual materials. After the war the field developed rapidly. After 1946 national guidance was provided by the National Committee for Visual Aids in Education, which co-ordinated the needs of teachers with available production facilities. After 1948 a second national organization, the Educational Foundation for Visual Aids, arranged for production of films requested by the national committee, distributed them, sold and rented non-sponsored educational films and filmstrips and all makes of projectors.

Many British educators tended to classify films as either background or lesson films. Background films are directed toward extending the student's experience beyond the confines of the classroom. Documentary films (especially on contemporary life) are considered suited for use as background films, and the documentary film movement in Great Britain had an important influence on the use of films in education. Lesson films are designed to correlate directly with the curriculum. For many years British educators were inclined to favour silent films and filmstrips on the ground that these allow the teacher to provide his own commentary based on specific lesson objectives and the understanding of his students. In later years the increasing availability of sound films led to their greater use. A notable development was experimentation with the "visual unit," a package of audio-visual materials dealing with a particular subject. This might include charts, records, still pictures, films and other materials combined to provide the teacher with a complete teaching program. A widely used program of radio broadcasting to classrooms was developed by the British Broadcasting corporation.

In Canada the use of films received special stimulus through the work of the National Film board of the federal government, but the audio-visual program was independent of that agency. Each Canadian province appointed an audio-visual director who worked through the provincial department of education; each province operated a film library for use in its school system and made use of other aids, such as pictures, wall charts, dioramas, stereographs and radio and television broadcasts. Many school districts set up and maintained visual aids libraries supplementary to those supplied by the departments of education.

The history of audio-visual education in Australia and New Zealand is somewhat similar to that of Canada. After 1945 the Australian National Film board followed the Canadian pattern. Most of the dominions and colonies of the British Commonwealth had established visual aid departments and educational film libraries by the 1950s, and the production, distribution and use of classroom films, filmstrips and other audio-visual aids became an integrated and accepted part of the educational system.

Other Countries.—The centrally regulated educational systems in continental Europe are not conducive to the growth of the use of audio-visual teaching materials. While efficient in broad curriculum planning, national ministries of education are at a disadvantage when dealing with needs and opportunities in individual schools. Maps, bulletins, charts and blackboards have been traditionally used by European teachers in all grades, but filmstrips and films have been slow to follow because of lack of funds, conservative teaching policies and lack of electrification. Some small countries, such as Denmark and Hungary, used silent films in the first quarter of the 20th century, and Germany and France sponsored ambitious experiments with films in science and geography. Switzerland, capable of utilizing films from the large countries surrounding it, organized a program, but it took root slowly because of conservative teaching practices. Sweden and Norway became the two European countries with the largest number of sound films in proportion to their student populations. Denmark used silent films predominantly through the 1950s. After World War II France began rebuilding its program of sound films, especially for the lower grades; Italy also set up an audio-visual educational program, and film libraries were established in Belgium and the Netherlands. In all these countries the use of silent filmstrips was expanded faster than the use of motion pictures, with France, Germany and the Scandinavian countries leading with the largest numbers of filmstrips in their school catalogues. Among other countries, India established an exceptional program. Audio-visual materials of many types were used extensively in the Fundamental Education program with the help of teams from the United Nations Educational, Scientific and Cultural organization. The program, as developed by UNESCO, was planned to make available in educationally underdeveloped areas of the world functional knowledge for the improvement of agricultural production, health and sanitation, community organization and local industries and crafts, and for the reduction of illiteracy. As an outcome of two UNESCO conferences on international film exchanges, held in

Tangier and Paris, the International Centre of Films for Children was established with headquarters in Brussels, Belg.

AUDIT, an investigation of an activity by someone not connected with it to determine whether it is being carried on in conformance with its objectives. Professional auditing involves the examination of the activities, records and reports of the enterprise by accounting specialists who are not the same accountants responsible for their preparation. An auditor is one who plans or participates in such investigations.

Perhaps the most familiar type of auditing is the administrative or pre-audit, which consists of investigating individual vouchers, invoices or other documents for accuracy and proper authorization before they are paid or entered in the books. Internal auditing is a relatively new type of auditing and is designed primarily to meet the needs of management. Internal auditors try to determine whether the requirements of the accounting system are being met effectively and also whether the system itself is adequate for management needs. Thus internal auditing, according to the Institute of Internal Auditors, is a means of managerial control that operates by appraising the effectiveness of other controls.

Public auditing by independent accountants has acquired professional status and has become increasingly popular with the rise of large business units and the separation of ownership from control. The public accountant performs sufficient tests and examinations to determine whether the management's statements fairly present the firm's financial position and operating results. Unbiased, independent evaluations of management reports are of interest to actual and prospective shareholders, bankers, suppliers, employees, lessors and governmental agencies. In all English-speaking countries public auditors are usually certified, and high standards are encouraged by professional societies. (*See* CERTIFIED PUBLIC ACCOUNTANT.) The American Institute of Certified Public Accountants, the Institute of Chartered Accountants in England and Wales, and similar groups in Australia, New Zealand and Canada have developed standards for independence and competence, for appraising internal controls, for establishing evidence to support opinions, and for reporting.

In the United States the auditing of federal accounts is administered by the comptroller general, who is the head of the general accounting office, an agency independent of the executive branch of the government and responsible directly to congress. This agency was created in 1921 to be responsible for auditing receipts, expenditures and use of public funds. Most states conduct the audit function through comptrollers' offices, but many municipal and many county units make use of independent accounting firms. In the British Isles the Exchequer and Audit act of 1866 empowers the sovereign to appoint a comptroller and auditor general to examine the accounts prepared by the departments of public service. In practically all European countries there is a department charged with auditing the public accounts, such as the *cour des comptes* in France, and the *Rechnungshof des deutschen Reiches* in Germany. Local boards, large cities, corporations and similar bodies ordinarily have official auditors for the purpose of examining and checking their accounts and looking after their expenditures.

The word auditor is now almost synonymous with professional accountant. In Scotland the title auditor sometimes corresponds with the English taxing master. In France the term refers to legal officers attached to the *conseil d'état.* In many European countries lawyers skilled in military law are called auditors. *See also* ACCOUNTING.

AUDLEY OF WALDEN, THOMAS AUDLEY, BARON (1488–1544), English lawyer, who was lord chancellor from 1533 to 1544, owed his advancement to the subservience he showed to Henry VIII during the breach with the papacy. Born at Earls Colne, Essex, he studied at Cambridge and the Inner Temple, became town clerk of Colchester, and by 1521 was a justice of the peace for Essex. In 1523 and 1529 he represented that county in parliament. He was chosen speaker of the house of commons in Nov. 1529, and his services in that office led to his appointment first as lord keeper of the great seal (May 1532) and then as lord chancellor (Jan. 1533). As chancellor he presided at the trials of Bishop Fisher and Sir Thomas More in 1535 and of the Lincolnshire rebels in 1536. He also presided, as lord steward, at the trial of the marquess of Exeter (1538) and took a leading part in the attainders of Thomas Cromwell (1540) and Catherine Howard (1542). He was created Baron Audley of Walden on Nov. 29, 1538, and was made a knight of the Garter in 1540. He received a considerable share of monastic property and is remembered as the founder of Magdalene college, Cambridge (1542). He resigned the lord chancellorship, because of ill-health, on April 21, 1544, and died on April 30. (R. B. WM.)

AUDRAN, the name of a family of French artists and engravers. The first who devoted himself to the art of engraving was Claude Audran, born 1597, and the last was Benoît, Claude's great-grandson, who died in 1772. The two most distinguished members of the family are Gérard and Jean.

GÉRARD OR GIRARD AUDRAN (1640–1703), engraver, was the third son of Claude Audran and was born at Lyons on Aug. 2, 1640. He was taught the first principles of design and engraving by his father, and continued his studies in Paris. There, in 1666, he engraved for Charles le Brun "Constantine's Battle With Maxentius," his "Triumph" and the "Stoning of Stephen," which placed Audran in the first rank of engravers at Paris. He spent the years 1667–70 in Rome, where he engraved several fine plates. J. B. Colbert was so struck with the beauty of Audran's works that he persuaded Louis XIV to recall him to Paris. On his return he was appointed engraver to the king, from whom he received great encouragement. He died at Paris on July 26, 1703. His engravings of Le Brun's "Battles of Alexander" are regarded as the best of his numerous works.

JEAN AUDRAN (1667–1756), nephew of Gérard, was born at Lyons. He was 80 years of age before he gave up his work, and nearly 90 when he died. The best prints of this artist are those in which the etching constitutes a great part, and he finished them in a bold, rough style. The "Rape of the Sabines," after Poussin, is considered his masterpiece.

AUDUBON, JOHN JAMES (1785–1851), U.S. artist-naturalist, made known to the world, better than ever before, all the then-known birds of America through the dramatic beauty of his drawings and the vividness of his prose. Born at Les Cayes, Santo Domingo (now Haiti), April 26, 1785, the son of Lieut. Jean Audubon, French naval officer and planter, he spent his boyhood in France in comparative luxury under the care of an adoring foster mother. He early showed an interest in drawing birds, but cared little for school. When 18 years old he was sent to the United States to enter business. His interest in birds and in drawing them increased, but his business ventures were unsuccessful.

In 1808 Audubon married Lucy Bakewell. In 1820 Audubon concentrated his efforts on what was to become his great work, the illustrating of all North American birds. Supported by giving drawing lessons and painting portraits, and by his wife's teaching, he collected and painted birds in the eastern and southern United States.

By 1826 he had enough material to consider publication and took his drawings to Europe, in search of patrons and publishers. In Great Britain his genius was immediately recognized by scien-

tific and art circles. Publication of his plates as *The Birds of America*, to be issued in parts and financed by subscription, was finally undertaken by Robert Havell of London. From 1826 to 1839 his time was divided between Europe and the U.S., with his sons Victor and John as assistants, financing and overseeing publication and completing his projects by gathering material on trips, visiting collections, preparing illustrations and writing with the aid of William MacGillivray. The results were *The Birds of America*, with 435 hand-coloured folio plates (4 vol., 1827–38), the text to it, *Ornithological Biography* (5 vol., octavo, 1831–39), and what serves as an index, *A Synopsis of the Birds of North America* (1 vol., 1839).

Returning to the U.S. in 1839 he settled in New York, prepared a smaller edition of his *The Birds of America* (7 vol., octavo, 1840–44) and threw himself into preparing a new work, *Viviparous Quadrupeds of North America*, with the aid of his sons and that of John Bachman for the text. The plates were issued in 30 parts of five folio plates each (2 vol., 1845–46). The text, three octavo volumes, appeared in 1846–54. Audubon died Jan. 27, 1851.

Bibliography.—F. H. Herrick, *Audubon the Naturalist*, 2nd ed. (1938), the authoritative source, with full bibliography; *see* also *Audubon and His Journals* (1897), edited by Maria R. Audubon and Elliott Coues; and *Delineations of American Scenery and Character* (1926), with intro. by F. H. Herrick. (A. L. Rd.; X.)

AUE, a town of Germany which after the partition of the nation following World War II was located in the district of Karl-Marx-Stadt of the German Democratic Republic, is situated in the western Erzgebirge (Ore mountains) about 20 mi. S.E. of Zwickau on the Zwickauer Mulde river. Pop. (1964) 31,720. The frontier between the German Democratic Republic and Czechoslovakia is about 12 mi. S. of the town. After World War II Aue, in which there were metal, engineering and woven goods enterprises, became the centre of Erzgebirge uranium ore mining. Under the town and in its vicinity extensive deposits of pitchblende were discovered. The Zell Maria monastery was founded in 1173 and its Romanesque church is still standing. Aue received town rights in 1629.

AUENBRUGGER VON AUENBRUGG, LEOPOLD (1722–1809), Austrian physician, discoverer of percussion as a diagnostic procedure, was born in Graz on Nov. 19, 1722, the son of an innkeeper. He studied medicine in Vienna, received his M.D. degree and was appointed physician to the Spanish Military hospital. There he saw many patients with fluid in the chest, and, remembering his ability as a boy in his father's inn to judge the amount of wine in the casks by thumping their ends, he applied this method to the chest. He soon found that he could determine the amount of fluid and its location in the chest and the size of the heart as well. After seven years of investigation, Auenbrugger published in 1761 a description of the method and the results of his investigations in his *Inventum novum*, the first treatise on percussion in any language.

Auenbrugger's reputation as a physician grew, and he was raised to the nobility in 1784. The *Inventum novum*, however, received scant attention, and the method was generally ignored until in 1808, 47 years after its appearance, it was translated into French by Jean Nicholas Corvisart des Marets, personal physician to Napoleon. Corvisart not only translated the work but added his own observations and praised what he called Auenbrugger's beautiful and rightful discovery. It gained world-wide acceptance rapidly thereafter and remains a fundamental procedure in medical diagnosis. Auenbrugger died in Vienna on May 17, 1809.

See M. Neuburger, *Leopold Auenbrugger* (1922). (R. H. Mr.)

AUER, LEOPOLD (1845–1930), Hungarian-born violinist and teacher of many famous violinists. Born at Veszprém, June 7, 1845, he studied at Budapest and Vienna and later under Joseph Joachim at Hanover. In 1868 he was appointed professor of the violin at the St. Petersburg conservatory. He became a Russian subject in 1883. Between 1906 and 1914 he taught for periods in London and Dresden but continued to live at St. Petersburg. In 1917 he left Russia for Scandinavia and in 1918 settled in New York. Among his pupils were Mischa Elman, Jascha Heifetz, N. Milstein, T. Seidel and E. Zimbalist. He wrote *Violin Playing as I Teach It* (1921), *My Long Life in Music* (1923) and *Violin Master Works and Their Interpretation* (1925). He died at Loschwitz, near Dresden, July 17, 1930.

AUERBACH, BERTHOLD (1812–1882), German novelist, known for his tales of village life, was born at Nordstetten in the Black Forest on Feb. 28, 1812, and died at Cannes, France, on Feb. 8, 1882. He studied philosophy under David Strauss and Friedrich von Schelling. He was intended for the Jewish ministry, but was estranged from Jewish orthodoxy by the study of Spinoza and turned to literature. Spinoza's life formed the basis of his first novel (1837), and a translation of Spinoza's works followed in 1841. In 1843 he began publishing the *Schwarzwälder Dorfgeschichten* (Eng. trans., *Black Forest Village Stories*, 1869), and there later appeared novels in the same genre, among them *Barfüssele* (1856; Eng. trans., *Little Barefoot*, 1873) and *Edelweiss* (1861). These works found a wide public and many imitators. They are not realistic studies of rural life and owed some of their popularity to Auerbach's philosophical reflections and romanticism.

Bibliography.—The best edition of Auerbach's works is *Berthold Auerbachs Schriften*, 18 vol. (1893–95); *Auerbachs Briefe an seinen Freund J. Auerbach*, F. Spielhagen (ed.), was published in 2 vol. (1884). *See* also A. Bettelheim, *B. Auerbach* (1907); H. Graef, *B. Auerbach* (1907); M. G. Zwick, *B. Auerbachs sozialpolitischer und ethischer Liberalismus* (1933). (A. Gs.)

AUERSPERG, ANTON ALEXANDER, Graf von (1806–1876), Austrian poet who wrote under the pseudonym of Anastasius Grün and became known for his political poetry, was born at Laibach, Aus. (now Ljubljana, Yugos.), on April 11, 1806, and died at Graz, Aus., on Sept. 12, 1876. As a member of the estates of Carniola in the diet at Laibach, he was an outspoken critic of the Austrian government, and after 1848 he represented the district of Laibach for a short time at the German national assembly at Frankfurt, to which he tried in vain to persuade his Slovene compatriots to send representatives. In 1860 he was summoned to the remodeled *Verstärkter Reichsrat* by the emperor, who in 1861 nominated him a life member of the Austrian upper house (*Herrenhaus*). Count Auersperg's first publication was a collection of lyrics, *Blätter der Liebe* (1830). His second production, *Der letzte Ritter* (1830; Eng. tr., *The Last Knight*, 1871), celebrates the deeds and adventures of the emperor Maximilian I (1493–1519). But his fame rests almost exclusively on his political poetry. Two collections, entitled *Spaziergänge eines Wiener Poeten* (1831; "Promenades of a Viennese Poet," some of which were translated in K. Francke's *German Classics of the 19th and 20th Centuries*, 1913) and *Schutt* (1836), created a sensation in Germany by their originality and bold liberalism. His epics, *Die Nibelungen im Frack* (1843) and *Der Pfaff vom Kahlenberg* (1850), are characterized by a fine ironic humour. He also produced masterly translations of the popular Slovene songs current in Carniola (*Volkslieder aus Krain*, 1850) and of the English poems on Robin Hood (1864).

Bibliography.—L. A. Frankl (ed.), *Anastasius Grüns Gesammelte Werke*, 5 vol. (1877); B. von Frankl-Hochwart (ed.), *Briefwechsel mit L. A. Frankl* (1897); S. Hock (ed.), *Politische Reden und Schriften* (1906). *See* also P. von Radics, *Anastasius Grün*, 2nd ed. (1879); F. Riedl, *A. Grün Graf von Auersperg* (1909); R. Wächter, *A. Grüns politische Dichtung* (1933). (A. Gs.)

AUERSTÄDT, BATTLE OF, was fought by the French under Davout against the Prussians under King Frederick William III and Charles William Ferdinand, duke of Brunswick-Wolfenbüttel, on Oct. 14, 1806, at Auerstädt, in Saxony, 12 mi. N. of Jena, where Napoleon was simultaneously defeating the rest of the Prussian forces (*see* Napoleonic Wars). On Oct. 12, a week after setting out from the Bamberg region, Napoleon completed his outflanking movement against the Prussian army west of the Saale and closed in on that river line. His right wing, Davout and Bernadotte's corps, was to march north down the Saale while his main forces crossed around Jena to seek the enemy. The right wing thus stood ready either to head off a Prussian retreat to the Elbe or to deliver a flank attack if the enemy stood his ground west of Jena. As Lannes reached Jena, Davout entered Naumburg, 20 mi. downstream, within easy reach of the left bank roads leading from Weimar via Auerstädt toward the Elbe. On Oct. 13

the Prussians decided to retreat along this road, leaving a flank guard of 50,000 men near Jena, however, to follow on as a rear guard when the main army had passed Auerstädt, where it spent the night of Oct. 13. That afternoon Napoleon had mistaken the flank guard for the mass of the Prussian army and ordered up his corps for battle on Oct. 14. Bernadotte did not choose to march with Davout, as he should have done, and appeared on Napoleon's flank after the battle of Jena (6 A.M. to 4 P.M.). At 8 A.M. Davout's excellent III corps, 27,000 strong, appeared on the Weimar road in the path of 50,000 Prussians. He resisted their repeated and vigorous but piecemeal attacks with skill and determination, avoiding an attempt to outflank him and counterattacking when he could, to such effect that the Prussians began to retire at 12:30 P.M. Davout's troops had suffered casualties of 25% in this remarkable passage of arms and could not press the Prussian retreat strongly, but it became a rout when it was met by the fugitives from Jena. The Prussians lost 10,000 killed and wounded and 3,000 captured at Auerstädt. The next day the French began the most celebrated and successful pursuit of the Napoleonic wars. (J. H. N.)

AUGEAS (AUGEIAS or AUGIAS), in Greek legend, king of the Epeians in Elis, a son of Helios the sun-god. He possessed an immense wealth of herds, including 12 white bulls, sacred to Helios. Eurystheus imposed upon Hercules the task of clearing out all Augeas' stalls unaided in one day. This Hercules did by turning the Alpheus river through them. Augeas had promised him a tenth of the herd but then refused this, alleging that Hercules had acted only in the service of Eurystheus. Hercules thereupon led an army against him and finally slew Augeas and his sons.

AUGEREAU, PIERRE FRANÇOIS CHARLES, DUC DE CASTIGLIONE (1757–1816), French army officer, created marshal by Napoleon, was born in Paris on Oct. 21, 1757. His mother, a German, had a fruit shop and his father was a servant. For 16 years Augereau was an adventurer, moving from Russia to Portugal, twice deserting from French regiments and serving in several foreign armies; he knew several languages, was a master of both infantry and cavalry drill and small arms, and was tall, strong and intelligent. The French Revolution soon brought him into the extremist Jacobin party, which in 1793 sent him to Gen. J. A. Rossignol in the west and then suddenly transferred him to the eastern Pyrenees as general of a division. His discipline and care for his men made his division uniformly successful in Catalonia (1793–95) and later under Napoleon in Italy; his firmness turned the battle of Castiglione (Aug. 5, 1796) to victory, which Napoleon never forgot. But he was chosen to carry out the *coup d'état* of 18 Fructidor (Sept. 4, 1797) in Paris, and politics did him no good. He was rewarded with the command in Germany but was deprived of it three months later; he was elected deputy in 1799 and, having opposed Napoleon's *coup* of 18 Brumaire (Nov. 9, 1799), was kept from 1800 to 1805 in relatively minor commands, which he resented. Yet he was sixth of the marshals appointed in 1804.

In 1806 he was again, after nine years, directly under Napoleon, with a corps at the battle of Jena (Oct. 14). His health was broken in Poland. At the battle of Eylau (Feb. 8, 1807) his corps, misdirected in a snowstorm, lost half its numbers, and the marshal, strapped to his horse in his weakness, was badly hurt when it fell. For two years he was able to enjoy his wealth and his château of La Houssaye (Seine-et-Marne). Then, in 1809, he had to take the field, and he chose Catalonia. With 50,000 men he carried through the siege of Gerona, with immense losses from sickness. He then kept some state at Barcelona while his brother contended with the Catalan guerrillas. But Napoleon did not approve of his generals "residing in capitals" and recalled him (April 12, 1810). Preparations for the invasion of Russia in 1812 went on without him; then, at 12 days' notice, he was put in charge of Berlin, where he remained uneasily until Eugène de Beauharnais returned after the retreat from Russia. He was sent to Frankfurt, and by Oct. 1813 had enough conscripts to form a nominal corps. His men disappeared in the battle of Leipzig, from which he escaped with deep indignation against Napoleon. Yet in 1814 he was required to lead the "army of the east" to save Lyons from the Austrians. The emperor trusted to the "name" of his marshal. His small force, partly drawn from Spain, had some fighting, but Lyons was not saved, and the Bonapartists talked of treason. Augereau welcomed Louis XVIII in 1814, and his services were rejected by Napoleon in 1815. He received no command from Louis XVIII, but he was left untroubled in his home, where he died on June 12, 1816. *See* NAPOLEONIC WARS. (I. D. E.)

AUGHRIM (EACHDHRUIM), a small village in County Galway, Republic of Ireland, 99 mi. W. of Dublin by road. Pop. (1956) 121. It is famous for the decisive victory won there on July 22 (new style; July 12, old style), 1691, by the forces of William III under Gen. Heer van Ginkel (later 1st earl of Athlone) over those of James II under the French commander, the marquis de Saint-Ruth, who fell in the fight. The Irish, numbering about 25,000 and strongly posted behind marshy ground, at first maintained a vigorous resistance, but Ginkel penetrated their line of defense, and their general was struck down by a cannon ball at this critical moment. They were overcome and routed with terrible slaughter. The English loss did not exceed 700 killed and 1,000 wounded; while the Irish, in their disastrous flight, lost about 7,000 men and all their military equipment. This defeat was followed by the complete submission of Ireland in October.

AUGIER, (GUILLAUME VICTOR) ÉMILE (1820–1889), French dramatist, shared with Dumas *fils* and Victorien Sardou the mastery of the French stage during the second empire. He was born at Valence, Drome, on Sept. 17, 1820, of wealthy middle-class parents. A disciple of Balzac, he tried to do for the drama what Balzac had done for the novel. While all his plays are to some extent didactic in purpose, this aspect is particularly evident in *Madame Caverlet* (1876) and in *Les Fourchambault* (1878), his last play and one of his best. An unbending moralist, Augier had already in 1849, with a verse-play, *Gabrielle*, challenged the romantic belief in the divine right of passion. Then in 1855, in the harshly realistic *Le Mariage d'Olympe*, he refuted the romantic thesis of the rehabilitation of the prostitute by love, put forward in Dumas's *La Dame aux camélias*. A champion of the institution of marriage, Augier satirized venal adultery in *Les Lionnes pauvres* (1858) and saw in greed, and in money itself, the root of all evil. His best-known play, *Le Gendre de Monsieur Poirier* (1854), which was based on Jules Sandeau's novel *Sacs et parchemins* and written in collaboration with Sandeau, advocated the fusion of the new prosperous middle class and the dispossessed nobility. Augier died at Croissy on Oct. 25, 1889.

See H. Gaillard de Champris, *Emile Augier et la comédie sociale* (1910). (D. Ks.)

AUGITE, a widespread aluminous monoclinic pyroxene mineral, occurs as a major constituent in basic rocks, notably gabbros, pyroxenites and basalts. Augite has been found in meteorites and occurs in slags. Well-developed crystals of augite are common in the Hawaiian basalts. The minerals most commonly found with augite are olivine, orthorhombic pyroxene, amphibole, plagioclase (usually of about labradorite-bytownite composition) and, in some rocks, biotite is common. Several varieties of augite are distinguished; those rich in titanium are called titanaugites and those rich in sodium are called aegerinaugites. Aegerinaugite is found in the alkaline-rich nephaline syenites and leucite-bearing lavas. For further discussion of the occurrence of augite *see* BASALT; GABBRO; PYROXENITE. *See* also ANDESITE; DIABASE; RHYOLITE; TRACHYTE.

The composition of augite, a mixture of aluminum, magnesium, calcium and iron silicates, is variable (*see* PYROXENE); it is best visualized as a solid solution dominantly composed of the $Ca(Mg,Fe)(SiO_3)_2$ series with a limited amount of the $(Mg,Fe)SiO_3$ series plus some aluminum in substitution for both the Si and Mg-Fe atoms in the mineral. Pigeonite is the pyroxene corresponding to augite composed dominantly of the $(Mg,Fe)SiO_3$ series with limited amounts of the $Ca(Mg,Fe)(SiO_3)_2$ series. A gradation between augite and pigeonite is possible.

It is difficult to distinguish augite from the other monoclinic pyroxenes even under the microscope; therefore the term augite is often used as a general term for the monoclinic pyroxenes. In general, the augites are dark green, brown or black in colour.

The complete alteration of augite crystals to an amphibole is rather common and the term uralite or the process uralitization has been given to such occurrences. Alteration to chlorite, talc and serpentine also can occur. (G. W. DeV.)

AUGSBURG, a town of Germany which after partition of the nation following World War II was located in the *Land* of Bavaria, Federal Republic of Germany, lies at the junction of the Wertach and Lech rivers and extends over the plateau country between them. Pop. (1961) 208,659.

The street system of the northern part of the town centres on the cathedral, the west end and crypt of which were built between 944 and 1006 and the Gothic nave between 1331 and 1343. The interior was restored in 1934. The cathedral's chief monuments are the 11th-century bronze doors, the five Romanesque stained-glass windows in the nave, the bishop's throne supported by lions and the altar pieces painted by Hans Holbein the Elder and Christoph Amberger. St. Ulrich's church, at the southern end of the main street from the cathedral, was begun in 1467 by Burkhard Engelberg and completed two centuries later. It contains a Late Gothic statue of the Madonna (*c.* 1500), stained-glass windows in the vestry and a baroque wrought-iron gate (1712). The town hall, in the centre of the town, was built between 1615 and 1620 by Elias Holl, but it was almost completely burned out and its famous "Golden Hall" destroyed during World War II. The main street contains three 16th-century fountains and there is a town museum, two art galleries and a municipal library with a collection of archives, manuscripts, drawings, etc. The house of Leopold Mozart, father of the composer, is now a Mozart museum. Augsburg has an open-air theatre, a sports stadium, and a zoo and botanical garden in the Siebentisch park. Educational establishments include three colleges of music including one named after Leopold Mozart, a philosophy school and the Rudolph Diesel polytechnic, named after the inventor of the diesel engine.

Augsburg, situated on the Frankfurt-Salzburg *autobahn*, is at the junction of several main railway and long-distance bus routes. Munich airport is 40 mi. distant. As an industrial centre, Augsburg is among the most important in southern Germany. There are heavy engineering, textiles, tin, metal, chemical and electrical industries, as well as factories for cars, airplanes, paper and shoes. Many of the manufactured goods are exported, particularly diesel engines and printing machinery.

Signs of an Early Bronze Age settlement have been traced in the southern part of the town. Founded as a Roman colony (Augusta Vindelicorum), by Drusus in 15 B.C., on a triangular piece of ground at the junction of the Lech and Wertach, the Roman town belongs to the reign of the emperor Tiberius. Augsburg must already have been the seat of a bishop in the 7th century. Under Bishop Ulrich the Hungarians were decisively defeated by King Otto in 953 on the Lechfeld to the south of the town. Augsburg became a free imperial city in 1276 and in 1331 joined the Swabian league (*see* SWABIA). The business houses, headed by those of the Fugger (*q.v.*) and the Welser families, were responsible, in the first half of the 16th century, for the vigorous economic development of the town with which was associated the encouragement of both art and science. Hans Holbein the Elder and the Younger and Hans Burgkmair (*qq.v.*) were natives of the town. At the imperial diet of Augsburg in 1530, the Augsburg Confession was read and the League of Augsburg was decided in 1686. Though considerably damaged during World War II, Augsburg retains much of its former beauty. (H. F. De.)

AUGSBURG, PEACE OF, the first permanent legal basis for the existence of Lutheranism as well as Catholicism in Germany, promulgated on Sept. 25, 1555, as part of the recess, or final resolution of the diet of the Holy Roman empire assembled earlier that year at Augsburg.

The emperor Charles V's provisional ruling on the religious question (*see* REFORMATION), namely the Augsburg Interim of 1548, had been overthrown four years later by the revolt of the Protestant elector Maurice of Saxony and his allies. In the ensuing negotiations at Passau (summer 1552) even the Catholic princes had called for a lasting peace, for fear that otherwise the religious controversy would never be settled. The emperor, however, was unwilling to recognize the religious division in western Christendom as permanent and granted a peace only until the next imperial diet.

The diet, which opened at Augsburg on Feb. 5, 1555, was indeed proclaimed by Charles V, but, as he did not wish to lend himself to the inevitable religious compromises, he refused to take part in the proceedings and empowered his brother Ferdinand (the future emperor Ferdinand I) to settle all questions. The diet determined that in future no member of the empire should make war against another on religious grounds and that this peace should remain operative until the denominations were peacefully reunited. Only two denominations were recognized—the Roman Catholics and the adherents of the Augsburg Confession, in other words the Lutherans. Moreover, in each territory of the empire only one denomination was to be recognized, the religion of the prince's choice being thus made obligatory for his subjects; any who adhered to the other could sell their property and migrate to a territory where it was recognized. Those free and imperial cities which had lost their religious homogeneity a few years earlier were exceptions to the general ruling, Protestant and Catholic citizens in them remaining free to exercise their religion as they pleased. The same freedom was furthermore extended to Protestant knights, towns and other communities who had for some time been practising their religion in the lands of ecclesiastical princes of the empire. This last concession provoked vehement Catholic opposition, and Ferdinand circumvented the difficulty by deciding the matter on his own authority and including the clause in a separate article, the *Declaratio Ferdinandea*.

Ecclesiastical lands taken by Lutherans from prelates who were not immediate vassals of the emperor were to remain with the Lutherans if continuous possession could be proved from the time of the treaty of Passau (Aug. 2, 1552), but to ensure the permanence of the remaining ecclesiastical territories, the Catholics gained the condition that in future any ecclesiastical prince who became Protestant should thereupon renounce his office, lands and revenues. Since the Protestants would not accept this so-called ecclesiastical reservation (*reservatum ecclesiasticum*) and the Catholics would not yield, Ferdinand incorporated the clause in the recess on his own authority with a note that agreement had not been reached on it. In fact Protestants were in many cases able to nullify its effect.

The wish for a lasting settlement was so strong that the compromise peace, which satisfied no one completely and had many loopholes, was accepted. In spite of its shortcomings, the peace of Augsburg saved the empire from serious internal conflicts for more than 50 years.

There is a critical edition of the text of the peace of Augsburg with that of the royal declaration, by K. Brandi, *Der Augsburger Religionsfriede vom 25. September 1555*, 2nd ed. (1927).

Hartung, *Deutsche Verfassungsgeschichte vom 15. Jahrhundert bis zur Gegenwart*, 7th ed. (1959). (E. H. H.)

AUGSBURG, WAR OF THE LEAGUE OF, a name sometimes bestowed, rather mistakenly, on the War of the Grand Alliance (*q.v.*). The League of Augsburg, which was formed on July 9, 1686, between the Holy Roman emperor Leopold I and certain princes and states of the empire (the kings of Spain and of Sweden were members only as holders of imperial fiefs) against the threat of French aggression, neither provoked war nor comprised those states which, after the French invasion of the Palatinate in Sept. 1688, were to be the emperor's most effective allies.

AUGSBURG CONFESSION (Lat. *Confessio Augustana* the Lutheran Reformation's basic particular creed, was presented June 25, 1530, at the diet of Augsburg in equally authoritative German and Latin versions to the emperor Charles V by seven Lutheran princes and two imperial free cities. The chief author was Philipp Melanchthon (*q.v.*), who utilized earlier Lutheran statements of faith. The purpose was to defend the Lutherans against current misrepresentations and to provide a statement of their theology that would be acceptable to the papalist party in

the Holy Roman empire.

The Confession contains 28 articles. The first 21 (on the Trinity, original sin, Christ, forgiveness of sins, the ministry, the new obedience, the church, the objective efficacy of the sacraments, baptism, the Eucharist, private confession, repentance, the use of the sacraments, ecclesiastical order, church rites, civil affairs, eschatology, free will, the cause of sin, faith and good works, the cult of the saints) set forth the Lutherans' over-all doctrine with a view to demonstrating that "they dissent in no article of faith from the Catholic Church." The remaining seven articles discuss "abuses" that had crept into the Western Church in the centuries immediately preceding the Reformation and that the Lutherans had corrected in their domains—communion under one kind, enforced priestly celibacy, the Mass as an expiatory sacrifice, compulsory confession, human institutions designed to merit grace, abuses in connection with monasticism, and the expanded authority claimed by the bishops. On Aug. 3 the theologians of the papalist party replied with the so-called Confutation. The emperor refused to receive a Lutheran counter-reply offered on Sept. 22; but it formed the basis for Melanchthon's "Apology of the Augsburg Confession" (1531).

While the "unaltered" 1530 version of the Augsburg Confession has always been authoritative for Lutherans, proponents of the eucharistic doctrines of Zwingli and Calvin within the Holy Roman empire widely received a modified edition (the "Variata" of 1540), with an ambiguously worded article x.

Richard Taverner translated the Augsburg Confession into English in 1536; its subsequent influence on the Anglican Thirty-Nine Articles and John Wesley's Twenty-Five Articles is clearly traceable. *See* also Confessions of Faith, Protestant: *Lutheran Churches.*

Bibliography.—Critical texts, plus bibliography, of the Augustana and the Apology by Heinrich Bornkamm in Hans Lietzmann (ed.), *Die Bekenntnisschriften der evangelisch-lutherischen Kirche herausgegeben im Gedenkjahr der Augsburgischen Konfession 1930*, 4th ed. (1959); English translations in Theodore G. Tappert *et al.* (eds.), *The Book of Concord* (1959). For the "Confutation" in English, *see* (Johann) Michael Reu, *The Augsburg Confession* (1930). (A. C. Pn.)

AUGUR, in ancient Rome, one of the members of a religious college whose duty it was to observe and interpret the signs (*auspices*) of approval or disapproval sent by the gods in reference to any proposed undertaking. The *augures* were originally called *auspices*, but, while *auspex* fell into disuse and was replaced by *augur*, *auspicium* was retained as the scientific term for the observation of signs. Auspex = *avispex*, "observer of birds"; *augur* probably is to be connected with the root of *augere, augustus*. It seems therefore originally to have meant an expert in fertility magic rather than a diviner.

The early history of the college is obscure. Its institution has been attributed to Romulus or Numa. It probably consisted originally of three members, of whom the king himself was one. This number was doubled by Tarquinius Priscus, but in 300 B.C. it was only four, two places, according to Livy, being vacant. The Ogulnian law in the same year increased the number to nine, five plebeian being added to the four patrician members. In the time of Sulla the number was 15, which was increased to 16 by Julius Caesar. This number continued in imperial times, and the college itself was certainly in existence as late as the 4th century A.D. The office of augur, which was bestowed only upon persons of distinguished merit and was much sought after by reason of its political importance, was held for life. Vacancies were originally filled by co-optation, but by the Domitian law (104) the selection was made, by 17 out of the 35 tribes chosen by lot, from candidates previously nominated by the college. The insignia of office were the lituus, a staff free from knots and bent at the top, and the trabea, a kind of toga with bright scarlet stripes and a purple border.

The science of augury was contained in various written works, including a manual of augural ritual, and a collection of answers given by the college to the senate. The natural region to look to for signs of the will of Jupiter was the sky, where lightning and the flight of birds seemed directed by him as counsel to men. It was the duty of the augur, before the auspices properly so called (those from the sky and from birds) were taken, to mark out with his staff the *templum* or consecrated space within which his observations were intended to be made. At midnight, when the sky was clear and there was an absence of wind, the augur, in the presence of a magistrate, took up his position on a hill that afforded a wide view. After prayer and sacrifice, he marked out the *templum* both in the sky and on the ground and dedicated it. Within its limit he then pitched a tent, in which he sat down with covered head, asked the gods for a sign, and waited for an answer. As the augur looked south he had the east, the lucky quarter, on his left, and therefore signs on the left side were considered favourable, those on the right unfavourable. The practice was the reverse in Greece; the observers of signs looked toward the north, so that signs on the right were regarded as the favourable ones; this practice was frequently adopted in the Roman poets. The augur afterward announced the result of his observations in a set form of words, by which the magistrate was bound.

Signs of the will of the gods were of two kinds, either in answer to a request (*auspicia impetrativa*), or incidental (*auspicia oblativa*). Of such signs there were five classes:

1. Signs in the sky, consisting chiefly of thunder and lightning, but not excluding falling stars and other phenomena. Lightning from left to right was favourable, from right to left unfavourable; but on its mere appearance, in either direction, all business in the public assemblies was suspended for the day. Since the person charged to take the auspices for a certain day was constitutionally subject to no other authority who could test the truth or falsehood of his statement that he had observed lightning, this became a favourite device for putting off meetings of the public assembly. Restrictions were imposed, however, in later republican times. When a new consul, praetor or quaestor entered on his first day of office and prayed the gods for good omens, it was a matter of custom to report to him that lightning from the left had been seen.

2. Signs from birds, with reference to the direction of their flight and also to their singing or uttering other sounds. To the first class belonged the eagle and the vulture, to the second the owl, the crow and the raven. The mere appearance of certain birds indicated good or ill luck, while others had a reference only to definite persons or events. In matters of ordinary life on which divine counsel was prayed for, it was usual to have recourse to this form of divination. For public affairs it was superseded, by the time of Cicero, by the fictitious observation of lightning.

3. Feeding of birds, which consisted in observing whether a bird—usually a fowl—when grain was thrown before it, let fall a particle from its mouth. If it did so, the will of the gods was in favour of the enterprise in question. The simplicity of this ceremony recommended it for very general use, particularly in the army when on service.

4. Signs from animals—*i.e.*, observation of the course of, or sounds uttered by, quadrupeds and reptiles within a fixed space—corresponding to the observations of the flight of birds, but much less frequently employed.

5. Warnings, consisting of all unusual phenomena, but chiefly such as boded ill. Such were various noises, the fall of a stick in a temple, the squeak of a mouse, stumbling, sneezing or the seizure of anyone in the comitia by an epileptic fit. Being accidental in their occurrence, they belonged to the *auguria oblativa*, and their interpretation was rather a matter for the *pontifices* than for the augurs, when the incident was not already provided for by a rule.

Among the other means of discovering the will of the gods were the casting of lots, Sibylline oracles (in the hands of the college *sacris faciundis*), and, more commonly, the examination of the entrails of animals slain for sacrifice. Anything abnormal found there was brought under the notice of the augurs, but usually the Etruscan haruspices (*q.v.*) were employed for this. The persons entitled to ask for an expression of the divine will on a public affair were the magistrates. To the highest offices, including all persons of consular and praetorian rank, belonged the right of taking *auspicia maxima*; to the inferior offices of aedile and quaestor, the *auspicia minora*; the differences between these, however, must have been small. The subjects for which *auspicia publica* were always taken were the election of magis-

trates, their entering an office, the holding of a public assembly to pass decrees, and the setting out of an army for war. They could be taken only in Rome itself; and in case of a commander's having to renew his auspices, he must either return to Rome or select a spot in the foreign country to represent the hearth of that city. The time for observing auspices was, as a rule, between midnight and dawn of the day fixed for any proposed undertaking. The founding of colonies, the beginning of a battle, the calling together of an army, sittings of the senate and decisions of peace or war frequently were occasions for taking auspices. The place where the ceremony was performed was not fixed but selected with a view to the matter in hand. A spot being selected, the official charged to make the observation pitched his tent there several days before. A matter postponed through adverse signs from the gods could on the following or some future day be again brought forward for the auspices. If an error occurred in the auspices, the augurs could, of their own accord or at the request of the senate, inform themselves of the circumstances and advise upon it. A consul could refuse to accept their advice while he remained in office, but on retiring he could be prosecuted. *Auspicia oblativa* referred mostly to the comitia. A magistrate was not bound to take notice of signs reported merely by a private person, but he could not overlook such a report from a brother magistrate. For example, if a quaestor on his entry to office observed lightning and announced it to the consul, the latter must delay the public assembly for the day.

AUGUST (Lat. *Augustus*), the eighth month of the modern calendar, with 31 days. In the early Roman calendar, which began with March, it was the sixth month and was hence called Sextilis, a name it retained until the year 8 B.C., when the emperor Augustus allowed it to be renamed in his honour. The feast of the Assumption of the Virgin (Dormition of the Virgin in the Orthodox Eastern Churches) is celebrated on August 15.

(F. R. WN.)

AUGUSTA, a town of Sicily, province of Siracusa, lies on a long sandy island off the southeast coast, connected by two bridges with the mainland, 48 km. (30 mi.) N. of Syracuse by road. Pop. (1957 est.) 25,437 (commune). The 17th-century cathedral was rebuilt in 1769 after a severe earthquake. The main industry is agriculture—the area being very rich in cereals, olive orchards, vineyards and market gardens. Salt mining is carried on along the coast, also fishing and the preserving of anchovy. The name of the town is not derived from Augustus, as it was founded in 1232 by the emperor Frederick II for the rebellious people of Centuripe and Montalbano, which towns were destroyed because of their disaffection. Frederick called it Augusta Veneranda and it became one of his favourite resorts. It was chosen by the Sovereign Order of the Knights of Malta to be its supply repository at the beginning of the 19th century. In 1860 Augusta became part of the kingdom of Italy and in World War II was one of the ports of disembarkation of the Anglo-American forces for the invasion of Italy on July 10, 1943. (M. T. A. N.)

AUGUSTA, a city of Georgia, U.S., 171 mi. S.E. of Atlanta, at the head of navigation on the Savannah river; seat of Richmond county. It is an inland port on the Savannah river, 90 mi. from the seaport of Savannah.

Population (1960), city 70,626; standard metropolitan statistical area (Richmond county in Georgia and Aiken county in South Carolina), 216,639. The metropolitan area includes the cities of North Augusta and Aiken, S.C. (For comparative population figures *see* tables in GEORGIA: *Population* and SOUTH CAROLINA: *Population.*)

The first white men to visit the area near the present site of Augusta were Spaniards, under the leadership of Hernando de Soto in 1540. In the early years of the 18th century the inland region of the Savannah river attracted the English fur trader before the colony of Georgia was established, and the lucrative trade in pelts was a major factor in the decision of James Edward Oglethorpe, founder of the Georgia colony, to establish a trading post (1735) on the west bank of the river. The settlement was named Augusta in honour of Princess Augusta, mother of George III, king of England.

The fur trade increased not only by means of the river facilities but also along the road that was built in 1740 to connect Savannah with Augusta. Friendly relations with the Indians were important in the growth of the new settlement. In 1763 Cherokees, Choctaws, Creeks, Chickasaws and Catawbas met the governors of Georgia, South Carolina, North Carolina and Virginia at Augusta and agreed to recognize definite boundaries for the Georgia colony. In 1773, at Augusta, Creeks and Cherokees ceded approximately 2,100,000 ac. of land to the Georgia authorities.

At the beginning of the American Revolution, the prevailing temper of Augusta was loyalist, but revolutionary sentiment soon prevailed and the patriots gained control. George Walton, of Augusta, was one of the three Georgia signers of the Declaration of Independence. When Savannah was attacked by the British in 1778, Gov. John Houstoun and his council fled inland to the Savannah river city. The British seized Augusta within a month and the patriot government was forced to abandon the city. In Feb. 1779 a group of patriots led by Elijah Clarke, John Twiggs and John Dooly dispersed a British army and forced the British to move out of the city, but after the fall of Charleston, S.C., in May 1780, the British reoccupied and retained control of the city until June 1781.

Augusta was the capital of Georgia from 1786 to 1795, and there on Jan. 2, 1788, a state convention ratified the constitution of the United States. The town was incorporated in 1789 and given a charter in 1798.

The "Genius of Georgia," a ship propelled by 19 horses walking on an endless belt, made its first trip from Savannah up the river to Augusta in 1820. The Charleston and Hamburg railroad reached the Savannah river opposite the city in 1833. In 1841 the Georgia railroad connecting Augusta and Athens was completed and the Central railroad of Georgia joined Augusta to Savannah in 1854.

When Georgia seceded from the union in 1861, U.S. troops continued to occupy the Augusta arsenal which had been a federal post since 1819. However the arsenal was soon surrendered to Confederate forces. During the Civil War, Augusta was the ordnance centre of the Confederacy.

In the period following the Civil War the city figured prominently in the industrial development of the new south. It became a major cotton centre, and textile manufacturing became the principal industry. Augusta is situated in the heart of rich clay deposits, and its industries include the manufacture of bricks, tile and fine kaolin (used in the making of porcelain). Major features of the comprehensive federal program for the development of the Savannah river basin were to make Augusta a 12-month barge port with a minimum year-round channel of 9 ft., to protect the city and the area along the river from the recurrent danger of floods and to provide low-cost hydroelectric power to the area.

Augusta's Academy of Richmond county, chartered by the state in 1783, is one of the oldest high schools in the United States. The University of Georgia school of medicine, founded in 1828 as the Medical Academy of Georgia, occupies a 45-ac. tract in the city. Paine college (founded as Paine institute, 1883) is an institute for Negroes supported by the Methodists. Augusta college, a junior college, organized in 1925, became a part of the university system of Georgia in 1958.

Fort Gordon, a training school for military police, the signal corps and the corps of engineers, is located about 8 mi. from Augusta.

Augusta, termed "The Winter Golf Capital of America," is the home of the Augusta National Golf course, designed by Bobby Jones and Alistair McKenzie, where the Masters Invitational golf tournament is played annually.

There are many buildings of historic interest: St. Paul's Episcopal church (founded in 1750), the First Presbyterian church (1804) and the manse where Woodrow Wilson spent his boyhood, the Augusta arsenal, established in 1819; and the chimney of the Confederate powder mill, which was the principal source of supply

for the Confederate army. A Celtic cross in St. Paul's churchyard marks the site of Ft. Augusta, built by James Oglethorpe in 1735. It was near Augusta that Eli Whitney set up and operated his first cotton gin. On upper Broad street stands the "White House," now the home of the Augusta-Richmond County Historical society and a museum for relics of the Revolutionary period. (J. N. A.)

AUGUSTA, the capital of Maine, U.S., is a small city at the head of navigation on the Kennebec river, about 60 mi. N.E. of Portland; the shire town of Kennebec county.

Augusta owes its establishment and early growth to its location on navigable tidewater, 40 mi. from the Atlantic ocean. Augusta's recorded history began with the arrival of traders from the Plymouth colony of Massachusetts in 1628. On a site the Canibas Indians called Koussinoc, they established a trading post which became one of the most important on the Atlantic seaboard in early colonial days. John Howland and John Alden were agents there and Capt. Myles Standish made a number of visits to the post. The first permanent structure, Ft. Western, was built there in 1754. In 1919 the fort was restored as a historic monument. In 1797 the settlement was incorporated as the town of Harrington; the name was changed to Augusta later that year. Two years later Augusta became the shire town of Kennebec county.

Augusta became the state capital in 1831, and was incorporated as a city in 1849. In 1959 a council-manager form of government became effective.

Many of Augusta's inhabitants are descended from early English settlers, and many others are of French-Canadian origin. Although a large number of its residents are employed in government service, many are employed in the city's industries, which include the manufactures of cotton textiles, paper, shoes and food products. The city is the commercial centre of a large agricultural area producing apples, garden crops and poultry.

The state capitol, a native granite structure begun in 1829, has been remodeled several times, but retains its original façade designed by Charles Bulfinch in 1829. Nearby is Blaine house, now the governor's residence, formerly the home of James G. Blaine.

A 2,100-ft. bridge of cantilever deck truss design, spanning the Kennebec river in the heart of the city, was completed in 1950. The Kennebec dam (first built in 1837) is head of tide. With the Belgrade chain of lakes 15 mi. N. and the Kennebec river reaching 40 mi. S. to the sea, Augusta is one of the more important summer vacation centres in Maine.

For comparative population figures *see* table in MAINE: *Population.* (R. M. Cr.)

AUGUSTAN HISTORY (*Historia Augusta*), the name now given to a collection of biographies of the Roman emperors (*Augusti*) from Hadrian to Numerian (A.D. 117–284), including associate emperors (*Caesares*) and usurpers. The manuscripts are entitled *Vitae diversorum principum et tyrannorum a Divo Hadriano usque ad Numerianum a diversis compositae;* but the original title is uncertain. The work is mutilated. It lacks the preface, and one cannot be sure whether or not it began with Nerva and Trajan, in continuation of Suetonius' *De vita Caesarum;* the lives of Philip, Decius, Gallus, Aemilian (which fall between 244 and 253) and part of Valerian's life are also missing. Six authors are mentioned: Aelius Spartianus, Julius Capitolinus, Vulcacius Gallicanus, Aelius Lampridius, Trebellius Pollio and Flavius Vopiscus; and dedications to Diocletian and Constantine suggest that they wrote between 284 and 337. Yet, although a case can be made for this dating, the work betrays anachronistic details and reflects political and literary attitudes of the middle or late 4th century, when the pagan traditions revived in reaction to Christianity. It is possible now to go farther than the great German scholar Theodor Mommsen, who assumed that there was an original edition of the time of Diocletian and Constantine, which, he thought, had then been revised, first about 330 and again under Valentinian and Theodosius I (364–395). If the work as a whole is later, the names of authors have to be rejected as spurious, and the question of authorship—whether by one or more writers—remains open. H. Dessau established this approach to the composition of the *Historia Augusta* and concluded that it was the work of one man, writing about 380–395, under Theodosius. In any event it can hardly be later than 409–410. But N. H. Baynes has made a strong case for regarding the work as a propaganda piece written in 362–363 in favour of Julian the Apostate.

The *Historia Augusta* is a work of considerable importance, if only because it is frequently the sole source of information; but it must be handled critically. After allowing for the spurious elaboration of its final form, it can be seen that the narrative falls into two parts of differing historical value. The first part—from Hadrian to Caracalla—contains authentic material from an imperial chronicle and biographies of the emperors and shows sound knowledge of the public administration; much of this may rest upon the authority of Marius Maximus, who in the early 3rd century continued Suetonius in a series of biographies of emperors from Nerva to Elagabalus. The second part—from Geta to Numerian—followed Greek historians of the 3rd century, among whom may be mentioned Dexippus, and (it is widely held) made direct use of the *De Caesaribus* of Aurelius Victor (A.D. 360), which would date the composition after this year, whether immediately under Julian or later under Theodosius. It has also been related to the work of Eutropius (*q.v.*), who wrote under Valens (364–378); but whether this means direct use of Eutropius, which would exclude composition under Julian, or of a lost biographical source of Eutropius, which would permit the dating under Julian, is a matter of dispute. In any event, this part of the *Historia Augusta* betrays spurious elaboration where sound material was lacking; for the alleged extracts from public documents, *e.g.*, emperors' letters and senatorial decrees, are open to serious doubt, so many being palpable forgeries as to create a prejudice against all. Despite its historical deficiencies the work stands in the tradition of imperial biography, as this was adapted to the interests of cultivated pagan circles in Rome during the 4th century. Not only Julian the Apostate but leading senatorial families opposed the glorification of Rome as the city of St. Peter, and they aimed at reviving the old national conception of the Roman empire. If the *Historia Augusta* is taken to be later than Diocletian and Constantine, it gains authority by claiming to belong to the last period of greatness under dynasties founded upon pagan divine right.

AUGUSTINE, SAINT, OF CANTERBURY (d. *c.* 607), the founder of the Christian church in southern England, and first archbishop of Canterbury. He was a monk in the monastery of St. Andrew in Rome when Gregory I chose him to be the leader of a mission to England, then largely pagan, as the British Christians had retreated to the west and the north since the Anglo-Saxon invasions. On the way the group lost heart and sent Augustine back to Rome, where however he was encouraged by the pope with letters of commendation (596) and set out once more. He landed in Thanet with his monks early in 597 and was well received by Aethelberht, king of Kent, who gave them a dwelling place in Canterbury and allowed them to preach. Augustine at first used the ancient church of St. Martin, where Queen Berhta, a Christian from France, and her chaplain, the Frankish bishop Liudhard, were accustomed to worship. Aethelberht supported the mission, and in the autumn of 597 Augustine was consecrated bishop by Virgilius at Arles. In 601 he received the pallium from Gregory and was given authority over the bishops in Britain. He consecrated Christ Church, Canterbury, and built the monastery of

SS. Peter and Paul, later known as St. Augustine's. At a conference with British bishops he tried in vain to bring about a union between the British (Celtic) churches of north Wales and the churches he was founding. In 604 he consecrated Mellitus as bishop of London and Justus as bishop of Rochester. Augustine died probably before Easter, 607. His feast day is May 28.

See F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947).

(PL. GN.)

AUGUSTINE, SAINT, OF HIPPO (AURELIUS AUGUSTINUS) (A.D. 354–430), bishop of Hippo in Roman Africa from 396 to 430, and in his own day the dominant personality of the Western Church, is generally recognized as the greatest thinker of Christian antiquity. His mind was the crucible in which the religion of the New Testament was most completely fused with the Platonic tradition of Greek philosophy; and it was also the conduit by which the product of this fusion was transmitted to the Christendoms of medieval Roman Catholicism and Renaissance Protestantism. This unique significance would have belonged to Augustine had he never written the famous *Confessions*, in which at the age of about 45 he told the story of his own restless youth and of the stormy voyage that had ended, as he believed, 12 years before he put it in writing, in the haven of the Catholic Church. It is easy to forget that the real work of Augustine's life did not begin until the last scene of the *Confessions* was already receding for him into a remembered past. Moreover, the *Confessions* themselves are not so much autobiography as devotional outpourings of penitence and thanksgiving. Augustine's conscientious memory generally can be trusted for the facts; his reflections upon them are those of the bishop on his knees. This is not to say that, in any attempt to understand or appreciate the mind of the bishop, the *Confessions* can be neglected. The picture must be drawn in proper proportion; it is essential to avoid giving undue prominence to what should be no more than its background.

Youth and Conversion.—Hippo Regius is the modern Bône on the Algerian coast, in what was then the Roman province of Numidia. Augustine was born on Nov. 13, 354, of middle-class parents at Tagaste, the modern Souk-Ahras, a small town about 45 mi. to the south. His father, Patricius, was and remained until late in life a pagan; his mother, Monica, was a Christian of intense but simple piety, from whose early teaching Augustine retained a reverence for the "name of Christ" that never left him. But like many another child of Christian parents in those days he was not baptized in infancy. He went through the usual primary and secondary schooling, and soon displayed such intellectual promise that the modest family funds were banked upon securing him an academic career such as might qualify him for government service. As an 18-year-old student at Carthage he was profoundly stirred, by the reading of a treatise of Cicero (the now lost *Hortensius*), with an enthusiasm for "philosophy," which meant not only a devotion to the pursuit of truth but a conviction of the superiority of the life so devoted (the *vita contemplativa*) over any aims of secular ambition. The faith of the Catholic Church indeed seemed to him too hopelessly unphilosophical for any man of culture to entertain; but he was easily carried away by the discovery in Manichaeism (*q.v.*) of a religion that professed to appeal to reason rather than authority.

The Manichaean system as propagated in the Western empire was a materialistic dualism, accounting for the world as the product of a premundane conflict of light and dark substances, and for the soul of man as an element of the light entangled in the dark. Manichaeism claimed to be the true Christianity, preaching Christ as the Redeemer who enables the imprisoned particles of light to escape and return to their own region. In the Manichaean Church the higher order of "elect" were strictly ascetic and celibate, all physical generation being held to serve the realm of darkness. Augustine joined its lower order as one of the "hearers," to whom marriage was permitted as a concession to human weakness. For, after an adolescence that probably was no more licentious than was common in his time and country, he had formed a liaison with a woman of low birth to whom he remained loyally attached throughout the nine years of his association with the Manichaeans. But his first zeal for this "religion of enlightenment" did not last long. The Manichaean experts, intellectually second-rate, proved incapable of dealing with the questions he put to them. He became increasingly disillusioned, and was already falling into a general agnosticism when, at the age of about 28, he left Carthage, where he had worked as a free-lance teacher of rhetoric, and went to Rome in search of more satisfactory pupils. There he made connections that procured for him the appointment to an official professorship at Milan, then the place of residence of the emperor of the west. The bishop of Milan was Ambrose, the most eminent Christian leader of the day (*see* AMBROSE, SAINT). Augustine was introduced to but never became intimate with him. He went to hear him preach, however, and this, his first contact with the mind of a Christian intellectual, was enough to shake his prejudice against Catholic teaching. But though he had abandoned the doctrines of Manichaeism, he retained its materialistic presuppositions, which left him still a skeptic with no satisfying alternative to Manichaean notions of ultimate reality. The being of God and the nature and origin of evil were problems as insoluble as ever.

The solution of both was given to him by a chance introduction to Neoplatonic writings, for which he may well have been prepared by Ambrose's use of them in some of his sermons. Neoplatonism (*q.v.*), in the work of Plotinus, its greatest exponent, is a spiritual monism according to which the universe exists as a series of emanations or degenerations from absolute unity. From the transcendent One arises self-conscious mind or spirit; from mind comes soul or life, and soul is the intermediary between the spheres of spirit and of sense. Matter is the lowest and last product of the supreme unity; and since the One is also the real and the good, the potentiality of evil is identified with unformed matter as the point of maximum departure from the One. Evil itself is thus the least real of all things, being simply the privation or absence of good. Neoplatonic mysticism relies on the principle that the inward is superior to the outward: to reach the good, which is the real, we must "return into ourselves", for it is the spirit at the heart of our inmost self that links us to the ultimate unity. In the seventh book of the *Confessions* Augustine tells us how in such an act of introspection he found God—the "Changeless Light," at once immanent and transcendent, which is the source of every intuitive recognition of truth and goodness. This discovery of God was a more than the conclusion of a process of reasoning: it was a mystical experience, a vision or touch that came and went. But it left behind it the answer to Augustine's unsatisfied questionings. God is light, and evil is darkness, as the Manichaeans said. But neither is a material substance; the changeless light of God is pure spiritual being, and evil is non-entity, as darkness is but the absence of light.

Augustine's mystical experience, his awareness of God, had been momentary and fleeting. He believed that this could be only because he had not made for himself the necessary total identification of supreme value with spirit; he was still himself entangled with the flesh. In fact, Neoplatonism had reinforced the Manichaean principle that the way of return to God must be through escape from the body; and for Augustine this meant primarily and immediately escape from the ties of sexuality. The immortal story of his conversion in the eighth book of the *Confessions* tells of his coming to learn of the heroic achievements of Christian asceticism in east and west, of the self-contempt induced in him by the contrast of his own weakness, and of the final breakdown of resistance in the Milan garden, when, at the sound of a child's voice calling "*tolle, lege: tolle, lege*" ("take up and read"), he opened the Pauline Epistles and read the words: "Put on the Lord Jesus Christ, and make no provision for the flesh, to gratify its desires."

This was in the late summer of the year 386. Vacation was near, and Augustine resigned his chair and went with some young pupils and his mother to a reading party at a country house lent by a friend. The time there was spent in literary study and philosophical discussions, out of which came the earliest of Augustine's surviving works—the dialogues on epistemology and ethics, which display so little of the storm and stress of a religious conversion and so little concern with specifically Christian themes that critics have been led to question the accuracy of the *Confessions* story

written many years later. It is true that Augustine's struggle against the domination of his sexual nature can be regarded as the final phase in that fluctuating pursuit of the "philosophic life" in the form in which his reading of the *Hortensius* had first presented it to him. But there is no sufficient reason for doubting that he was a Catholic Christian in intention when he received baptism at the hands of Ambrose in the spring of 387. What is certain is that when three or four years later he wrote his treatise *De vera religione* (*On the True Religion*) he was still thinking of Christianity in Neoplatonic terms. The divine Word (Logos) in Christ is the mind or spirit of Plotinus, illuminating the reason, through whom the human soul has access to the transcendent Godhead. Christ's human life is our example of the ascetic victory over the pains and pleasures of the flesh; Christian morals serve only to purify the soul for the life of contemplation; and Christian faith is the necessary acceptance of the church's authority in this preliminary stage of training.

Bishop and Christian Philosopher.—Shortly after his baptism, Augustine left Milan with his mother and a small party of friends, to return to Africa. At the port of Ostia, on the journey, Monica died; and Augustine has recorded his last talk with her, in which son led mother, through a discourse formed on the pattern of the Neoplatonic "ascent" from this world to the other, to share with him a momentary experience of the life eternal. Home again at Tagaste, the friends formed a little community devoted to the religious life of contemplation and study. But its peace was soon broken when, on a visit to Hippo in 391, Augustine was forced to accept ordination as assistant priest to its old bishop, Valerius. Five years later Valerius died, and Augustine entered the episcopate in which he was to labour until his death. The bishop in Roman Africa was not only the pastor of a parish, the busy teacher and preacher, but the presiding judge in a much-frequented court of summary jurisdiction in civil cases. Augustine never enjoyed robust health, and the vast extent of his literary output was made possible only by the constant services of stenographers and by an extraordinary capacity for the extempore formulation of ordered thought, of which approximately 500 sermons remain as proof. He was not a systematic theologian. Much of his writing was in response to the appeals that his growing reputation in the Christian world brought to him for the solution of the most diverse problems. Over 200 of his letters have been preserved, many of them having the scale of minor treatises. He was tireless in controversy with Manichaeans, Donatists and Pelagians. But his deepest thought, the real Augustinianism, is to be found in his scripture commentaries and homilies, especially his expositions of the Psalms and his tractates on the Gospel and First Epistle of St. John. The characteristic pattern he imposed upon Christian theology was not the outcome of controversy.

The decisive turn was given to his thinking by his ordination to the priesthood, which dragged him against his will from the *vita contemplativa* into the world, and at the same time diverted his studies from philosophy to Scripture. The realities of pastoral experience among the very imperfectly christianized people of an African seaport, together with the rapid impregnation of his mind with the categories of biblical religion, made it impossible for him to overlook the differences between Neoplatonism and Pauline Christianity. The knowledge of God and of the soul always remained what he had declared it to be on the eve of his baptism—the one and only knowledge that he desired; and Plotinus had not been mistaken in bidding him look within himself if he would find God, for the Bible also tells of a likeness to God imprinted on the soul. But while for the Neoplatonist the soul's likeness to God is that of a depotentiated divinity, for the Christian it is that of a temporal and mutable image of the "Eternal and Changeless." Augustine was assured that it is the task of a Christian philosophy, guided by the scriptural revelation, to seek to know God through his image in the soul; and this was the path he followed in his great treatise *De Trinitate* (*On the Trinity*). He insisted that a true knowledge of the soul's nature can be based only on the immediate deliveries of self-consciousness; and the soul's awareness of itself is of a trinity in unity, which reflects "as in a glass darkly" the being of its Maker. My knowledge of my own being, of my own thinking, of my own willing, is not open to doubt; there is an ego, subject of existence, cognition and conation. But in none of these aspects is the ego self-sufficient or independent: it cannot maintain its own being, produce its own knowledge or satisfy its own desires. Augustine believed that he had learned from the Platonists to find in God "the author of all existences, the illuminator of all truth, the bestower of all beatitude." But his cosmology, epistemology and ethics were his own.

This tripartite philosophy may be summarized as follows:

1. Creation in Plotinus is motiveless and purposeless, the automatic by-product of the divine self-contemplation: in Augustine its source is "the will of a good God that good things should be." The outgoing energy of creative love forms the basic principle of his entire theology. Since nothing can come into being or continue in it but by this divine will to create, all that exists is good "in so far as it has being"; and since there are evidently degrees of goodness, we must also hold that there are degrees of being. But even the formless matter that is nearest to "not being" is essentially good because God made it; the origin of evil is not to be sought in material existence. Augustine persistently refused to unload upon the material conditions of human life the responsibility for human wickedness.

2. How is knowledge possible? Following Plato, Augustine argued that the ability to make true judgments never can be inserted into the mind from outside. The human teacher never can do more than help his pupil to see for himself what he already knew without being aware of it. Of these a priori judgments Augustine's favourite examples are the propositions of mathematics and the appreciation of moral values. They cannot be the construction of the individual mind, for all minds agree in accepting their truth when they have been properly formulated. The individual thinker does not make the truth, he finds it; and he is able to do so because Christ, the revealing Word of God, is the *magister interior*, the "inward teacher," who enables us to see the truth for ourselves when we listen to him.

3. Augustine accepts the basic assumption of ancient ethical theory that conduct is properly directed to the achievement of eudaemonia—the happiness or well-being which is taken to be the one universal desire of humanity. Now Augustine's cosmos is an ordered structure in which the degrees of being are at the same time degrees of value. This universal order requires the subordination of what is lower in the scale of being to what is higher: body is to be subject to spirit, and spirit to God. Man must know his place in the order of the universe, and knowing it must voluntarily accept it; that is, he must set upon himself and upon everything else the relative value that is properly due. Augustine's word for the ethical valuation that influences conduct is *amor* ("love"). *Amor* is the moral dynamic that impels us to action. If it is rightly directed we shall never set a higher value on what is lower in the scale. All lesser goods are to be used as means or aids toward the higher; only the highest is to be enjoyed as the ultimate end on which the heart is set. And because the supreme good is also the universal good, the good of all, it can never be attained if what we are seeking is a private good of our own. The selfish pursuit of happiness must defeat its own end. But the supreme good in whose fruition alone we reach our perfection is for Augustine the God whose nature is *agape*, love in the New Testament sense of the word. If then our love, our *amor*, can rise to the enjoyment of God, it will become a participation in the divine *agape*, *caritas*, charity itself. God will have given himself to us, and by sharing in his love we shall love one another as he loves us, drawing from him the power to give ourselves to others.

Donatist Schism.—The energies of Augustine, both pastoral and literary, were for the first 15 years of his episcopate distracted by the wearisome struggle to end the schism in the African church that had persisted for nearly a century. The Donatists (*q.v.*), who in the country districts and in many towns were actually more numerous than the Catholics, claimed to be the only true church on the ground that their ministry was the only one whose succession had not been stained by apostasy in the great persecution of the years 303 to 313. Imperial attempts to suppress the schism had stimulated the martyr spirit that had always marked African

Christianity, and gained Donatism the support of strong elements in the native population whose grievances were social and economic rather than ecclesiastical. The schism maintained itself by fanatical violence, and Augustine's persevering attempts to settle the questions at issue by peaceful discussion were fruitless. In the end, the imperial government became convinced that Donatism was a danger to the security of Africa. The Donatist bishops were compelled to meet their Catholic rivals at a formal conference held under an official arbitrator at Carthage in 411, the foregone conclusion of which was the victory of the Catholic case.

Donatists and Catholics were agreed that the power of the Holy Spirit is conveyed to the believer through the sacraments administered by the church. The Donatists alleged that the sacraments require for their validity a ministry undefiled by mortal sin; for the Spirit departs from the sinner, who cannot therefore "confer what he does not possess." Augustine replied that the sacraments convey the Spirit in virtue of Christ's ordinance alone, and that this validity cannot be affected by the worthiness or unworthiness of the human minister. The Spirit's supreme gift is charity; it is charity that makes the church one body in Christ, and the ultimate cause of schism is the pride that is the denial of charity. Unfortunately Augustine, who had for long stood out against the use of any means but persuasion to bring the schism to an end, eventually was induced to approve the enforcement of legal penalties upon the schismatics in the interest, as he believed, of the many whom fear of Donatist violence had kept from returning to the church. His famous saying "Love, and do what thou wilt" was in fact a defense of compulsion in the service of charity.

Pelagian Heresy.—As the Donatist controversy was ending, Pelagianism was already beginning to threaten doctrines of sin and redemption traditional in the Western Church. Pelagius (*q.v.*) had set himself to resist the slackening of Christian moral standards. Against those who pleaded human frailty in excuse for their failings, he insisted that God has made every man alike free to choose and to perform the good; that it is the essence of sin to be a voluntary act which God's law forbids and which the sinner was free to avoid; and that were not this freedom real, there could be no justice in God's punishments and rewards. Pelagius himself had not desired to challenge Catholic doctrine; but this reduction of Christianity to a bleak moralism could not avoid conflict with the plain implications of the church's sacramental and liturgical practice. Baptism had always been "for the remission of sins"; and infants were held to need it because they inherit the guilt of Adam's transgression, which, as St. Paul taught, brought death upon the whole race of men. The doctrine of original sin was firmly established in the Western Church before Augustine's time; and when it was openly rejected by Pelagius' disciple Coelestius, there was no escape for Pelagianism from being branded as a heresy. The prevarications of Pelagius were able to persuade Pope Zosimus (417–418) to reverse the condemnation pronounced by his predecessor, Innocent I. But in the spring of 418 the African bishops obtained from the emperor Honorius an edict imposing banishment on the heretics; and Zosimus was obliged to come into line.

Augustine had been the soul of the church's resistance. He had seen at once in Pelagianism not merely a denial of the virtue of Christian baptism but a fatal misconception of the relationship between God and man. For to assert that man can achieve righteousness by his own effort is to contradict the fundamental truth that God is the giver of all good. Before the controversy began, Augustine had worked out his own rationalizations of the doctrines of original sin and divine grace—rationalizations in which the church was to prove unwilling to follow him all the way. Accepting the traditional belief in the fact and in the penal consequences of Adam's transgression, he defined the fact as man's refusal to accept his place in the created order, and the consequences as a dislocation of the order of man's own nature—the revolt of flesh against spirit. Accepting the traditional belief that all men are involved both in Adam's guilt and in its punishment, he argued that this involvement takes effect through the dependence of human generation on the sexual passion, in which the impotence of spirit to control flesh is most clearly seen. It was this linking of original sin with human sexuality that exposed Augustine in his old age to the most damaging criticisms of the Pelagian bishop Julian, who boldly asserted the moral neutrality of the instincts that belong to man's created nature, and charged Augustine with relapsing into Manichaeism in his argument that an impulse which we are bound to fight and conquer must therefore be evil. But it is important to distinguish Augustine's profound understanding of the nature of human sinfulness from his disastrous attempt to explain its propagation. The fall of man means (he said) that in all of us the true order of love has been violated. Departing from the love of God above us, we have followed the love of self and become subject to what is below us. Man has fallen by the act of his own will. He cannot by a similar exercise of will reverse the consequences of that fall: the subjection of spirit to flesh is a slavery from which the perverted will has no power to deliver itself, just because it cannot will the deliverance. What is needed is a kind of reversal of gravity—the substitution of an uplifting for a down-dragging love. And it was Augustine's belief that this could happen only by that gracious descent of the divine love to dwell within the sinner, which is the gospel of the Incarnation and of Pentecost.

Pelagius claimed to recognize the grace of God in creation and revelation. All men have been created free to do what is right when they see it, and Christians have received the needed moral enlightenment in Christ's teaching and example. Augustine knew the unreality of the Pelagian conception of freedom as an innate and absolute power of choice, unaffected by circumstances. He pointed to the inescapable conditioning of all moral activity by the situation of the agent—outside whose control are in general not only the presentation of an object but also the kind of feeling that the presentation excites. But the act of will is dependent on feeling as well as on cognition. In Augustine's words: "Men will not do what is right, either because the right is hidden from them or because they find no delight in it. But that what was hidden may become clear, what delighted not may become sweet—this belongs to the grace of God" (*De peccatorum meritis*, ii, 26). Augustine insisted that without this delight in righteousness there can be no true freedom in well-doing, but only a servile obedience to law. The love of God which is the motive of the Christian life must be free. Yet love of God, as St. Paul said, enters our hearts by the gift of the Holy Spirit; and Augustine found it increasingly difficult to leave room in his doctrine of grace for a genuinely free response on man's part to the Spirit's gift. The unexamined assumption that everything in human life must be ascribed either to God's working or to man's compelled him to hold that God alone is the cause of every human movement toward good. In the first year of his episcopate, the study of St. Paul's argument in Rom. ix–xi had convinced him that no event in time can alter the eternal setting of God's will toward any human soul: his elect are chosen "before the foundation of the world." God knows—not before, but apart from, the time process—how each individual in the course of time will respond to the particular form in which grace is offered to him; and the elect alone receive the grace that will win their acceptance.

The rigour of this doctrine did not soften in face of the Pelagian challenge. In *De civitate Dei* (*The City of God*), the magnum opus on which Augustine was working throughout the Pelagian controversy, he drew a picture, as majestic as it is appalling, of the "beginnings, courses and destined ends" of the two invisible societies of the elect and the damned. The work seems to have been in his mind before the capture of Rome by the Visigoths in 410 had shaken the empire; but it took the form of a Christian apologetic against the pagan claim that the disaster was consequence and punishment of Rome's apostasy from its ancestral religion. Augustine's two cities are not to be identified with Christian church and pagan or secular state. They are symbolic embodiments of the two spiritual powers which have contended for allegiance in God's creation ever since the fall of the angels—faith and unbelief, "the love of God proceeding to disregard of self, and the love of self proceeding to disregard of God" (*De civitate.*, xiv, 28). Neither love is embodied in its purity in any earthly institution; in this world the heavenly and earthly cities

are inextricably intermingled. If there is a philosophy of history to be found in the *De civitate Dei*, it is the religious philosophy of predestination.

Augustine in his old age was hard put to it to reassure some of his own disciples, to whom his doctrine seemed to make moral effort futile and praise and blame alike groundless. But he would retract nothing. His last completed treatises drew out the logic of predestination to its most ruthless conclusions. Though his doctrine in its final form was never accepted by the church, it reappeared virtually unmodified in both Aquinas and Calvin, the most acute thinkers of scholasticism and reform. It may indeed be regarded as product of the too audacious attempt of the time-bound human mind to contemplate existence with the eye of the eternal God.

Influence.—The end of Roman civilization in Africa was near, and the Vandal armies were besieging Hippo, when Augustine died there on Aug. 28, 430. Not many years later, Vincent of Lérins defined Catholic orthodoxy in the famous phrase *quod ubique quod semper quod ab omnibus creditum est* ("What is everywhere, what is always, what is by all people believed"). He dared not call Augustine a heretic in so many words, but it was against the extravagances which he rightly detected in Augustinian doctrine that his definition was aimed. That these extravagances have been a legacy to theology the more noxious because of the weight of authority attached to their author, cannot be denied. But that should not prevent our grateful acknowledgment of the debt which Christian thinking, through the centuries, has owed to the influence that Augustine has continued to exercise upon it, and that has spanned and may one day reconcile the divisions of western Christendom. The secret of that influence is to be found not so much in the brilliance and profundity of his intellect, the magic of his style or the validity of his constructions as in the unique power of his religious genius. St. Anselm of Canterbury and St. Bernard of Clairvaux, the makers of the English Prayer Book and St. Francis of Sales, Pascal, Bossuet and Joseph Butler, Jacques Maritain, Reinhold Niebuhr and Paul Tillich—all these have in their different ways drawn inspiration from one in whom they have been compelled to recognize "the heart of the matter." *Verus philosophus est amator Dei* ("The true philosopher is the lover of God"). In those words from the *De civitate* (viii, 1), Augustine has left us at once the best portrait of himself and the fullest justification of his life's work. St. Augustine has been revered as a doctor of the church since the early middle ages. His feast is celebrated on Aug. 28. *See* also references under "Augustine, Saint," in the Index.

Bibliography.—For editions of separate works of St. Augustine *see* *Clavis patrum Latinorum*, ed. by E. Dekkers, *Sacris erudiri*, vol. iii (1951); the critical edition in the Vienna *Corpus scriptorum ecclesiasticorum Latinorum* (1866–) is not complete, and for works not included in it *see* the complete works in J. P. Migne, *Patrologia Latina*, vol. xxxii–xlvii (1845–49). Modern English translations of selected works are available in the two series "Ancient Christian Writers," ed by J Quasten and J. C. Plumpe (1946–), and "Library of Christian Classics," ed. by J. Baillie *et al*. (1953–).

AUGUSTINE OF HIPPO, RULE OF ST. Of the four rules that at one time or another have been attributed to Augustine, the one known as *Regula Consensoria* is certainly not by Augustine, but of Spanish origin. This leaves three rules that may claim Augustinian authorship. (1) The *Disciplina Monasterii* (*DM*). Except for two sentences serving as introduction and conclusion respectively, *DM* is a terse document of about 350 words, giving to a religious community of men prescriptions for choral prayer, reading and manual labour, observance of monastic poverty, obedience and silence, conduct outside the monastery and maintenance of discipline. (2) The *Regula ad servos Dei* (*RA*), containing the fundamental norms of monastic community life, with emphasis on charity as the foundation of perfection. (3) The female version of *RA* (*EA*), which in many manuscripts and printed editions is combined with Augustine's *Letter* 211 addressed to nuns.

Until about 1940 the most general assumption had been that *EA* was the only rule written by Augustine, while *RA* was explained as a later adaptation from *EA* and, like *DM*, thought to be of unknown authorship. This traditional view was challenged by investigations that threw new light on the text history of the three documents. In almost all the manuscripts from the 6th to the 12th century *DM* and *RA* are found together, constituting, par excellence, the *Rule of St. Augustine*. In this combination they were known to Benedict of Nursia, Caesarius of Arles and others. The two texts were disjoined in the early 12th century when *DM*, some of its main tenets being no longer applicable, was eliminated except for the introductory sentence, which continued its function as preface of the "truncated" *Rule of St. Augustine*.

These findings have produced, roughly speaking, three new theories: the first ascribing to Augustine all three rules, the second limiting his authorship to *DM* and *RA*, the third crediting him with the composition of *RA* only. Though none of these theories is based on incontrovertible evidence, research has clearly established that the combined text of *DM* and *RA*, known as the *Rule of St. Augustine* throughout the middle ages, was an extremely influential document whose existence can be traced back to almost the time of Augustine.

See J. C. Dickinson, *The Origin of the Austin Canons and Their Introduction Into England*, appendices i and ii (1950); G. B. Ladner, *The Idea of Reform: Its Impact on Christian Thought and Action in the Age of the Fathers*, pp. 356 ff., with references given there (1959). (Ru. E. A.)

AUGUSTINIAN CANONS (Austin Canons; also called Canons Regular of St. Augustine), a religious order in the Roman Catholic Church, which rose in close connection with the great reform movement known as the Gregorian Reform. Its main characteristic was the union of clerical status and a full common life. Though the ideal of clerical community life, as it had been understood by its first ardent promoters, Eusebius of Vercelli (d. 370 or 371) and Augustine of Hippo (354–430) (*qq.v.*), had partially and sporadically been revived by later ecclesiastical lawgivers (*e.g.*, Chrodegang of Metz; d. 766), it came to full fruition only during the 11th and 12th centuries. The moral impulse emanating from the Roman synods of 1059 and 1063 and the Gregorian Reform led the canons of many cathedral and collegiate chapters to give up private ownership and to live together according to monastic ideals (*see* Cathedral). Where an entire chapter was unwilling to join the reform, often a few of its canons established a new collegiate chapter. The adoption of the rule of St. Augustine made slow progress at the beginning, but had become almost universal by 1150 (*see* Augustine of Hippo, Rule of St.). Owing to the efforts of bishops who were supporters of the Gregorian Reform, and to the generosity of secular patrons, the order experienced a vigorous growth in Italy, France, England and the empire (especially in Austria, Bavaria and the future Switzerland). By 1215 there were 173 independent houses in England alone. The 14th and 15th centuries saw a second flowering of the order through the rise of reform congregations (Congregation of Windesheim, Lateran and Renan congregations, Congregation of St. George in Alga at Venice).

Many houses of the Augustinian Canons perished in the times of the Protestant Reformation. The French Revolution and later

secularizations put an end to the existence of a great many others. At mid-20th century there were four congregations: Lateran Congregation, divided into five provinces (Italian, French-Belgian-Dutch, English, Spanish-American, Polish), with nearly 500 members; Austrian Congregation with fewer than 300 members; Congregation of Mount Joux (Great St. Bernard) with fewer than 100 members; Congregation of St. Maurice of Agaunum (Switzerland) with about 140 members.

(RU. E. A.)

AUGUSTINIAN HERMITS (AUSTIN FRIARS; ORDER OF THE HERMIT FRIARS OF ST. AUGUSTINE), one of the four great mendicant orders of the middle ages, owing its origin to the centralizing policy of the popes of the 13th century. In 1256 Pope Alexander IV reorganized several congregations of hermits with houses in central and northern Italy into one active order under the rule of St. Augustine (*see* AUGUSTINE OF HIPPO, RULE OF ST.), calling them from their eremitcal seclusion to the lay apostolate in the cities. Though this transfer made the term hermit a misnomer, the official name of the order retained it, since it served to distinguish the Austin Friars, as they were called in England, from the Austin Canons.

Besides following the rule of St. Augustine, the Augustinian Hermits are subject to special constitutions. The order, numbering both priests and lay brothers among its members, is divided into provinces. At the head of the order is the prior general, who is aided by a council (*curia*). Each province is governed by a provincial with his counselors (definitors), and each monastery by a prior. The provincial, priors and definitors are elected every three years by the provincial chapter, the prior general and his *curia* every six years by the general chapter. The legislative power resides in the general chapter. The dress of the order is a black habit with a long pointed cowl and a black leather cincture.

After the Great Union of 1256 the order rapidly spread not only in Italy but also in England, France, Spain and the countries north of the Alps. Its main duty was the care of souls. Learned Augustinian Friars also took a prominent part in university life, in the councils of the church and in practical affairs of ecclesiastical policy. The great geographical discoveries at the beginning of the modern age brought Augustinian missionaries to Mexico, South America and the far east. The most prosperous period of the order was the 14th century. Then gradually signs of decay appeared. Attempts to counteract the decline of monastic discipline led to the organization of several reform congregations. The Reformation, later revolutions and secularization brought about the total or partial disappearance of many Augustinian provinces. In the 20th century the order experienced a revival, especially in Belgium, Germany, the Netherlands, Ireland, Spain and the United States, and in the early 1960s it numbered about 4,000 members. In addition to its apostolic ministry, including foreign missions, the order is dedicated to the advancement of learning by teaching and scholarly research.

The second order, which is the female branch, after the Reformation shared the same fate as the male. There exist about 130 convents of Augustinian nuns. All but three (Cascia and Aquila in Italy, Maarssen in the Netherlands) have passed from the jurisdiction of the prior general to that of the diocesan bishop.

See R. Arbesmann and W. Hümpfner (eds.), *Jordani de Saxonia Liber Vitasfratrum* (1943); *Augustiniana* 6 (1956); and the articles "Augustiner-Eremiten" and "Augustinerinnen," in *Lexikon für Theologie und Kirche*, 2nd ed., vol. 1 (1957), with references given there.
(RU. E. A.)

AUGUSTINIANS, in the Roman Catholic Church, a generic name applied sometimes to the entire group of religious orders and congregations of men and women whose constitutions are based on the Augustinian rule (*see* AUGUSTINE OF HIPPO, RULE OF ST.); *e.g.*, Dominicans, Premonstratensians, Servites, Trinitarians, Ursulines (*qq.v.*), Gilbertines (*see* GILBERT, SAINT), etc. More commonly, however, the name is used to designate two main branches of Augustinians, namely, the Augustinian Canons and the Augustinian Hermits (*qq.v.*), with their feminine offshoots. *See* also MONASTICISM. (RU. E. A.)

AUGUSTUS, the honorific cognomen or additional name first given by decree of the senate in 27 B.C. to the Roman emperor generally so called (life span 63 B.C.–A.D. 14), who in 44 B.C. had changed his original name, GAIUS OCTAVIUS, to GAIUS JULIUS CAESAR (that of his adoptive father), but who for the period 44–27 B.C. is conventionally known in English as OCTAVIAN, though he himself never used the name Octavianus. The cognomen Augustus (Gr. *Sebastos*) was borne in fact by all the succeeding Roman emperors, but is not used by historians to designate them specifically.

Octavius was born in Rome on Sept. 23, 63 B.C., of a wealthy and respectable but obscure family of Velitrae in Latium. His father, Gaius Octavius (d. 58 B.C.), was its first member to become a senator, being praetor in 61 B.C. and governing Macedonia with distinction. His mother, Atia, was the daughter of Julia, the great Julius Caesar's sister, and this connection determined his career. Caesar regarded the younger Octavius as the most promising of his male relatives; he gave him a military decoration at his African triumph, took him with him on his Spanish campaign in 45 B.C., made him a patrician and had him elected a pontifex. Finally in his will Caesar appointed Octavius heir to three-quarters of his estate, in default of a son of his body, and adopted him as his son.

Rise to Power.—When Caesar was murdered in 44 B.C., Octavius was pursuing his studies at Apollonia in Illyria. He crossed to Italy and, learning that he was Caesar's heir and son, determined to take up the dangerous inheritance. His position was very weak. He was an obscure youth of 18, lacking experience and influential connections. He was naturally suspect to the anti-Caesarian party, and he was rebuffed by Mark Antony (*see* ANTONIUS) who was generally accepted as the leader of the Caesarian party and had taken possession of Caesar's money and papers. His only asset was the fact that Caesar had adopted him, and he promptly assumed Caesar's name, paid Caesar's legacies to the people out of his own pocket and celebrated the *ludi Victoriae Caesaris* (games in honour of Caesar's victory) at his own expense. At the same time Octavian ingratiated himself with Cicero, who persuaded himself that he could use the youth as a tool against Antony and then discard him. On Antony's break with the senate Octavian illegally raised a force of 3,000 men from his adoptive father's army veterans and seduced two of Antony's legions from him. When the senate resolved on war with Antony, it regularized Octavian's position on Cicero's proposal, making him a senator, granting him *imperium pro praetore* (*see* PRAETOR) and instructing him to assist the two consuls of the year 43 in the war. Antony was defeated at Mutina (Modena), but both consuls were killed, and Octavian thus found himself in command of the whole victorious army. He promptly demanded the consulship and, when the senate demurred, marched on Rome. He was elected on Aug. 19 43 with his uncle Quintus Pedius, and fulfilled his first duty to his adoptive father by a law proscribing his assassins. He could now negotiate on equal terms with Antony, who had joined forces with Marcus Aemilius Lepidus, the governor of Gaul. The three met at Bononia (Bologna) and agreed to share the supreme power. By the *lex Titia* of Nov. 27, 43, they were created triumvirs (*see* TRESVIRI) with absolute authority until Dec. 31, 38.

To cow opposition and raise funds the triumvirs proscribed 300 senators and 2,000 equites. Antony and Octavian then crossed to Macedonia to crush Marcus Junius Brutus and Gaius Cassius (*qq.v.*). After the victory of Philippi (42 B.C.) Antony took charge of the east, while Octavian returned to Italy, where by ruthless confiscations he provided allotments for the veterans. In 41 B.C. he had to fight the War of Perusia (Perugia) to crush a rebellion raised by Lucius Antonius, Antony's brother, who was abetted by Antony's wife Fulvia. Antony took Octavian's action amiss, but an agreement was patched up at Brundisium (Brindisi) in the year 40, whereby Antony took all the eastern and Octavian all the western provinces except Africa, which was left to Lepidus; to seal the agreement Antony married Octavian's sister Octavia (Fulvia having died). Next year a pact was signed at

Misenum, on the Bay of Naples, with Sextus Pompeius, in which the triumvirs recognized his rule in Sicily, Sardinia and Corsica, and Antony returned to the east. Sextus soon denounced the pact of Misenum, and friction again arose between Octavian and Antony. A reconciliation was effected however by Octavia at Tarentum (Taranto) in 37.

The triumvirate, which had already legally expired, was prolonged for another five years, and the triumvirs agreed to make common cause against Sextus Pompeius. In 36 Octavian and Lepidus launched a joint attack on Sicily; Octavian himself was badly defeated, but his trusty supporter and best general, Marcus Vipsanius Agrippa (*q.v.*), saved the situation, and Sextus was defeated. Lepidus, who quarreled with his colleague after the victory, was deserted by his troops and deposed. Octavian, who had since 38 B.C. adopted as a *praenomen* or forename the word *imperator*—originally used to designate a magistrate vested with military command—and styled himself *Imperator Caesar divi filius* ("son of the god"; *i.e.*, the deified Julius), returned to Rome to celebrate an *ovatio* or minor triumph and among other honours received the sacrosanctity of a tribune (*q.v.*) of the plebs.

Octavian was now master of all the west, as Antony was of all the east, and it was clear that a struggle for supreme power must come. Octavian gained prestige and popularity from his victory over Sextus, which secured the grain supply of Rome, and during the next few years he and his supporters, notably Agrippa, spent generously on public works, while he himself occupied his troops and won more glory by the conquest of Illyricum (Dalmatia) in 35–33 B.C. Meanwhile Antony lost prestige by his unsuccessful Parthian campaigns and alienated Italian feeling by his entanglement with Cleopatra. Octavian thus was able to build himself up as the champion of Italy and Rome against the oriental queen and her degenerate paramour.

The crisis came in 32 when the second five-year period of the triumvirate expired, and Octavian summoned Antony to lay down his powers. Both the consuls and over 300 senators withdrew from Italy and joined Antony, but Octavian forced the vestal virgins to surrender Antony's will and read it to the rump of the senate. It was a most indiscreet document, favouring Cleopatra and Antony's children by her, and exacerbated public feeling against Antony. Octavian was able to organize a "spontaneous" oath of all Italians, whereby they swore personal devotion to himself and demanded that he be their leader in the forthcoming war. All the western provinces followed suit. War was solemnly declared on Cleopatra, and in 31 B.C. Octavian, having regularized his position by assuming the consulship (he was technically a private citizen during 32), assumed command. At the battle of Actium (*q.v.*) on Sept. 2, 31, he decisively defeated the combined forces of Antony and Cleopatra, who fled to Egypt. On Aug. 1, 30, he entered Alexandria; Antony and Cleopatra both committed suicide, Egypt was annexed and a vast treasure captured. Next year Octavian returned to Rome, where he celebrated a magnificent triple triumph for the conquest of Illyricum, the victory of Actium and the capture of Egypt.

Augustan Constitution.—Octavian was now undisputed master of the empire, but his constitutional position was nebulous. From 31 onward he was elected consul year after year, but over and above his constitutional authority as consul, he claimed undefined supreme powers in virtue of the Italian oath of 32 B.C. Now that the war was over he would alienate the republican-minded upper and middle classes of Italy if he continued to exercise such monarchical power. In 28 B.C. he began by abolishing the illegal acts of the triumvirate and, with his fellow consul Agrippa, conducted a census and a drastic purge of the senate, which had swelled inordinately in numbers and contained many unworthy members. Then on Jan. 13, 27, he solemnly resigned his extraordinary powers, remaining merely one of the two consuls of the year. The senate in gratitude conferred upon him the cognomen Augustus on Jan. 16, 27, but begged him not to desert the republic, and he agreed to undertake the pacification of the more unruly provinces. For this purpose he was assigned for ten years a very large province, comprising Spain (except Baetica, the southern part), Gaul, Syria and Egypt, and granted authority to declare war and make treaties. With this exception, which was a temporary measure and had precedents in the extraordinary commands voted to Pompey and Caesar and others in the late republic, the normal republican constitutional machinery was restored. Free elections were resumed, the magistrates, under the guidance of the senate, performed their normal functions, and annual proconsuls governed the ten provinces not assigned to Augustus.* The coins proclaimed Augustus *libertatis populi Romani vindex* ("defender of the Roman people's freedom"), but he retained control of all the legions except a few commanded by the proconsuls of Illyricum, Macedonia and Africa.

Augustus spent the next three years (27–25) in the western part of his own province, where he finally subdued the turbulent tribes of northwestern Spain, the Astures and Cantabri. Every year, however, he stood for the consulship and naturally was elected to it. Such a continuous tenure of the consulship had probably not been envisaged in the settlement of 27 B.C., and it caused mounting discontent. Not only were the nobility aggrieved that their chances of attaining the consulship were halved, but also it was widely felt that it was contrary to the law and spirit of the republic that one man should hold one of the supreme magistracies continuously. Discontent came to a climax in 23 with a conspiracy to assassinate Augustus led by Aulus Terentius Varro Murena, his colleague in the consulship and hitherto a loyal supporter. Augustus saw that if he was to avoid Julius Caesar's fate he must make drastic concessions, and on July 1, 23, he resigned the consulship, never to hold it again save twice (5 and 2 B.C.). He still retained his province (his tenure of which would not expire until 17 B.C.) as proconsul, but to show that he would hold it no longer than necessary, he surrendered the pacified provinces of Gallia Narbonensis (southern Gaul) and Cyprus. In compensation for the loss of the consulship he received certain privileges. It was decreed that he should not, like other proconsuls, forfeit his *imperium* (chief authority) by entering Rome and that he should have *majus imperium* or authority superior to that of other proconsuls, so that he could if need be override their decisions. He was also given special powers to convoke the senate and to introduce business in it. Finally he was granted the powers of a tribune of the plebs (*tribunicia potestas*) for life. The significance of this grant is somewhat obscure. It gave him certain rights, those of introducing legislation and vetoing the acts of all magistrates, which he in fact used very rarely but which might be useful in an emergency. It was probably primarily a propaganda move, designed to enlist the support of the common people, who still regarded the tribunes as their protectors and champions.

In 22 Augustus set out on a prolonged tour of the eastern provinces, from which he did not return to Rome until 19 B.C. If the republican opposition was satisfied by the new arrangements, the people were not. They offered Augustus a dictatorship, an annual and perpetual consulship and other extravagant offices, and in 22 and 20 insisted on electing him to the consulship, though he refused to stand. It would appear that the mass of the people really was afraid that Augustus would withdraw permanently to his province and leave the senate to govern. Alarmed by riots that it was unable to control, the senate pressed Augustus to intervene and celebrated his return with an altar to Fortuna Redux (Fortune that brings back). The republicans were now prepared to make concessions. In 19 B.C., according to Dio Cassius, the consular *imperium* was conferred upon Augustus for life. The accuracy of this statement has been doubted, but henceforth Augustus undoubtedly exercised executive powers in Rome and Italy like a consul. His constitutional position was now complete and no further changes were made in it. He was elected pontifex maximus (*see* PONTIFEX) with acclamation in 12 B.C. on the death of Lepidus, who had previously held the office, and in 2 B.C. he was saluted *pater patriae* ("father of his country"), but these were mere honours. The tenure of his province was renewed at intervals of five or ten years until his death in A.D. 14.

It has been much debated whether Augustus ever really intended to restore the republic, or wished to set up a system of

dual control, a "dyarchy" in which he and the senate should share the government of the empire, or whether he merely established the façade of a republic to satisfy upper-class sentiment. Some of his utterances suggest that at first he may have hoped that, having set the empire in order, he would be able to retire and leave the senate to carry on; but such hopes, if he ever entertained them, soon faded. He certainly endeavoured to stimulate the magistrates and senate into taking a more active part in the government and promoted reforms in the republican administrative system. Certain functions, for instance, previously neglected by the aediles were transferred to newly created boards of senatorial commissioners such as the *curatores aquarum* ("keepers of the water supply"); it was only as a last resort, after many experiments, that Augustus personally took over two of their functions, the fire brigade and the grain supply of Rome (*see* AEDILE). At the same time he interfered as little as possible in the running of the constitution. He appears to have left the elections free, only commending to the people a few candidates whom he favoured, but by the end of his life this *commendatio* had hardened into a right to nominate a limited number of candidates whose election was uncontested. He likewise tried hard to get the senate to revise its own roll of membership, and though he had to carry out the task himself on two occasions (18 and 11 B.C.), he eventually succeeded in his aim in A.D. 4. But he kept the real power firmly in his hands. Above all he never relaxed his hold on the army.

After 19 B.C. Augustus possessed constitutional prerogatives that enabled him to enforce his will in almost any contingency. Outside his own province, however, he preferred to use them as little as possible and to govern through his moral authority (*auctoritas*). Thus while he himself introduced certain laws in virtue of his *tribunicia potestas*, most of the legislation of the latter part of his reign was moved by the consuls though inspired by him. The consuls also conducted most business in the senate, though it was prepared by a small committee over which Augustus presided. Despite his *majus imperium* he gave more advice than commands to proconsuls. In his official titles he ignored his *imperium* and stressed his *tribunicia potestas*. He preferred to be known as the *princeps*, the senior statesman of the republic.

Perhaps the most significant evidence that he never seriously contemplated the restoration of the republic is the care that he took throughout his reign to provide himself with a potential successor. He has been much criticized for assigning this role almost exclusively to members of his own family, but though he may have been partly swayed by personal feelings there were strong political reasons for such a choice. The loyalty of the legions was to the Caesarian family, as Augustus' early career had demonstrated, and the stability of the regime was largely dependent on holding their loyalty. Augustus was unfortunate in begetting no sons. His first marriage—with Scribonia in 40 B.C. —produced only a daughter, Julia, born in 39 B.C. In 38 B.C. he divorced Scribonia and married Livia Drusilla, with whom he had fallen passionately in love, forcing her husband Tiberius Claudius Nero to divorce her. The marriage proved a very happy and lasting one (Livia outlived him), but produced no children. Augustus' only near male relative was Marcus Claudius Marcellus (*see* MARCELLUS), the son of his sister Octavia. Livia had two sons by her first marriage, the future emperor Tiberius and Nero Claudius Drusus (*qq.v.*) who were brought up in Augustus' house.

Augustus' first choice was Marcellus, to whom he married Julia and gave signal preferment. This apparently caused friction with his trusty supporter Agrippa, who in 23 B.C. was placated and removed from the scene by being made Augustus' colleague for five years in his proconsular command and assigned the east as his sphere. Marcellus died the next year, and Julia was promptly married to Agrippa. The marriage produced two sons, whom Augustus adopted as his own, Gaius (born in 20) and Lucius Caesar (born in 17). In 18 B.C. Agrippa's proconsular powers were extended for five years concurrently with Augustus', and he was also made a colleague in his tribunician power for the same period. The plan evidently was that if Augustus died prematurely (his health was always bad), Agrippa would be left in command and would in due course be succeeded by his sons, who were by blood and adoption Caesars. Agrippa's powers were renewed for another five years in 13 B.C., but he died the next year. Augustus then assigned Agrippa's role to Livia's elder son, Tiberius, to whom he married Julia, forcing him to divorce the wife whom he deeply loved. Tiberius was granted the tribunician power for five years in 6 B.C., but almost immediately withdrew to Rhodes and refused to take any part in the government. The reason for the quarrel became apparent when the following year Agrippa's son Gaius Caesar, who was now 15, was elected consul, to assume office five years later, and was acclaimed by the *equites* as *princeps juventutis* ("head of the younger generation"); in 2 B.C. Lucius Caesar was accorded the same honours. Tiberius, who had done sterling service in Pannonia and Germany as Augustus' legate, had no mind to play second fiddle to two boys. Augustus persisted in his policy, assigning a proconsular command to Gaius Caesar in 1 B.C. and entrusting him with the settlement of the Parthian and Armenian problems, but once again he was disappointed in his hopes. Lucius died in A.D. 2 and Gaius in A.D. 4. Augustus was forced to fall back on Tiberius, whom he adopted as his son and associated with himself in the proconsular and tribunician powers for ten years. These powers were renewed and enlarged in A.D. 14, shortly before Augustus' death.

Expansion of the Empire.—Though he was himself no great general, Augustus greatly extended the empire by a long series of wars, some of which he conducted in person but most of which were fought by Agrippa, Tiberius, Drusus and other competent generals. Augustus was not attracted by the lure of eastern conquests and resisted the pressure of public opinion for a war of vengeance on Parthia. In 20 B.C., by a judicious display of force, he induced the Parthian king to surrender the standards and the prisoners captured from Crassus at Carrhae in 53 and to accept a Roman nominee on the throne of Armenia. Having thus restored Roman prestige and satisfied Roman pride he took no further action until A.D. 4, when Gaius Caesar by another show of force again induced the Parthians to acquiesce while he installed a king in Armenia. Augustus confirmed most of the client kings whom Antony had appointed in the east, notably Polemo of Pontus, Amyntas of Galatia, Archelaus of Cappadocia and Herod of Judaea. Galatia however was annexed and added to Augustus' provinces when Amyntas was killed in 25 B.C. An ill-considered attempt to annex Arabia Felix (Yemen) in 26 B.C. proved a dismal failure.

In Europe, apart from the pacification of Spain (26–25 B.C.), Augustus' efforts were mainly directed toward establishing a satisfactory northern frontier; the northern approaches to Italy were still very vulnerable. The first stage was the conquest of the Alps and of Raetia and Noricum up to the Danube, conducted by Tiberius and Drusus (16–14 B.C.). In the next five years (13–9 B.C.) Agrippa, succeeded by Tiberius, subdued Pannonia Illyricum was during this period transferred to Augustus' province Meanwhile Drusus pushed forward east of the Rhine into Germany, reaching the Elbe. On his death in 9 B.C. Drusus was succeeded by Tiberius in this task. For the years of Tiberius' retirement (6 B.C.–A.D. 4) the record is very scanty, but campaigning in Germany went on, and Moesia also seems to have been conquered. When Tiberius returned, a grand strategic plan was formed for the conquest of the Marcomannic kingdom of Bohemia and the establishment of a shorter frontier running up the Elbe to the great bend of the Danube. A converging attack on Maroboduus, king of the Marcomanni, had already been launched in A.D. 6 when the Pannonians broke into revolt. The suppression of the rebellion took three years and strained the resources of the empire severely. It was scarcely complete when Arminius (*q.v.*), king of the Cherusci, trapped P. Quinctilius Varus, the Roman commander in Germany, with three legions and annihilated them in the battle of the Teutoburg Forest (A.D. 9). Discouraged by these successive blows, Augustus abandoned his ambitious plans; Maroboduus remained unconquered, and the legions were withdrawn behind the Rhine. Despite this failure Augustus' achievement was great. He had advanced the northern

frontier to the Danube and added four provinces—Raetia, Noricum, Pannonia and Moesia—to the empire. Incidentally, since these provinces with Illyricum were all added to his sphere, his preponderance in the government of the empire was greatly increased, and since the troops were withdrawn from Macedonia, only one legion was left that was not under his command, that under the proconsul of Africa.

Army.—Augustus at length established the standing army that the empire had long required. After Actium he discharged the greater part of the huge armies he and Antony had collected. He seems to have contented himself with 28 legions (reduced after the Varian disaster to 25), which were maintained as permanent establishments and many of which survived for centuries. From 30 B.C. he signed on recruits for a definite term of years, fixed at 16 originally and at 20 in A.D. 6. The major financial problem, which the senate had never faced under the republic, was the provision of land or bounties for army veterans on discharge. From 30 B.C. to A.D. 6 Augustus bought the land required or paid the bounties out of his own pocket. In the latter year he established a special military treasury for this purpose and despite much opposition from the senate instituted new taxes on Roman citizens to feed it. The auxiliary units that the provincials previously had provided from time to time also were reorganized on a permanent basis, and two standing fleets were established at Ravenna and Misenum. Another military innovation was the transformation of the traditional bodyguard (*cohors praetoria*) of a proconsul into a large standing force of nine cohorts (9,000 men) stationed around Rome. Closely associated with these were the three urban cohorts in Rome itself.

Civil Administration.—To assist him in his multifarious tasks Augustus built up piecemeal a rather rudimentary and uncoordinated administrative machine. He appointed senators of consular or praetorian standing as his delegates (*legati Augusti*) to govern most of his provinces and to command his legions (except those in Egypt). He also appointed a senior senator of consular rank as prefect of the city to maintain order in Rome with the urban cohorts; originally a temporary appointment made when Augustus was absent in Spain in 26 B.C. and repeated for the duration of a visit that he made to Gaul in 16–13 B.C., this office became permanent toward the end of his reign. To command the auxiliary units and govern small provinces he used prefects of equestrian rank; the key province of Egypt, which it would have been dangerous to entrust to a senator, also, by exception, was governed by an equestrian prefect. He also employed *equites* to command the newly organized fire brigade and to manage the grain supply of Rome and to command the praetorian guard. He developed his private household of slaves and freedmen into a central secretariat and financial office. To look after his financial interests in the provinces he used private agents (*procuratores*), who not only managed his private estates but also, in his own provinces, collected the revenues and paid the troops; the principal *procuratores* were usually men of equestrian rank, but some of them, and all the subordinate staff, were Augustus' freedmen or slaves.

The provinces profited greatly by Augustus' rule. First and foremost, they enjoyed peace from the civil wars and their accompanying exactions. Second, Augustus abolished the tithe system wherever it prevailed and with it the extortions of the *publicani* (farmers of the revenues), substituting a fixed tribute based on a census of population and property and collected by the cities themselves. He appointed men of a better type as governors in his own part of the empire and controlled them closely. He sometimes also intervened in virtue of his *majus imperium* to correct abuses in the other provinces and simplified the procedure whereby the provincials could claim redress from extortionate governors.

Social and Religious Policy.—Augustus tried to inaugurate a religious, moral and social reform of the Roman people. He rebuilt derelict temples, restored neglected ceremonies and priesthoods and, in general, attempted to revivify the old state religion with its patriotic associations. In the moral sphere he tried to restore the sanctity of marriage and to stimulate the birth rate by two laws, both passed about 18 B.C., the *lex Julia de adulteriis*, which made adultery a crime, and the *lex Julia de maritandis ordinibus*, which penalized the unmarried and the childless and rewarded parents of large families (the latter law was modified in A.D. 9 by a *lex Papia Poppaea*). In 17 B.C. the advent of a new and better age was inaugurated by the celebration of the Secular games. Later in his reign, by the *lex Fufia Caninia* of 2 B.C. and the *lex Aelia Sentia* of A.D. 4, Augustus regulated and limited the manumission of slaves, seeking to check the excessive adulteration of the citizen body by freedmen.

There was one religious movement that Augustus regulated with great caution. Few things had made Caesar more unpopular than his acceptance of divine honours from Roman citizens. Augustus insisted on his adoptive father's deification and built him a magnificent temple, but as far as he could he allowed no worship of himself by Romans. Even in the provinces he was cautious. The eastern provinces had long been accustomed to worshiping their proconsuls, but he allowed them to build temples only "to Rome and Augustus." He seems however to have come to appreciate the value of this cult as an expression of loyalty to the empire and deliberately introduced it into the more barbarous and recently conquered provinces of the west, inaugurating an altar at Lugdunum (Lyons) in 12 B.C., where the communities of Gaul met to worship Rome and Augustus, and later setting up a similar altar for the Germans at the *oppidum Ubiorum* (Cologne).

Literature and the Arts.—The Augustan age of literature and art is justly celebrated, and Augustus himself did something to stimulate the movement. He was a great builder, who could justly boast that he had found Rome a city of brick and left it a city of marble, and his temples, forums and other public buildings provided commissions for many architects and sculptors. He and his lifelong friend Gaius Maecenas were patrons of the poets and encouraged them to devote their talents to propagating the ideals of the new age. Virgil celebrated the divine origins of Rome (and its present ruler), Horace preached religious and moral reform, and even Ovid popularized the religious revival in his *Fasti*.

Personality and Achievement.—Augustus' character is something of an enigma. During his climb to power he was undoubtedly often unscrupulous and brutal, and his dominating passion seems to have been ambition for power. Having achieved power he mellowed and developed truly statesmanlike qualities. He certainly lived down his youthful excesses and died universally respected and beloved. He was not a genius like his adoptive father Julius Caesar, by comparison to whom he has often suffered, but he possessed political and administrative gifts of a high order. His administrative reforms, in particular the reorganization of the army, were soundly and boldly conceived and stood the test of time. But above all he showed superb tact and skill in gauging and manipulating public opinion. He managed to reconcile all classes, even, it would seem, what remained of the nobility, and succeeded in satisfying the republican sentiment of the educated classes and in rallying it in support of the new regime. It is a testimony to the soundness of his work that the system he established endured with no essential change for three centuries.

Augustus died at Nola in Campania on Aug. 19, A.D. 14.

BIBLIOGRAPHY.—A basic document is the *Monumentum Ancyranum* (*q.v.*), the obituary Augustus composed for himself. There is a brief sketch of his career by Velleius Paterculus, who was a young man at the end of his reign, and a full and detailed narrative, based on good sources, by Dio Cassius (books 45–56). Suetonius' *Life of Augustus* contains much interesting information, particularly of a personal character. The life and times of Augustus are very fully treated in the *Cambridge Ancient History*, vol. x, ch. i–xviii (1934), where full bibliographies are given. The most notable later work is R. Syme, *The Roman Revolution* (1939). *See* also for the constitution and administration, A. H. M. Jones, *Studies in Roman Government and Law* (1960). (A. H. M. J.)

AUGUSTUS II THE STRONG (1670–1733), king of Poland who was also elector of Saxony as FREDERICK AUGUSTUS I, was born in Dresden on May 12, 1670, the second son of John George III, elector of Saxony. He became elector of Saxony on the death of his brother John George IV in 1694. In 1695 and 1696 he led the Holy Roman emperor's troops against the Turks. When John III

Sobieski died in 1696, Augustus was a candidate for the Polish crown and, to further his chances, became a Roman Catholic—a step that was strongly resented in Saxony. He secured his election and coronation on Sept. 15, 1697, and his principal rival, the prince de Conti (François Louis de Bourbon), abandoned the contest.

Augustus continued the war against the Turks, which ended with the treaty of Karlovci in 1699. In the same year he made an alliance with Russia and Denmark against Charles XII of Sweden in order to conquer Livonia, not for Poland but for his own house. The Poles refused to assist this project. Augustus led his Saxons into Livonia in 1700, but was defeated by Charles at Kliszow (near Pinczow) in Poland in July 1702. Deposed in Poland on July 13, 1704, he fled to Saxony. Charles invaded Saxony in 1706 and compelled the elector to sign the treaty of Altranstädt (Sept. 1706), whereby Augustus recognized Stanislaw Leszczynski as his successor in Poland and abandoned the Russian alliance. During the War of the Spanish Succession, Augustus fought for the emperor in the Netherlands but, after the defeat of Charles XII at Poltava in July 1709, he turned his attention to the recovery of Poland and declared the treaty of Altranstädt void. Because of Peter the Great's support, he recovered the Polish crown on Oct. 20, 1709, but the Polish nobles, fearing his absolutist plans, formed the confederation of Tarnogrod against him in 1715. Peter, however, mediated between him and the confederation. The "pacification diet" of Feb. 1717, under Russian protection, limited the Polish army to 24,000 men.

From 1719 Augustus tried to free himself from Russian influence. He entered into various futile diplomatic combinations—even proposing a partial partition of Poland—with a view to making Poland a hereditary monarchy and to gaining territory for his sons in various parts of Europe. A man of extravagant and luxurious tastes, he cannot be called a good ruler, though he did much to develop Saxon industry and trade and greatly embellished the city of Dresden (founding, for instance, the famous Zwinger art gallery). The Meissen china manufacture was also his creation. He sought to govern Saxony in an absolute fashion and, in spite of his declaration that his conversion was personal only, did much to promote the spread of Roman Catholicism. His wife, Christine Eberhardine, a Hohenzollern, left him when he became a Roman Catholic. Augustus died in Warsaw on Feb. 1, 1733, leaving a son, Frederick Augustus, who succeeded him in Poland and in Saxony, and many illegitimate children, among whom was the famous marshal of France, Maurice de Saxe (*q.v.*).

(EM. R.)

AUGUSTUS III (1696–1763), king of Poland who was also elector of Saxony as FREDERICK AUGUSTUS II, was born at Dresden on Oct. 17, 1696, the only legitimate son of Frederick Augustus I (the future Augustus II of Poland). He followed his father's example by joining the Roman Catholic Church in 1712. In Aug. 1719 he married Maria Josepha, daughter of the Holy Roman emperor Joseph I. He became elector of Saxony on his father's death in Feb. 1733. A candidate at the same time for the Polish crown, he secured the emperor Charles VI's support by assenting to the Pragmatic Sanction and the Russian empress Anna's by recognizing Russia's claim to Courland, and was elected king of Poland by a small minority of electors on Oct. 5, 1733. Helped by the Russians, his troops drove Stanislaw Leszczynski from Poland, and Augustus was crowned in Cracow on Jan. 17, 1734, and was generally recognized as king in Warsaw in June 1736.

On Charles VI's death in 1740, Augustus, as a son-in-law of the previous emperor, Joseph I, claimed a portion of the Habsburg territories. In 1742, however, he was induced to support Maria Theresa, and Saxon troops took part in the Austrians' struggle against Prussia during the Silesian campaigns of the War of the Austrian Succession and again when the Seven Years' War began in 1756. Saxony was in that year attacked by the Prussians, and the Saxon army was forced to capitulate at Pirna in October. Poland, however, remained neutral throughout Augustus III's reign. He was thus able to take refuge in Warsaw, returning to Saxony only when the treaty of Hubertusburg was concluded in Feb. 1763.

Augustus had 11 children and was mostly concerned with dynastic plans. He was content to leave Saxony to the rule of his ministers and Poland under the influence of Russia. His reign was a period of the greatest anarchy in Poland. Between 1736 and his death all diets were brought to nothing by the exercise of the "free veto." After the empress Elizabeth's death (1762), moreover, the house of Saxony lost the support of Russia. In the years 1762–63 his opponents, the powerful Czartoryski and Poniatowski families assisted by Catherine II, were preparing a *coup d'état*. In this troubled situation Augustus died at Dresden on Oct. 5, 1763. He took great interest in music and painting and added to the collection of art treasures at Dresden. His eldest son, Frederick Christian, succeeded him in Saxony. (EM. R.)

AUGUSTUS I (1526–1586), elector of Saxony from 1553, was born at Freiberg on July 31, 1526, the third son of Duke Henry the Pious and Catherine of Mecklenburg. In 1553, on the death of his brother Maurice of Saxony at the battle of Sievershausen (July 7), Augustus inherited not only the electorate but also the leadership of German Protestantism.

In the second half of the 16th century, however, just as the Lutheran theologians were becoming more dogmatic, so were the Lutheran political leaders inclined rather to consolidate the gains made by their predecessors than to concern themselves further with European issues (for instance, the religious conflict in France and in the Netherlands). Thus it was that under Augustus I, who was imperturbably peace loving and loyal to the Habsburg dynasty, Saxony lost its traditional place at the head of German Protestantism to the vigorously Calvinistic Palatinate. Augustus had Maurice's coolly realistic attitude toward politics but lacked his gifts of statesmanship and his wide-ranging intellect. His ambition was governed by considerations of reasonableness and circumspection, and he was always more interested in consolidating and developing territories already won than in making further acquisitions. Idealistic motives were unknown to this hard and unemotional man. He had approved and supported his brother's self-seeking policy in the war of the league of Schmalkalden (by which Maurice had won for himself the electoral title and extensive territories but had also earned the scorn of his coreligionists), but he renounced Maurice's dream of making the Albertine branch of the Wettin dynasty (*see* WETTIN; also SAXONY) a great power in central Germany and, by the treaty of Naumburg (1554), restored the greater part of Thuringia to the Ernestine branch, while securing the rest of his brother's inheritance to his own house. Convinced that neither the Protestant nor the Roman Catholic forces in Germany would win final supremacy, he accepted, as advantageous to himself, the peace of Augsburg (*q.v.*) in 1555, which brought to an end the Reformation proper in Germany. Whereas Maurice had felt himself obliged, as leader of the Protestant princes, to take up arms to induce the emperor Charles V to liberate the two leaders of the league of Schmalkalden, Philip of Hesse and John Frederick I of Saxony (*qq.v.*), Augustus returned to the traditional Albertine policy, namely support for the Habsburgs and the maintenance of peace within the empire.

In his religious policy, in strong contrast to the strict Lutheranism of the Ernestine Wettins of Weimar, Augustus at first followed a Lutheranism tempered by the doctrines of Philipp Melanchthon. When, however, a group of his advisers and theologians tried to lead him toward a moderate form of Calvinism, he proceeded with severity against the "crypto-Calvinists" and, from 1574, directed his ecclesiastical policy along the lines of orthodox Lutheranism. By achieving widespread consent to the "Formula of Concord" he managed to unite most of the Lutheran princes on a doctrinally conservative basis, but this only served to widen the split between the Lutherans and the Calvinists. Despairing of a united Protestant policy within the empire, he detached himself not only from the disturbingly active electors of the Palatinate but also from the Protestants in the Netherlands and from the Huguenots, regardless of their need for help from Germany.

With his own practical approach encouraged by his able and vigorous wife, Anna of Denmark (1532–85), Augustus devoted himself to the economic and administrative development of his lands. His exceptional success in this field won the admiration of

his contemporaries and made his dominion the model Lutheran state.

Augustus had 15 children by Anna of Denmark, including his successor Christian (1560–91). Three months after Anna's death, he married, on Jan. 3, 1586, the 12-year-old Agnes Hedwig of Anhalt (d. 1616). He died, however, a few weeks later, on Feb. 12, 1586, at Dresden.

(WA. HE.)

AUK, generally speaking, any bird of the nonpasserine family Alcidae, short-winged sea divers including the guillemot, murre and puffin. The name is often restricted to the now extinct great auk (*Pinguinus impennis*) and to the razor-billed auk (*Alca torda*). The 22 species of the auk family are restricted to the North Pacific, North Atlantic and Arctic oceans and their coasts. They differ considerably in appearance, ranging from 7 to 30 in. in length and from black to grayish in colour. Most are white below, sometimes with a black throat during the breeding season, and several species have a white wing patch and ornamental head plumes. The bill is often brightly coloured and may be either short and stout, rather long and slender, or laterally compressed and conspicuously sculptured. The compact body is held erect since it is supported by short legs set far back. The feet are webbed.

Auks and their kindred are the most gregarious of birds. They breed in vast, often mixed colonies on ledges of cliffs and in rock crevices or burrows adjacent to the sea; the stormy winter months are spent at a distance from land. The large eggs (one or two) may be white, deep buff or pale green, and either immaculate or variously spotted or scrawled with brown. Being pointed at one end, they tend to roll in a circle and thus avoid falling from exposed nesting sites. Incubation is from 24 to 43 days. In some species the young may be fed in the nest for as long as 40 days, after which they are deserted by the parents. Auks and their relatives are wholly dependent upon the sea for their food, which consists of fish, Crustacea, mollusk and plankton. The largest and most notable member of its family was the great auk, a flightless black-and-white goose-sized bird of the North Atlantic, which was hunted to extinction by seamen in 1844. A few skins, skeletons and eggs have been preserved.

ALBERT E. GILBERT

ONE OF THE AUKS, THE COMMON AMERICAN MURRE OR EUROPEAN GUILLEMOT (URIA AALGE)

The razor-billed auk, also of the North Atlantic, resembles a miniature (17 in.) great auk but has a compressed, white-ringed bill. The cliffs bordering the Pacific coast of North America are populated by numerous other species.

See also GUILLEMOT; PUFFIN. (E. R. BE.)

AULARD, FRANÇOIS ALPHONSE (1849–1928), French historian and one of the leading authorities on the revolutionary period in France, was born in Montbron, Charente, July 19, 1849. Educated at the École Normale Supérieure, he took his doctorate in 1877 and then taught French literature in various provincial universities (1878–84). In 1879 he began the study of parliamentary oratory during the French Revolution and from 1882 until his death in Paris (Oct. 23, 1928), he devoted himself to research in the archives and to the publication of many important contributions to the political, administrative and social history of his chosen period. He was professor of the history of the French Revolution at the Sorbonne from 1887 to 1922, and became president of the Société de l'Histoire de la Révolution française in 1904.

Aulard's principal works include *L'Éloquence parlementaire pendant la Révolution française. Les orateurs de l'Assemblée constituante* (1882); *Les Orateurs de la Législative et de la Convention*, 2 vol. (1885); *La Société des Jacobins*, 6 vol. (1889–97); *Études et leçons sur la Révolution française*, 9 series (1893–1924); *Recueil des actes du comité de salut public*, 16 vol. (1889–1904); *Paris pendant la réaction thermidorienne et sous le Directoire. Recueil de documents pour l'histoire de l'esprit public*, 5 vol. (1898–1902); *Paris sous le Consulat*, 4 vol. (1903–09); *Paris sous le premier empire*, 3 vol. (1914–23); *Taine, historien de la Révolution française* (1907).

See Georges Belloni, *Aulard, historien de la Révolution française* (1949).

AULIC COUNCIL (from Lat. *aula*, "court"), the English name for the *Reichshofrat* or court council of the Holy Roman empire, an organ originally intended for executive work but acting chiefly as a judicature, which worked from 1498 to 1806. Already in the early middle ages the emperor had had his *consiliarii*, but these at first formed only a fluctuating body of personal advisers. From these advisers, some of whom were known as privy councilors or *secretarii*, there grew up in the emperor Henry VII's time (early in the 14th century) a council with permanent and paid members, many of whom were legists. Its business was largely executive, and it formed something of a ministry, but it had also to deal with petitions addressed to the king and accordingly acted as a supreme court of judicature. It was thus parallel to the king's council in medieval England, while by its side, during the 15th century, stood the *Reichskammergericht*, composed of the legal members of the council, in much the same way as the Star Chamber stood beside the English council. The real history of the aulic council, however, begins with Maximilian I, who on Feb. 13, 1498, created a new *Hofrat* to deal with "all and every business which may flow in from the empire, Christendom at large, or the king's hereditary principalities." It was thus to be the supreme executive and judicial organ, discharging all business except that of finance and the drafting of documents. Under Charles V the new institution functioned irregularly, but Ferdinand I set it on a new footing with an ordinance of April 3, 1559. From this date, in rivalry with the *Reichskammergericht*, it dealt with judicial matters and litigation in addition to advising on domestic and foreign affairs. By its ordinance of March 16, 1654, the council authorized the nomination of Lutheran members to it. In the 18th century, with the decline of the *Reichskammergericht*, the importance of the aulic council was correspondingly increased.

The aulic council eventually comprised about 20 members, including its president, its vice-president and the vice-chancellor of the empire. It followed the person of the emperor and therefore had its permanent seat at Vienna; it was paid by the emperor, and he nominated its members, whose office terminated with his life. Its executive powers were small, and it gradually lost all except the formal business of investiture with imperial fiefs and the confirmation of charters, its other powers being taken over by the Geheimrat (privy councilors, already constituted as a definite body for dealing with imperial affairs by 1527). In its judicial aspect the aulic council, exercising the emperor's judicial powers on his behalf, had exclusive cognizance of matters relating to imperial fiefs, criminal charges against immediate vassals of the empire and cases "reserved" for the emperor.

See R. Schröder, *Lehrbuch der deutschen Rechtsgeschichte*, 6th ed. (1919); O. von Gschliesser, *Der Reichshofrat* (1942). (A. LH.)

AULNOY (AUNOY), **MARIE CATHERINE LE JUMEL DE BERNEVILLE,** BARONNE D' (1650 or 1651–1705), French writer, is remembered chiefly for her fairy tales, *Contes nouveaux ou les Fées à la mode* (1698), in the manner of Charles Perrault but with sardonic touches reflecting her personal experience; and also for a number of pseudohistorical novels and secondhand accounts of court intrigue, the most noteworthy being *Histoire d'Hippolyte, comte de Douglas* (1690), *Mémoires de la cour d'Espagne* (1690) and *Relation du voyage d'Espagne* (1691). Married in 1666 to François de la Motte, baron d'Aulnoy, a middle-aged financier, she conspired with her mother and their two lovers to accuse him falsely of high treason. The plot miscarried (1669), and she had to live abroad for many years. Eventually she won success with her writings, which went through many editions and

translations. She died in Paris on Jan. 14, 1705. (J. G. R.-S.)

AULOS, in ancient Greek music the word for "pipe," corresponding to the Latin *tibia* and denoting especially the double pipe sounded by reeds, which, with a variety of names, was the principal wind instrument of most ancient peoples and lasted in Europe up to the early middle ages. The two pipes, of cane, wood or metal, were held one in each hand and sounded simultaneously. The Greeks used double reeds of cane held in the pipes by bulbous sockets. The technical details mentioned by classical authors are too few and too obscure in meaning to explain further how the instrument was played. Typologically similar is the modern Sardinian pipe, the *launedda*. *See* WIND INSTRUMENTS: *Reed Instruments*.

See T. Reinach, "Tibia," in C. V. Daremberg and E. Saglio, *Dictionnaire des antiquités greques et romaines* (1877–1919); C. Sachs, *The History of Musical Instruments* (1940). (A. C. BA.)

AULOS. BRONZE FLUTES DECORATED WITH HEADS OF MAENADS

AUMALE, a town in Normandy (in the modern French *département* of Seine-Maritime, 47 mi. N.E. of Rouen), which gave its name first to a medieval countship, then to a duchy.

The first line of counts of Aumale was founded by Odo of Champagne, brother-in-law of William the Conqueror, duke of Normandy and king of England. The heiress of this line, Hawise, brought the title to her third husband, Baldwin of Béthune, but he died in 1213, and in 1214 William de Fors, Hawise's son by her second husband, William de Fors (d. 1195), was confirmed in the title by King John. When Philip II Augustus of France had annexed Aumale with the rest of Normandy to the French crown, the title count of Aumale was nevertheless retained by William's descendants, these being generally known in English history as earls of Albemarle (one of the many variants of the name Aumale). The countship of Aumale itself was granted first by Philip Augustus to his son Philip, then by Louis VIII of France to Simon, count of Dammartin, whose daughter Jeanne transferred it, together with the countship of Ponthieu, to the house of Castile by her marriage with Ferdinand III (1238). Thence it passed by successive marriages to the counts of Harcourt (1340) and to the house of Lorraine (1476). In 1547 Aumale was made a peerage duchy of France. By the marriage of Anne de Lorraine (1618) the duchy passed to the ducs de Nemours, of the house of Savoy. Louis XIV of France bought it from the house of Savoy in 1686 for his natural son Louis Auguste, duc du Maine, from whom it passed to his brother Louis Alexandre, comte de Toulouse. After the duchy had been transferred to the house of Orléans by the marriage of Toulouse's granddaughter, the title duc d'Aumale was given specifically to Henri (1822–97), fourth son of Louis Philippe, king of the French (*see* BOURBON).

AUMONT, the name of a noble French family. Pierre I d'Aumont (d. 1381) was councilor and chamberlain to John II and to Charles V. Jean V (d. after 1521) governed Burgundy under Louis XII and Francis I. Jean VI (1522–95), knight of the Order of the Holy Ghost in 1578 and marshal of France in 1579, fought against the Huguenots under the last Valois kings but was among the first to recognize Henry IV, who rewarded him with several governments; he died fighting against the duc de Mercoeur's supporters in Brittany.

Jean VI's grandson Antoine (1601–69), also a marshal of France (1651), was governor of Paris (1662) and became the first duc d'Aumont (*duché-pairie;* 1665). Louis Marie Augustin (1709–82), duc d'Aumont, rose to the rank of lieutenant general in the army (1748) but was famous as a connoisseur and collector of works of art and books.

Louis Marie Céleste (1762–1831), duc de Piennes, then duc de Villequier and finally duc d'Aumont, served in the Spanish, in the French royalist and in the Swedish armies, 1793–1814. During the Hundred Days he effected a descent on Normandy.

AUNGERVILLE (AUNGERVYLE), **RICHARD** (1287–1345), commonly known as RICHARD DE BURY, English bibliophile and author of *Philobiblon,* a treatise on the care and study of books, was born near Bury St. Edmunds, Suffolk, on Jan. 24, 1287, and educated at Oxford. His career began in the exchequer at Chester, in the service of Edward of Windsor (later Edward III), and for several years he seems to have been Edward's tutor. In 1326 he joined Queen Isabella and her son in France, and after the prince's accession in 1327, Richard's promotion was rapid. He was in close touch with the king as keeper of the privy seal (1329–33) and was twice sent to the papal court at Avignon, where he met Petrarch. In Oct. 1333 Pope John XXII appointed him to the episcopal see of Durham. In Feb. 1334 he was made lord treasurer, an appointment he exchanged later in the year for that of lord chancellor. This charge he resigned in the next year, but he was repeatedly employed in the king's service abroad and in the defense of northern England.

Richard's large collection of letters, the formulary known as his *Liber Epistolaris*, was probably compiled while he was tutor to Edward. It reveals acquaintance with the foreign correspondence of the chancery, the collections of Pietro della Vigna and of Thomas of Capua and the *Arenge* of Petrus de Loro. As means and opportunity grew, Richard became a patron of scholars and a collector of books; his feeling for books and his experience as a collector inspired the famous *Philobiblon,* which was finished shortly before his death. This book reveals his mastery of rhythmical prose and his ability as a stylist. Richard had lavished his resources on his collection and in the extravagance of a great household, and he died in debt on April 14, 1345. His executors probably sold his library, which was scattered, so that few of his books can now be identified.

The *Liber Epistolaris* was edited by N. Denholm-Young for the Roxburghe club in 1950; the latest edition of the *Philobiblon*, by A. Altamura, was published in 1954.

BIBLIOGRAPHY.—The best critical guide is N. Denholm-Young's "Richard de Bury" in his *Collected Papers on Mediaeval Subjects* (1946). In the *Bodleian Quarterly Record*, vii, no. 80, pp. 325–328 (1933), Denholm-Young revealed the brief but good life of Richard in a Durham chronicle to be a section of a composite work, viz., reminiscences given by William de Chambre, marshal of Durham priory to the monk in charge of the chronicle. On Richard's bibliographical interests, J. de Ghellinck's article in the *Revue d'histoire ecclésiastique*, xviii, pp. 271–312, 482–508; xix, pp. 157–200 (1922–23) is essential. The share of Robert Holcot, to whom the *Philobiblon* has often been ascribed, and who may have been Richard's confessor and prepared and edited some of the manuscripts, has been discussed by B. Smalley in *Archivum Fratrum Predicatorum,* xxvi, especially pp. 8–9 (1956). (F. M. P.)

AUNG SAN (1916?–1947), Burmese political leader, venerated as his country's greatest national hero, was born at Natmauk, Magwe district, in central Burma, of a family distinguished for its part in the resistance movement after the British annexation of 1886. As secretary of the students' union at Rangoon university he, with U Nu, led the students' strike of Feb. 1936. After graduating in 1938 he worked for the revolutionary Dobama Asi-ayon ("We Burmans association"), becoming its secretary-general in 1939. After a secret journey to Tokyo in 1940–41, he became commander in the Burma Independence army which assisted the Japanese invasion of Burma during World War II. In Ba Maw's puppet government he was minister of defense (1943–45). He fell foul of the Japanese over their treatment of the Burmese forces which were reorganized as the Burma National army, founded the Anti-Fascist organization late in 1944 to oppose them and in March 1945, switched his forces to the Allied cause. He next founded the Anti-Fascist People's Freedom league and the People's Volunteer organization to fight for national independence. Becoming deputy chairman of the governor's council on Sept. 26,

1946, he visited London and negotiated the Attlee-Aung San agreement (Jan. 27, 1947) providing for Burma's independence within one year. In the election for a constituent assembly held in April 1947 his party won 196 out of 202 seats. On July 19 he and six of his colleagues were assassinated at the instigation of U Saw, a political rival, in the council chamber in Rangoon while the executive council was in session. (D. G. E. H.)

AUNIS, an ancient province (*pays*) of France, bounded on the north by Poitou, on the west by the Atlantic and on the south and east by Saintonge, and corresponding to the northern part of the modern *département* of Charente-Maritime with the southern part of Deux-Sèvres. Its principal town was La Rochelle (*q.v.*); other towns were Châtelaillon, Marans and St. Jean-d'Angely. Its ancient name (*pagus Alnensis*) may have the same derivation as that of Châtelaillon (*castrum Allionis*). In feudal times Aunis early became subject to the counts of Poitiers and so shared the political fortunes of Poitou. Ecclesiastically it was part of the diocese of Saintes until 1648, when it was joined to the former diocese of Maillezais to form the diocese of La Rochelle. For the administration of justice the presidial of La Rochelle was under the *parlement* of Paris. For military purposes, Aunis constituted a *gouvernement général* which included the islands of Ré and Oléron and had its headquarters at La Rochelle.

See L. de Richemond, *Documents historiques inédits sur le département de la Charente-Inférieure* (1874); L. Papy, *La Côte atlantique de la Loire à la Gironde*, vol. ii (1941).

AURANGABAD, a city in India, headquarters of Aurangabad district, formerly in the dominions of the nizam of Hyderabad (*q.v.*) and after May 1, 1960, in the state of Maharashtra. It is a railway station on the Hyderabad-Godavari line. Pop. (1961) 87,579. The city is situated on the Kaun river, 138 mi. N.E. of Poona and 207 mi. E.N.E. of Bombay. Originally called Khirki, it was founded in 1610 by Malik Amber. Aurangzeb (*q.v.*), who erected there a mausoleum to his wife, which has been compared to the Taj Mahal at Agra, made the city the seat of his viceroyalty of the Deccan and renamed it Aurangabad. It remained the capital of the nizams, after they became independent of Delhi, until they transferred their seat to Hyderabad, whereupon Aurangabad began to decline. In 1956 the district became part of the then Bombay state and the city became the headquarters of a division. Aurangabad is the seat of the Marathwada university, founded in 1958. On the northern outskirts of the city are Buddhist caves (mainly 6th–7th centuries A.D.).

AURANGABAD DISTRICT has an area of 6,314 sq.mi. with a population of 1,532,341 (1961). In the north of the district is the Sahyadri range which includes the Ajanta and Jasna hills, and the main river, the Godavari, flows eastward along its southern border. Its tributaries, the Purna and the Dudhana, have their sources in the Ajanta hills. The southern part of the district is fertile and a variety of crops is raised, including cotton and oilseed. The Kannad and Khuldabad talukas are famous for wheat cultivation and the district has a surplus production of jowar (*Sorghum vulgare*). The chief industries are hand loom and wool weaving, *himroo* (gold brocade) and oil pressing. The Hyderabad-Manmad section of the Central railway passes through the centre of the district. Aurangabad is connected by roads with Jalna, Bhir and Ajanta. The renowned caves of Ellora and Ajanta (*q.v.*) are in the district. The 13th-century fort of Daulatabad (*q.v.*) is also famous. Paithan is an important holy place on the Godavari river and is also the scene of the death of the Vishnuite saint Shri Eknath (17th century). Khuldabad is known for the tomb of the emperor Aurangzeb and other Muslim monuments (14th–18th centuries). *See* also TEMPLE ARCHITECTURE. (M. R. P.)

AURANGZEB (MOHI-UD-DIN MOHAMMED; also called ALAMGIR I) (1618–1707), the last of the great Mogul emperors of India, a zealous Muslim during whose reign (1658–1707) the empire reached its greatest extent but lost its inner cohesion. Born on the night of Nov. 2–3, 1618 (all dates new style), at Dohad in Gujarat, he was the third son of the emperor Shah Jahan (*q.v.*) by Mumtaz Mahal. He received a good education, and his correspondence reflects his scholarly knowledge of Arabic and Persian, of the Koran and the Hadith or traditional sayings of the Prophet. His mother tongue was Urdu, but he also conversed in Hindi and Chagatai Turki. His appointment in 1636 as viceroy of the Deccan provinces first brought him into prominence; but unfriendly relations with his father and the rivalry of his elder brother Dara apparently account for his resignation in 1644. In 1645, however, he was appointed governor of Gujarat; in 1647 he was sent to be governor and commander in chief in Balkh and Badakhshan, as Shah Jahan was attempting the reconquest of the Mogul's ancestral lands in central Asia. Operations against the Uzbeks, however, were indecisive and a severe drain upon the imperial finances. Aurangzeb proved his courage and skill, but the ravaged land could not support his army, and he was ordered to retreat before the winter. In 1648 he was made governor of Multan, to which Sind was added in 1649. In 1649 he was also ordered to relieve Kandahar, besieged by the Persians, but it had surrendered before his arrival, and, lacking heavy siege artillery, he was unable to dislodge the Persian garrison; he had but nominal command of a second attempt in greater force in 1652, which also failed. In summer 1652 he was again appointed viceroy of the Deccan. There he reformed the administration and sought to increase the revenues. His aggressive wars against Golconda (1656) and Bijapur (1657) were both halted by Shah Jahan.

Shah Jahan's serious illness in Sept. 1657 was the signal for a war of succession, in which Aurangzeb experienced little difficulty in destroying his brothers. Shah Jahan himself was closely confined in the fort at Agra from June 1658 until his death in 1666. On July 31, 1658, Aurangzeb crowned himself emperor with the title Alamgir ("Conqueror of the World").

The first half of his long reign was devoted to consolidating his power in northern India. He seized western Assam (1662; lost 1667); quelled the pirates of Chittagong (1666); pacified but could not crush the Pathan tribes in the province of Kabul (1667; 1672–*c.* 1680); and attacked the two principal kingdoms of Rajputana, overrunning Marwar (Jodhpur) in 1679 and making peace with Mewar (Udaipur), after an inconclusive war, in 1681. The second half of his reign, from 1681, was spent fighting in the Deccan, principally against the Marathas. By his conquest of the Muslim Shi'ah kingdoms of Bijapur (1685–86) and Golconda (1685–87), the Mogul empire, then at its most vast, was extended to reach from the Coromandel Coast to Chittagong and the Hindu Kush; but within it the Marathas, unsubdued, grew in strength. His Deccan campaigns proved both a military and a political miscalculation: by long absence from the centres of power and wealth in the north he lost control there; by ceaseless wars he exhausted the imperial treasury and desolated his lands. Despite his narrow efficiency as administrator and general and his masterly duplicity, his authority was everywhere in dispute when his last illness came upon him. This failure was due partly to his reversal of Akbar's policy of conciliating the subject Hindu population.

Unlike Akbar, Aurangzeb was a militant orthodox Sunni Muslim, who had claimed the throne as the champion of orthodoxy against the heretical views of Dara. His accession was followed by increasingly puritanical ordinances enforced by *muhtasibs*, or censors of morals; *e.g.*, the Kalima or Muslim confession of faith was removed from all coins lest it be defiled by unbelievers; and courtiers were forbidden to salute in the Hindu fashion.

His treatment of Hindus was severe: their fairs were prohibited and religious festivals restricted; their idols, temples and shrines were often destroyed; the employment of Hindus in the administration was discouraged; the defiant Sikh *guru* Teg Bahadur was arrested and, refusing to embrace Islam, beheaded; and in 1679 the *jizya* or poll tax on non-Muslims, abolished by Akbar, was reimposed. Furthermore, since Akbar's day the general revenue demand had risen from one-third to one-half of the gross produce. Eventually his inflexible and intolerant policy produced a widespread Hindu reaction; in the Deccan the Maratha revolt spread, and in northern India the Rajputs, Jats, Sikhs and others were prompted to revolt. Aurangzeb died on March 3, 1707, in Ahmednagar, leaving to his successors an empire restless and overstrained.

See J. Sarkar, *History of Aurangzib*, 5 vol., 2nd ed. (1925–30); *Anecdotes of Aurangzib*, 2nd ed. (1925). (P. H.)

AURAY, a town in Brittany, France, in the *département* of Morbihan, lies on the Auray estuary 12 km. (7½ mi.) from the sea. Pop. (1962) 7,802. The town, called Alré in Breton, grew up around the castle and the priory of St. Gildas. The castle, residence of the dukes of Brittany, played an important part in the history of the dukedom. In 1364 Charles of Blois was defeated and killed at Auray, as a result of which the dukedom passed to the house of Montfort (*see* BRITTANY). On the battleground John of Montfort, the victor, built a collegiate church which later became a Carthusian monastery and is now a school for deaf-mutes. In 1442 Duke Francis I married Princess Isabella of Scotland in Auray castle (demolished in 1558). A monument near the monastery commemorates the killing of 952 Chouans (*q.v.*) in 1795; Georges Cadoudal, who was born at Korléano near Auray, was one of the leaders. In 1776 Benjamin Franklin landed at Auray as a member of a commission from America; a plaque is on the house where he stayed and his portrait is in the town hall. The house is in the quarter of St. Goustan where are most of the medieval houses. The Gothic-Renaissance church of Ste. Anne is the largest centre of pilgrimage in Brittany. The chief industry of Auray is furniture making, for which there is a training school in the ancient headquarters of the Knights of the Holy Spirit. The oyster beds of Auray are some of the biggest producers of "natives" in the world.

AURELIAN (LUCIUS DOMITIUS AURELIANUS) (d. A.D. 275), Roman emperor from 270 to 275. A native of the lower Danube, he was a professional army officer when, about A.D. 260, the frontiers of the Roman empire suddenly collapsed. The Persians overran the eastern provinces and Germanic tribes ravaged Gaul and the Balkans and were threatening Italy. In ejecting the invaders, the armies of the east and of the Rhine hailed their respective leaders as emperors. Moreover, Aureolus, whom the legitimate emperor Gallienus had appointed to command a central corps of Dalmatian cavalry in northern Italy, rebelled in 268. Aurelian, with his compatriot Claudius (*see* CLAUDIUS II), then led the loyal cavalry against Aureolus, but successfully conspired to depose Gallienus in favour of Claudius. Claudius died 18 months later, and Aurelian succeeded him as emperor in May 270, despite some three months' opposition from Claudius' brother Quintillus.

Aurelian's achievement was to reunite the empire. A series of battles expelled the Alamanni and their allies from northern Italy; the lower Danube was secured by withdrawing to the left bank the army and civilian population of Dacia, probably in 271. Aurelian then undertook the recovery of the eastern provinces, which for ten years had obeyed the rule of the princes of Palmyra (*q.v.*). Zenobia, regent of Palmyra for her infant son, was captured by autumn 272, and the city taken. After a second revolt Palmyra was looted and its walls leveled.

In 274 Aurelian marched west. Gaul, Spain and Britain were subject to Tetricus. Beset by a German invasion and by conspiracies at home, Tetricus secretly appealed to Aurelian, and, as their armies were preparing for battle near Châlons, deserted to him. The leaderless army of the Rhine was then speedily defeated. Aurelian rewarded the former emperor with the governorship of Lucania.

In Rome, Aurelian began the 12-mi. city wall, much of which still stands. He reformed the coinage and encountered bloody street fighting initiated by the mint workers. He tried to rally the divergent religions of the empire around the cult of the Unconquered Sun and began to surround himself with the ceremonial of divine majesty, telling his armies that it was the god, not they, who made emperors and requiring suitors to kiss his toe instead of his cheek. This enhanced majesty tended to make assassination more difficult, but even so, early in 275, on his way to initiate a campaign against Persia, Aurelian was murdered by a group of officers, allegedly misled by a guilty secretary into believing themselves marked down for execution. The army council then requested the senate to name a civilian ruler, and after six months, during which the government was continued in the name of Aurelian's widow, Ulpia Severina, the senate nominated the elderly M. Claudius Tacitus (*q.v.*). (JN. R. M.)

AURÈS, a mountain massif in northeastern Algeria, fronted by rugged cliffs in the north and opening out in the south into two parallel fertile valleys of the Wadi Abiod and Wadi Abdi facing the Sahara. The region was formerly inhabited by two important aggregations of the Zenaga (*q.v.*; a tribe of Berber origin) —the Jerawa and the Hawara—and by more restricted groups of Jewish origin, like the Ulād 'Aziz, or Arab, like the Ulād Ziyan, which wandered into the region. It is now occupied by the Ulād 'Abdi and the Ulād Daud, who claim descent from Burak the Blind, traditionally an Arab who settled with the first wave of Hilal invasions in the 11th century. (*See* ALGERIA: *History*.)

Christianity spread rapidly through the Jewish community after its introduction *c.* A.D. 185—at one point there were as many as 60 dioceses—but its effect was only superficial and by A.D. 710 it had been replaced by Islam. The last stand for Berber independence was made by the prophetess Kahena at the head of the judaized tribe of the Jerawa. There is no trace of these events in present popular tradition, doubtless because the earlier peoples were driven westward. While Berber is still found in place names and has remained (in a highly corrupt form) the language of love songs, Arabic is the language spoken in the Aurès, through the gradual preponderance of Arab nomads from the Sahara who settled there.

The peasants of the Aurès practise seasonal migration based on villages regulated by collective granaries. Their agricultural customs and their social organization are the same as those in the rest of north Africa. *See* also AFRICA: *Ethnography (Anthropology): North Africa.* (J. H. SE.)

AURIC, GEORGES (1899–), one of the French composers who reacted against the Impressionism of Debussy, was born at Lodève, Hérault, on Feb. 15, 1899. He studied composition under Vincent D'Indy in Paris, and in 1920 became associated with Francis Poulenc (*q.v.*) as a member of "Les Six," the group of composers sponsored by Jean Cocteau. In his early works he developed a type of musical irony, mingling popular tunes with sophisticated harmony. The series of his skilful scores for French, English and U.S. films began with *Le Sang du poète* (1931). His first three ballets were produced between 1924 and 1927 by Serge Diaghilev, and his later ballets by Jean Louis Barrault, Cocteau and Roland Petit.

See Antoine Goléa, *Georges Auric* (1958).

AURICULA (*Primula auricula*), an alpine plant and a favourite spring flower. It thrives best in a cool soil and shady situation. The florists' varieties are grown in rich composts.

Auriculas are best germinated in a cold frame or cool greenhouse, in September or October, in a rich but light soil. They can be planted in the rock garden or border, preferably in mild climates, the following spring. Auriculas may also be propagated by offsets or division, which is to be done in early spring. When seed has been saved from the finer sorts, the operation is one of considerable nicety since it not infrequently happens that the best seedlings are at first exceedingly weak. They generally flower in the second or third year, a few good sorts being all that can be expected from a large sowing. The summer heat in the United States makes the cultivation of auriculas rather difficult.

AURICULAR CANAL, the tube leading from the external ear to the eardrum. It is about one inch long and is lined by thin skin which is tightly bound to the cartilage and bone on which it rests. The outer one-third is formed by cartilage, the inner two-thirds by bone. The few short crisp hairs at the entrance of the canal serve as a barrier to dust and small insects. In the skin of the outer portion are glands which secrete a sticky yellow material called cerumen, or wax. This also serves to catch small particles. The cerumen sometimes becomes packed in, causing hearing impairment, and should then be removed by a physician. The short straight, constricted tube connecting the auricular with the ventricular portions of the embryonic heart is also known as the auricular canal. *See* also EAR, ANATOMY OF; HEART, ANATOMY OF; NERVOUS SYSTEM.

AURIGA (the charioteer), in astronomy, a conspicuous constellation in the Milky Way which passes nearly overhead in middle northern latitudes in the evenings of winter. It was symbolized by the Greeks as a man holding a goat and two kids in

his left arm and a bridle in his right hand. The brighter stars of the constellation, including a star of the neighbouring Taurus, outline a muffinlike figure. The brightest of these is Capella, one of the three brightest stars of the northern celestial hemisphere; it is a yellow giant star at the distance of 45 light-years.

A small triangular figure southwest of Capella, marking the place of the kids, includes the star Epsilon Aurigae, an eclipsing double star revolving in the unusually long period of 27 years. (R. H. Br.)

AURILLAC, the capital of the *département* of Cantal in Auvergne, south central France, lies on the banks of the Jordanne, 2,040 ft. above sea level, dominated by the Cantal mountains to the north. Pop. (1962) 23,179. The Palais de Justice (1872) in neo-Greek style and the Gothic church of Notre Dame aux Neiges (1339) are in the central square of the town. Among the houses of the old quarter stands the church of St. Géraud (founder of the town in the 9th century), which incorporates parts of two 10th-century churches. The castle, which has an 11th-century dungeon, is now used as a school. The J. B. Rames museum, with its galleries for local natural history, as well as for regional prehistory and folklore, is the cultural centre of Aurillac. There is a big municipal library. The first French pope, Gerbert, who was known as Silvester II (999–1003), was educated at the old Benedictine abbey of St. Géraud, founded in 894. Aurillac is on the railway from Clermont-Ferrand to Toulouse. It is a communications, commercial and tourist centre for the Cantal, where the raising of cattle and the production of dairy foods are the most important industries. Two Cantal cheeses, Fourme and Bleu d'Auvergne, are specialities. At the many fairs, some surviving from the middle ages, cheeses, cattle and horses are bought and sold. Some of these products are exported. Many small enterprises include the making of umbrellas, gloves, fishing nets, confectionery and leather goods. (He. D.)

AURIOL, VINCENT (1884–1966), French statesman, president of the Fourth Republic from 1947 to 1954, was born at Revel, Haute-Garonne, on Aug. 27, 1884. A lawyer and journalist at Toulouse until his election as deputy in April 1914, he became secretary-general of the Socialist parliamentary group in 1919. In Léon Blum's first government (June 1936–June 1937) he was minister of finance and as such was responsible for devaluating the franc in order to meet his country's financial crisis. In July 1940, during the collapse of France in World War II, he was one of the 80 French parliamentarians who voted against according full powers to Marshal Pétain. Arrested in Sept. 1940, he was released in April 1941. Having gone into hiding in Oct. 1942, he escaped to London in 1943. He was a member of the French Consultative Assembly in Algiers and in Paris and, in Nov. 1945, joined Gen. Charles de Gaulle's government as minister of state. In 1946 he was president of both the first and the second Constituent Assembly. Elected president of the republic on Jan. 16, 1947, he strove constantly to make the machinery of the new constitution work. At the end of his term (1954), he refused to stand again. He resigned from the Socialist Party in December 1958. Under the Fifth Republic, he became a *de jure* member of the Constitutional Council (1959) but ceased to sit on it from July 1960, in protest against the new regime's tendency to arbitrate rule. He died in Paris on Jan. 1, 1966.

AUROBINDO, SRI (1872–1950), Indian seer, philosopher, poet and patriot, was born in Calcutta on Aug. 15, 1872. He was educated at Loretto Convent school, Darjeeling, before going to England in 1879 where he continued his schooling and then read classics at Cambridge. He returned to India in 1893 and joined the Baroda state service. For the next 17 years, in Baroda and later in Calcutta as principal of the new National college, Aurobindo was one of the revolutionary nationalist leaders agitating for independence. At the same time he was initiated into yoga. After his trial and acquittal in connection with a bomb case in 1908, he left politics and in 1910 retired to Pondicherry, where he continued to live until his death on Dec. 5, 1950.

Sri Aurobindo's political life had been inspired by spiritual motives, and afterward he devoted himself to discovering the way by which the universe might be made divine. With the collaboration of a French woman, endowed with rare spiritual qualities, called the Mother, he founded an *ashram,* or settlement, which grew into an institution with a centre of education attached to it. It is distinguished by having no creed or ritual other than the practice of meditation and concentration. Its inmates are not ascetics but ordinary men and women who are assigned specific duties which they perform in a spirit of love.

The message of Sri Aurobindo's philosophy is one of hope, for he envisaged cosmic salvation in which man and the universe are destined to become divine. This is decreed by the law of evolution; for as creation is the descent of the Absolute Spirit (Sachchidananda) into supermind, mind and matter, so evolution is the ascent of matter to life, mind and supermind and finally to Sachchidananda. So far only the first three stages of evolution have emerged, but the time has come for evolution to take the step that will carry it to the supermind and change the nature of the universe, a change from death to deathlessness, from finite to infinite and from imperfection to perfection.

Sri Aurobindo has been acclaimed as the prophet of the superman, as the hierophant of the "new age." His superman is the God-man, the gnostic being who excels man not in physical power but in things of the spirit and is not to be confused with the superman of Nietzsche. Similarly, Sri Aurobindo's humanism is clearly different from the restricted humanism of western philosophies. He has called his standpoint that of a "spiritual religion of humanity."

Sri Aurobindo's works are very numerous, comprising writings on philosophy, yoga, sociology and politics, as well as poems, plays and literary criticism. Among his chief books are *The Life Divine* (1940), *Essays on the Gita* (1928), *The Synthesis of Yoga* (1948), *Savitri: a Legend and a Symbol* (1950).

For an account of his life and lists of his works *see* A. B. Purani, *Life of Sri Aurobindo* (1958); K. R. Srinivasa Iyengar, *Sri Aurobindo: a Biography* (1950); *see* also publications and lists of the Sri Aurobindo Ashram. (S. K. Ma.)

AUROCHS, the extinct wild ox of Europe (*Bos taurus primigenius* or *B. primigenius*), from which domestic cattle are descended. It was mentioned by Julius Caesar as the "urus," and, known as *tur*, survived in Jaktorow forest of central Poland until 1627; engravings after an oil painting of 1500 show its conformation and colour. It was enormous, six feet high at the shoulder, black in colour and with spreading, forwardly curved horns. Skulls and bones of the aurochs are common in Pleistocene deposits in England and on the continent of Europe. Some breeders in Germany have claimed that they have re-created this race since 1945 by crossing Spanish fighting cattle with longhorns and other breeds. Their animals have a superficial resemblance to the aurochs with the exception of its great size, but the genetic constitution cannot be identical. The semiwild park cattle of Chillingham, Eng., and elsewhere are not directly descended from the aurochs; they show greater affinity with the Bronze Age shorthorn (*B.t. longifrons* or *B. longifrons*), a later mutation of the aurochs. The name aurochs has sometimes been erroneously applied to the European bison (*q.v.*) or wisent. *See* also Buffalo. (L. H. M.)

AUROCHS (BOS TAURUS PRIMIGENIUS), WOODCUT FROM HISTORIA ANIMALIUM BY KONRAD VON GESNER, 16TH-CENTURY NATURALIST

AURORA, Latin for Eos, the Greek personification of the Dawn, a purely mythological figure, not a goddess with a cult. According to Hesiod she was the daughter of the Titan Hyperion and Theia, and sister of Helios and Selene. By the Titan Astraeus she was the mother of the winds Zephyrus, Notus and Boreas, of Hesperus and the stars; by Tithonus she was the mother of Memnon (*q.v.*). Homer represents her as rising every morning from the couch of Tithonus and drawn out of the east in a chariot to carry light to gods and men. From the roseate shafts of light

that herald the dawn, she bears in Homer the epithet "rosy-fingered."

Aurora is also represented as the lover of the hunter Orion, the representative of the constellation that disappears at the flush of dawn; and of the youthful hunter Cephalus, by whom she was the mother of Phaëthon (*q.v.*). In works of art Eos is represented as a young woman, fully clothed, walking fast with a youth in her arms; or rising from the sea in a chariot drawn by winged horses; sometimes, as the goddess who dispenses the dews of the morning, she has a pitcher in each hand.

In Latin writings the word Aurora was used (*e.g.*, by Virgil) for the east. (T. V. B.)

AURORA, a city of Kane county, Ill., U.S., on the Fox river, 39 mi. W. of downtown Chicago. Founded as a trading point and mill site near a Potawatomi village in 1834, the townsite was platted in 1836. Aurora was incorporated as a city in 1857.

Aurora is both a residential and an industrial city. Its major industrial enterprises include the manufactures of machinery, metal furniture and fixtures; and printing and publishing. Many residents commute to Chicago to work. Aurora college, founded in 1893 by the Advent Christian Church of America and administered and supported by its members, is located there. Recreation facilities are available in the Fox Valley Park district and in municipal parks.

The city's population was 63,715 in 1960. For comparative population figures *see* table in ILLINOIS: *Population*. (WA. B. H.)

AURORA BOREALIS: *see* AURORA POLARIS.

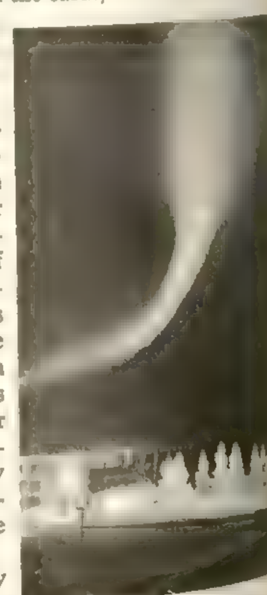
AURORA POLARIS, or the polar light, is a familiar and often beautiful sight in high latitudes. In the northern hemisphere it is called the aurora borealis or northern lights, and in the southern hemisphere, the aurora australis or southern lights. This light is not a reflection, like the rainbow, whose apparent position depends on where the observer stands; the aurora comes at any instant from definite places in the atmosphere, where the air is for the time luminous like a flame. But the auroral light is not due to something burning away, like a gas jet; it is more akin to the light from an electric discharge bulb. The lights are called polar or (in the northern hemisphere) northern because they are most commonly seen in high latitudes; only rarely are they visible in southern Europe or the southern United States. Yet when seen in these lower latitudes the appearance at times is very striking; it is therefore not surprising that several of the ancient Mediterranean authors, Greek and Roman, refer to it. Not unnaturally, in earlier times, and particularly during the dark ages, the northern lights were viewed with superstition, in parts of Europe where they were seldom seen, as divine portents of coming calamities.

In each hemisphere the aurora appears most frequently in a belt called the "auroral zone" that lies about 20° to 25° from the earth's magnetic axis pole. In the northern hemisphere this pole is near Thule in northwest Greenland. On the average the auroral zone, where auroras appear on almost every clear night, extends from north central Alaska through Labrador and northern Norway. Outside the zone displays are seen less frequently, but they are often observed in the northern United States and Europe and on rare instances have been seen as far south as Mexico City and Greece. The zone is not stationary but shifts toward the equator during the time of sunspot maximum and toward the pole near sunspot minimum. At latitudes below the auroral zone this shift helps provide an increased number of displays near sunspot maximum. Through the year auroras most often occur from March to April and from September to October.

There is some correlation between the occurrence of auroras and activity on the surface of the sun. On a statistical basis it appears that an aurora, if it can be associated with a particular solar flare, is likely to follow the flare after a period of one day or so. This delay time suggests that the disturbance is propagated to the earth with an average speed of about 1,000 miles per second, or somewhat less than 1% of the speed of light.

The aurora has many connections with the earth's magnetism; the centres of the auroral zones are close to the ends of the earth's magnetic (rather than geographical) axis, and the highest point of a distant auroral arc is usually nearly in the direction of the magnetic north. The auroral bands extend from east to west in a direction nearly perpendicular to the compass direction, and the rays and flutings of the bands, and the bands themselves, are not vertical, but are inclined to the vertical nearly along the direction taken by a freely balanced magnetic needle at the spot where the aurora is located: that is, along the direction of the magnetic dip. Moreover the aurora is most active, and advances farthest toward lower latitudes, when the earth's magnetic field is highly disturbed, corresponding to what is called a magnetic storm. At such times telegraphic and radio transmissions are likewise usually disturbed, and even electric power lines may be put out of action. Such occurrences tend to coincide with the presence of active spots and eruptions on the sun's visible disk. Like sunspots, they wax and wane in frequency and intensity in the course of the 11-year sunspot cycle.

The origin of the aurora is not well understood. The symmetry of the auroral zones about the earth's magnetic poles suggests that electrically charged particles are guided to earth by the magnetic field and these particles cause the auroral light. The relationship between solar and auroral-magnetic activity suggests the sun as the source of these particles. This viewpoint was supported by L. Vegard's discovery in 1939 that the auroral spectrum contained light emitted by hydrogen. A. B. Meinel found in 1951 that this hydrogen emission was slightly bluer than similar light in the laboratory, which demonstrated that the hydrogen gas was bombarding the earth with speeds up to several thousand miles per second. Still, the manner in which hydrogen and perhaps other elements ejected by the sun in ionized gas clouds or streams is able to penetrate the earth's magnetic field and produce an aurora is not fully understood. Although various theories have been proposed for the propagation of solar gas through interplanetary space and the eventual bombardment on the earth, none of these theories has been successful in explaining the auroral zone along with the height and appearance of the auroral forms.



PHOTOGRAPH, V. P. HESSLER

THE AURORA BOREALIS. PHOTOGRAPH TAKEN IN ALASKA

It is likely that auroral excitation is produced by the bombardment of protons (hydrogen nuclei) and electrons on the upper atmosphere with speeds of hundreds and even thousands of miles per second. A collision between one of these fast particles and an atom or molecule in the upper atmosphere produces a quantum of light whose colour is characteristic of the atom or molecule involved. In an average auroral display probably 100,000,000 protons and electrons strike one square inch of the earth's atmosphere per second.

In the 18th century fairly successful attempts were made to determine the actual height and location of the aurora in the atmosphere, by observing its direction from two places miles apart. Such determinations are nowadays made by photographs taken simultaneously from two or more distant stations, connected by telephone. These observations were initiated in Norway by Carl Störmer; auroras seen from Oslo may be located high in the atmosphere over Norway, or may be over the Arctic sea to the north of Norway, or sometimes to the south over Denmark or Germany. Commonly, the aurora is most extended along a nearly east-west direction, parallel to the auroral zone. Though at times it appears as a diffuse formless volume of luminosity, its most distinctive form is that of a long wavy band or curtain, often with folds and flutings in it, high up in the sky, with the lower edge at about the same height above

the earth all along the band. Though its lower edge is thus nearly horizontal, the band appears as an arc or arch, owing to perspective, when seen from afar (usually, in Europe or the United States, to the north). The band may extend to right and left down to the horizon. Sometimes the aurora is visible almost overhead, and when it can be seen "edge on" it is evident that it is extremely thin; thus in this respect also it is like a curtain, thin compared with its breadth and its length from top to bottom. The lower edge of an auroral band is often at a height of about 70 mi. Its height is seldom much less, though it may be decidedly greater (up to 100 mi. or more). The bands or curtains sometimes extend upward to very great heights, of 400 or even 500 mi., though the distance from lower to upper "edge" (the latter especially is often ill-defined) may on other occasions be only 20 or 30 mi.

It has been found that the highest auroras are in regions of the air which lie within the rays of the sun's light, though the sun may be several degrees below the horizon of the observer. These very high auroras give direct evidence of the presence of appreciable air at unexpectedly great heights. Owing to their great height above the ground auroras can be seen from very distant places, and an aurora seen low above the horizon will be several hundreds of miles away.

The appearances of auroras are most varied; more than one arc or curtain may be visible at once, and they may change and appear and disappear with great rapidity, though also they may long remain constant, or move only slowly across the sky. Sometimes, when it is nearly overhead, one can look up into a great fold in an auroral drapery, so that the rays or flutings along it, seen in perspective, seem to converge toward a point: such an appearance is called an auroral corona. The fine rays that form draperies and coronas are often only a few hundred feet in diameter.

Faint auroras may appear colourless; for the brighter auroras the most common colour is yellow-green, which is produced by atomic oxygen at low pressure. The higher auroras may show red, which arises from atomic oxygen at still lower pressure. An active aurora may on rare occasions show red on the lower border of an otherwise green display. The red in these cases arises from molecular nitrogen (N_2) and ionized molecular oxygen (O_2^+). The high sunlit auroras may show a bluish tinge, produced by ionized molecular nitrogen (N_2^+). (S. Cn.; J. W. Cn.)

AURUNCI, the name of an ancient tribe of Campania, in Italy, that occupied the strip of coast in what is now the province of Caserta, between the Volturnus and Liris (Volturno and Liri) rivers, with its capital at Suessa (modern Sessa Aurunca). The Romans conducted a succession of campaigns against them between *c.* 345 and 295 B.C., when they were completely exterminated. No record of their speech survives, but their geographical situation and the frequency of the *co*-suffix in that strip of coast suggest that they spoke the same language as their northern neighbours the Volsci (*q.v.*). Ausones, the Greek form of the name Aurunci, came to denote the inhabitants of the whole of Latium and Campania.

AUSCHWITZ: *see* Oswiecim.

AUSCULTATION, a medical term applied to the act of listening to sounds within the body in order to detect certain defects or conditions, such as heart valve malfunctions or pregnancy. Auscultation originally was performed by placing the ear directly on the chest or abdomen, but it has been practised mainly with a stethoscope since R. T. H. Laënnec invented that instrument in 1819.

The technique of auscultation is based on characteristic sounds produced, for example, in the head and elsewhere by abnormal blood circuits, in the joints by roughened surfaces, in the lower arm by the pulse wave and in the abdomen by an unborn child or intestinal disturbances. However, it is most commonly employed in diagnosing diseases of the heart and lungs.

The heart sounds consist mainly of two separate noises occurring when the two sets of heart valves close. Either partial obstruction of these valves or leakage of blood through them because of imperfect closure results in turbulence in the blood current, causing audible, prolonged noises called murmurs. In certain congenital abnormalities of the heart and the blood vessels in the chest, the murmur may be continuous. Murmurs are often specifically diagnostic for diseases of the individual heart valves; that is, they sometimes can determine which heart valve is causing the heart condition. Likewise, modification of the quality of the heart sounds may reveal disease or weakness of the heart muscle. Auscultation is also very useful in determining the types of irregular rhythm of the heart and in discovering the sound peculiar to inflammation of the pericardium, the sac surrounding the heart.

Auscultation also reveals the modification of sounds produced in the air tubes and sacs of the lungs during breathing when these structures are diseased.

See Diagnosis: *Auscultation.* (H. B. Sp.)

AUSGLEICH, a German word meaning treaty, compact or compromise. It is specifically used to describe the compact, finally concluded in Feb. 1867, that regulated the relations between Austria and Hungary following the establishment of the dual monarchy. *See* Austria, Empire of.

AUSONIUS, DECIMUS MAGNUS (*c.* 310–*c.* 393), Latin poet and rhetorician remarkable chiefly for his preoccupation with the provincial scene in Gaul, was born of Gallic stock at Bordeaux, where his father practised medicine. After the usual education in "grammar" and rhetoric, first at Bordeaux, then under his uncle Arborius at Toulouse, he began to teach in the famous schools of his native town, first as *grammaticus,* then as rhetor. His success is attested by his call to Trier (*c.* 365) by Valentinian I to superintend the education of Gratian, who, on his accession, elevated Ausonius first to the prefecture of Africa, Italy and Gaul, then to the consulship in 379, thereby proving Juvenal's assertion about the power of fortune to make consuls out of rhetoricians. Gratian's murder in 383 ended these years of eminence, and Ausonius returned contentedly enough to his estates on the Garonne to cultivate friendship and literature. Though he was a Christian, it was only in the sense that he was not a pagan, and his last years were saddened by the incomprehensible conduct of his pupil Paulinus (later bishop of Nola), who deserted literature for a life of Christian retirement. Nothing could make Paulinus see reason, and Ausonius's death concluded their correspondence on this inexpressibly painful subject.

An incorrigible trifler and victim of what he called *poetica scabies,* Ausonius has left few works of any consequence. His prose work, *Gratiarum actio* ("thanksgiving"; *i.e.,* for the consulship), is a composition of surpassing dullness and childishness. His longest poem, on the Moselle (*Mosella*) river, has flashes of an almost Wordsworthian response to nature, never a common quality in Latin literature, but its rhetorical flavour spoils it for modern readers. *Cento nuptialis* is a patchwork in which lines of Virgil are pieced together to form a shockingly explicit account of the consummation of a marriage. Ausonius reveals a sentimental fondness for old associations in the works of his retirement, *Parentalia,* a series of poems on deceased relatives, and *Professores Burdigalenses,* on the professors of Bordeaux, delightful portraits that give a valuable picture of the lives of quiet provincial people. *Ephemeris* is a somewhat self-conscious account of the daily round. A characteristic piece of trifling is the *Technopaegnion,* a set of hexameter poems in which each line ends in a monosyllable. Of his epistles may be mentioned the correspondence with Paulinus and Symmachus. There are useful autobiographical *Praefatiunculae; Eclogae,* mnemonic verses on astronomy and astrology; *Ordo urbium nobilium* ("order of noble cities"); *Ludus septem sapientum* ("play of the seven sages"), a forerunner of the morality play; many epigrams, including adaptations from the Greek Anthology, and a vast assortment of learned curiosities.

AUSSIG: *see* USTI NAD LABEM.

AUST-AGDER, a *fylke* or county of south Norway, extends 105 mi. northwestward into the mountains from the coast line on the Skagerrak. Pop. (1960) 77,061. Area 3,562 sq.mi. Pre-Cambrian bedrock covers the county, which has a broken and uneven landscape. Setesdal valley in the west is bounded by steep mountains reaching to 3,500 ft., while the branching valleys in the middle of the county are divided by smaller hills. The uplands are covered with sandy morainic drift giving sufficient soil for coniferous forests. Nearly 75% of the population lives in the coastal district where the towns of Arendal (seat of provincial administration, pop. [1960] 11,425), Risor, Grimstad and Lillesand are situated. Until the middle of the 19th century these were important ports for exporting timber, but they are now commercial centres with a few industries. Summer tourists are attracted to the coast, Lillesand, with its white-painted wooden houses, being especially popular. Horticulture is carried on in some areas, while in the middle valleys the main occupation is forestry, and in Setesdal, livestock products. The railway and main road from Oslo to Stavanger pass through Aust-Agder, and bus services connect the rural districts with the towns. (L. H. HG.)

AUSTEN, JANE (1775–1817), English novelist, was born on Dec. 16, 1775, the second daughter and seventh child of George Austen, rector of the parishes of Steventon and Deane in Hampshire, and of his wife Cassandra Leigh. The Austens were of Kent, the Leighs of Gloucestershire and Warwickshire, and on both sides were connections with the academic clergy of Oxford. Jane Austen, like her brothers and her sister Cassandra, was born in the parsonage of Steventon, which remained her home for the first 26 years of her life. In 1801 her father resigned his duties to his eldest son, James, and retired to Bath, where he died in 1805. Not until 1809, when the third son, Edward, provided his mother and sisters with a home on his Hampshire property at Chawton, were they again settled in a house of their own. Chawton was Jane Austen's home until she went to Winchester in May 1817, in search of medical attention. She died there on July 18 and was buried in the cathedral.

Although neither foreign travel nor public life diversified the even tenor of her way, Jane Austen spent considerable periods in the homes of three of her brothers: James at Steventon, Edward (who had been adopted as heir by Kentish cousins) at Godmersham, Henry in London—besides paying visits to friends and relatives. The narrowness of her experience and meagreness of her opportunities have been exaggerated. Likewise, when her life is described as uneventful, it should be remembered that two of her brothers, Francis and Charles, were sailors in a time of almost continuous naval warfare. It is of such events that women's lives have consisted.

Composition and Publication.—In respect of only half Jane Austen's novels are the dates of composition and publication directly related, and a chronological account must reckon with revision, work left uncompleted, and work never designed for publication. From an early age (certainly before 16), she was writing burlesques of current fashions in fiction, and her "Plan of a Novel," prompted by an occurrence in 1815, shows that she did not lose her zest for this game. By 1792, however, she was engaged on a piece of serious fiction, "Kitty or the Bower," which interested her enough to prompt subsequent revision; yet a year later she was making fair copies of some of the juvenile burlesques. In 1795 she completed a novel in the form of letters, "Elinor and Marianne," which was to afford the basis of *Sense and Sensibility*. Between 1796 and 1797 she was writing "First Impressions," which, after considerable revision, was to appear as *Pride and Prejudice*. The manuscript was rejected by Thomas Cadell. In 1798–99 she wrote *Northanger Abbey* (then called "Susan," after the original name of its heroine). This manuscript, after undergoing some revision, was sold in 1803 to Richard Crosby, who took no steps to publish it. To the unsettled years in Bath and Southampton belong only *The Watsons*, a fragment, and *Lady Susan*, probably set aside unfinished and completed, half in jest, on the occasion of making a fair copy. Thus, when Jane Austen had once more a settled home, at Chawton, she had in hand the manuscripts of three completed novels, and, before her first published work appeared, she was already engaged on one of the novels of her maturity: *Mansfield Park* was begun in Feb. 1811, *Sense and Sensibility* published in November of that year. Meanwhile she was at work again on "First Impressions," which, as *Pride and Prejudice*, was completed by Nov. 1812, and appeared in Jan. 1813. *Emma* was begun in Jan. 1814; *Mansfield Park* appeared in May of that year. In the summer of 1815, *Persuasion* was begun, and in December of that year *Emma* was published. This was the last of her novels that Jane Austen was to see in print: she completed *Persuasion* in July 1816, but rewrote the end in August. Between January and March of 1817 she was at work on the fragment we know as *Sanditon*. *Northanger Abbey*, which she now referred to as "Catherine," had been bought back from Richard Crosby in 1816, and reconsidered for publication, but set aside once more; it was published with *Persuasion* in the winter after her death.

The Novels.—When Jane Austen decided to risk financial loss by publishing *Sense and Sensibility*, she had grounds for misgiving, two of her three completed novels having been, in effect, rejected for publication. She never, however, lacked appreciation and encouragement at home. All her transactions with publishers were conducted by her father or one of her brothers; and it was evident from the fair copies she made of this or that piece of juvenile burlesque for one and another of her family circle that the welcome given to it there had outlasted the original occasion. The perpetuation of her delight in the improbabilities and other absurdities sanctioned by the tradition of the 18th-century novel may have owed something to their being a shared joke: she refers to her family as "great novel-readers and not ashamed of being so." Her own enjoyment of Richardson is on record, and can be inferred from her novels, if due allowance is made for differences of time and temperament. Her taste in reading may have been virtually formed by the time she began writing for publication—that is, some years before the end of the 18th century; but it amused her, when she revised her manuscripts, to bring the literary allusions in them up to date; and a reference in a letter of 1814 shows that she was even then in no doubt as to the identity of the author of *Waverley*.

Although her surviving references to her own work are few, informal, even playful—they almost all occur in family correspondence—yet their fundamental consistency allows some inferences to be drawn as to the principles of her art. Keenly aware to the end, of the power of convention over the novelist—even *Sanditon* glances ironically at the situation to be expected in a novel—she valued fidelity to observed truth, and believed in keeping the subject well within range of observation. The point of view from which each story is related remains constant; though we may have something to learn from the conversation of any of her characters (whether directly or ironically conveyed), and must always listen for the occasional, unobtrusive comment in the narrator's own voice, yet the heroine remains firmly established at the centre of the composition; her mind is fully opened to us (more fully, sometimes, than to herself); to her judgment, even when it is clouded by prejudice, to her sensibility, even when it is coloured by love, every issue of significance is referred. What is withheld from her—the former transactions between Darcy and Wickham, the change in Captain Wentworth's feelings for Anne—can never be fully intelligible to us until she is apprised of it, though sufficient intimations are vouchsafed to prevent a false impression from taking hold. Notwithstanding this focus of Jane Austen's attention on her heroines (reflected in talk and in letters—Elizabeth Bennet was to her "as delightful a creature as ever appeared in print," Emma Woodhouse a heroine whom no one but herself would much like, Anne Elliot almost too good for her), in none of them can we discern any inclination toward self-portraiture. Moreover, the world that is reflected in this carefully arranged mirror of their consciousness is smaller than that

with which she was herself acquainted. "Three or four families in a country village," she observed contentedly, "is the very thing to work on." By the time she wrote that, she was familiar with London, as she had not been when she carried Elinor and Marianne Dashwood thither; but she had come to prefer that it should be a place known chiefly by hearsay to her central character, visited rather by Harriet Smith than Emma.

Jane Austen's art is selective to an uncommon degree. She took or discarded what she deemed requisite, not only from the stuff of her own observation and experience but also from the matter and manner of the English novel, especially as it had developed since Richardson's *Pamela*. It may have been from the novel-in-letters that she derived the notion of constructing her plots with reference to the almanac of a particular year; and its fixed vantage point is likely to have suggested the importance of establishing a point of view in the consciousness of a central character. In her development of this convention, however, she obtained an instrument of greater flexibility than any series of fictitious letters could afford. Other elements in the tradition of the novel she rejected or altered radically. It was not against the assumptions of Gothic romance alone that she saw reason to discriminate: even the novel of domestic life had not disencumbered itself of artifices derived from the stage, notably from sentimental comedy—emphatic and symmetrical plots, formal and arranged passages of witty dialogue, and the lavish use of an unknown quantity to assist the arithmetic by which mischance and misunderstanding add up to "happy ending." When Jane Austen acknowledged that Catherine Morland's circumstances were inauspicious, since "there was not one family among [her] acquaintance who had reared and supported a boy accidentally found at their door—not one young man whose origin was unknown," she was shaking one of the pillars of the conventional novel. Her own use of coincidence was sparing and discreet. Few of the hindrances she opposes to love—that is, to the eventual happiness of her sympathetic characters—spring solely from incident; their source is rather to be found in temperament and the sum-total of circumstances. The crisis of each novel (with the possible exception of *Mansfield Park*) is to be understood in terms of self-discovery, on the part of hero or heroine or both; and, for a condition of things in which they may misinterpret their own or one another's feelings, she requires little more than a family of which the natural head has abdicated his authority, like Mr. Bennet or Mr. Woodhouse, misused it, like Sir Walter Elliot, misdirected it, like Sir Thomas Bertram—or shirked his responsibility, like John Dashwood. As a precipitant of the unfavourable circumstances thus produced, she is generally content to use a newcomer to that village in which her "three or four families" are settled: a prepossessing young man whose morals prove to be inferior to his manners, but who can seldom be characterized by a much harsher term than opportunist. "Pictures of perfection . . . make me sick and wicked," she wrote, with regard to idealized characters; she might well have spoken in equally strong terms of unmitigated badness. Even for the odious Mrs. Norris she can find excuses; and she sets narrow bounds to the harm done by foolish or reprehensible conduct, or by ill nature. "Guilt and misery" are not ignored, but they are conveyed to our imagination through their impact on those "not greatly in fault themselves," whom she is "impatient to restore . . . to tolerable comfort"; and so their effects are transient.

Jane Austen's selective process is directed not only by her fidelity to what she judged probable and what she knew herself capable of representing but also by obedience to her own comic vision. There have always been readers to maintain that she ignores too much of life, but what she leaves out never falsifies what she puts in, because of her incorruptible consistency. The perspective is true, because the parts are justly related: characters exert the right degree of pressure on one another, and the dialogue carries that part of the responsibility for acquainting us with their interaction which it is fitted to bear. Judged as a medium of communication, and compared with that of other novelists, it appears both delicate and tough: for the sake of elegance and clarity, differences are minimized—after *Sense and Sensibility*, we find no downright vulgarisms—but a sense of the uniqueness of the individual is not lost in the process. Nor, on the other hand, is the function of dialogue sacrificed to the demands of character and the delight of the ludicrous: it is not always realized with what essential economy Miss Bates conveys to us information regarding events to which she alone can bear witness. Thus, the wit of Henry Tilney or Elizabeth Bennet, the dry humour of Mr. Bennet and the pleasantries of the Crawfords never resemble those passages in stage comedy which, being offered for their own sake, must sometimes be bought at the price of verisimilitude. Furthermore, they remain in harmony with the narrator's own comments; for what is witty in both may be imagined as spoken without premeditation. It displays no coruscating facets, no jet of epigram nor play of metaphor. It consists primarily in a command of well-timed understatement, whose meaning is gradually perceived. She expected of her readers just such a close and lingering attention as she had given to her writing.

Reputation.—Jane Austen's literary reputation established itself unobtrusively but steadily. Within her own generation she obtained recognition: Scott was among her earliest and most spontaneous admirers; but, to the generation that followed, her novels necessarily appeared old-fashioned: the very language belonged to the past century. Macaulay's enthusiasm, when he likened her to Shakespeare and Molière, was premature, and perhaps unguarded. Other writers, from Southey to Henry James, have been content to cherish a private appreciation of her art. General approbation grew, however, until (in 1910) E. V. Lucas could call her "an English classic." Since A. C. Bradley recalled critical attention to the peculiar quality of her genius (in 1911), her standing as a novelist has not been seriously challenged; detraction has fastened on her character, alleging that her apprehension was dull, her temperament cold, her mind and heart narrow —despite the contrary witness of biographical accounts based on personal recollection or family tradition. Appreciation of the moral sensibility and seriousness discoverable in her novels has lately advanced, at some cost to the enjoyment of her wit. Happily, at the time when her idiom began to require occasional interpretation, she obtained the devoted service of the editor she deserved, alike for the novels, the extant letters and fragments of her work and play which survive in manuscript.

Bibliography.—All of Jane Austen's extant writings have been edited by R. W. Chapman: the six novels, 5 vol., 3rd ed. (1933); the letters, 2 vol., 2nd ed. (1952); *Lady Susan* and *Sanditon* (1925); *The Watsons* (1927); and two of the three notebooks containing fair copies of her *Juvenilia* (1932 and 1951)—all three now appearing with the rest of the fragmentary pieces as *Minor Works* (1954). The primary biographies are: J. E. Austen-Leigh, *A Memoir of Jane Austen* (1870), and the authoritative work by W. and R. A. Austen-Leigh, *Jane Austen, Her Life and Letters: a Family Record* (1913); but biographical accounts derived directly or indirectly from personal recollection include: Lord Brabourne's preface to his edition of some of the *Letters of Jane Austen* (1884); Constance Hill, *Jane Austen, Her Homes and Her Friends* (1902); J. H. and E. Hubback, *Jane Austen's Sailor Brothers* (1906); M. A. Austen-Leigh, *Personal Aspects of Jane Austen* (1920). Biography and criticism in varying proportions compose: C. L. Thomson, *Jane Austen: a Survey* (1929); Elizabeth Jenkins, *Jane Austen: a Biography* (1938); Mary Lascelles, *Jane Austen and Her Art* (1939; rev. 1959); R. W. Chapman, *Jane Austen: Facts and Problems* (1948). Among reviews, lectures and other brief critical pieces, these are notable: Sir Walter Scott's review of *Emma* for the *Quarterly Review 1815* (1816); Richard Whately's review of *Northanger Abbey* and *Persuasion*, for the *Quarterly Review* (1821); A. C. Bradley in *Essays and Studies by Members of the English Association* (1911); Virginia Woolf in *The Common Reader* (1925); Lord David Cecil, *Jane Austen*, his Leslie Stephen Lecture (1935); E. M. Forster in *Abinger Harvest* (1936). *See* G. L. Keynes, *Jane Austen: a Bibliography* (1929); R. W. Chapman, *Jane Austen: a Critical Bibliography*, 2nd ed. (1955).

AUSTERLITZ, BATTLE OF, a French victory over the Russians and Austrians, won on Dec. 2, 1805, near Austerlitz (Czech, Slavkov) in Moravia. Napoleon's masterpiece, it dramatically reversed his militarily and politically dangerous situation, secured his imperial regime and gave him the initiative in Europe with which he was soon to obtain his greatest triumphs (*see* Napoleon I; Napoleonic Wars). The Austrians, 80,000 strong, had invaded Bavaria on Sept. 8, 1805, without waiting for the first of the two Russian armies marching to their support,

although Napoleon was bringing an excellent army twice their size against them. By Oct. 20 about 49,000 Austrians had surrendered at Ulm; only one division of their invading force escaped to join the 30,000 Russians under M. I. Kutuzov, who had reached the Inn river and who now retired before Napoleon's superior numbers. The French entered Vienna on Nov. 13 and crossed the Danube to pursue the Russians into Moravia. Napoleon's position soon became critical, demanding an early victory if he was not to be overwhelmed, for not only had the second Russian army joined Kutuzov and the Austrians already before him, who now turned about at Olmütz (Olomouc), 90,000 strong, but also the French right flank was menaced by the approach of the Austrian archduke Charles (recalled from Italy) with 80,000 men. Prompt success was necessary also to avert Prussian intervention. Napoleon halted his extended advance at Brünn (Brno). His 100,000 men were disposed over a distance of 90 mi. to observe the opposing forces while he waited for the chance to concentrate against either to fight a decisive battle. Welcoming Kutuzov's rather ill-advised advance in the last days of November, Napoleon encouraged him to seek battle by retiring a short distance to adopt a position 7 mi. S.E. of Brünn, where he succeeded in quickly and secretly concentrating as many as 73,000 men behind the Goldbach stream. His tactics were of a piece with his masterly strategy, for he left his right unstrengthened to tempt the Russian forces to strike at his thus virtually uncovered communications with Vienna. As he had foreseen, the Russian army, 87,000 strong deployed along an already overlong front across the valley, fell into the trap, descending the Pratzen plateau in the centre of their position early on Dec. 2 to turn the French right. Napoleon's left and right wings held fast as the heavy French forces sent to the plateau pierced the weakened allied centre, where determined Russian counterattacks failed to prevent them from exploiting their dominating advantage. The allies' left wing was completely routed in the ensuing debacle, and their army's losses increased in the vigorous pursuit that followed. They lost about 26,000 men and 180 guns, the French between 7,000 and 8,000 men. The Austrian emperor Francis I signed an armistice on Dec. 6, and the broken Russian army was withdrawn under a truce. (J. H. N.)

AUSTIN, ALFRED (1835–1913), English poet who succeeded Tennyson as laureate, was born in or near Leeds, May 30, 1835. Educated at Stonyhurst, Oscott and London university, he was called to the bar in 1857, but began to write (*Randolph*, 1854; recast as *Leszko the Bastard: a Tale of Polish Grief*, 1877) and also entered politics, standing unsuccessfully as a Conservative, and becoming leader writer for the *Standard* (1866–96) and editor of the *National Review* (with W. J. Courthope, 1883–87; alone, 1887–95). His appointment to the laureateship, in 1896, was attributed to his flattery of Lord Salisbury. His inept official verses, beginning with a fulsome ode on the Jameson raid, his lack of judgment (he criticized the leading poets as "essentially childish," and regarded attacks on his own work as equal to those made on Byron and Keats), his snobbishness, and his genius for writing bad verse —of which his lines on the illness of the prince of Wales

> Across the wires the electric message came
> 'He is no better, he is much the same'

are a famous example—made him a critical butt. Swinburne called him "the Austin creature." *Punch* ran a series on "sickly, broken-winded Austin" and the *Athenaeum*, announcing his death (at Ashford, Kent, June 2, 1913) commented that the laureateship, virtually vacant since Tennyson's death, was now actually so.

Yet there is good in Austin. He could write simply in praise of the English and Tuscan countryside, and his prose "garden diaries," his only popular successes, have charm. Even at his most jingoistic, he might claim to represent popular feeling, although he lacked the touch to transmute it into poetry.

Of his voluminous writings, the following are typical: *The Season: a Satire* (1861); *The Human Tragedy* (1862; expanded 1876, 1880, 1891); *England's Darling* (Alfred the Great; 1896); *Soliloquies in Song* (1882); *Sacred and Profane Love* (1908); *The End and Limits of Objective Poetry* (1887); and *The Garden That I Love* (1894).

See Norton B. Crowell, *Alfred Austin: Victorian* (1953); *Times Literary Supplement* (Nov. 13, 1953).

AUSTIN, FREDERIC (1872–1952), English singer and composer, best known for his arrangement of *The Beggar's Opera*, by John Gay (*q.v.*), for its first modern production, by Nigel Playfair, at the Lyric theatre, Hammersmith (1920–23). Born in London, March 30, 1872, of a musical family, he studied singing while teaching harmony at Liverpool and made his first London appearance in 1902. From 1908 he took leading baritone roles at Covent Garden. As a composer, Austin was interested in modern music, and sang in the first performance of Delius' *Sea Drift* (1908) and in Rutland Boughton's operas at Glastonbury. He also became well known in Germany, the Netherlands and Denmark. His editing of the music of *The Beggar's Opera* showed his experience as a singer and his sound musical training in its realization, in a modern harmonization, of 18th-century style. He himself at first took the part of Peachum. In 1923 he arranged the sequel, *Polly*, and in 1924 he became artistic director of the British National Opera company. His compositions include songs, church music, chamber works and incidental music to plays. He died in London, April 10, 1952.

AUSTIN, HERBERT AUSTIN, 1st Baron (1866–1941), of Longbridge, the founder of the Austin Motor company and its first chairman, was born on Nov. 8, 1866, at Little Missenden, Buckinghamshire. He spent much of his early life in Australia, becoming manager and later director of the Wolseley Sheep-Shearing Machine company, the manufacture of whose machines he controlled in England. In 1895 he designed the first Wolseley car—a three-wheeler—and in 1900 drove the first Wolseley four-wheeled car, which he also designed, through the Thousand Miles trial. Austin began his own production of motor cars at Longbridge works, Birmingham, in 1906 and founded the Austin Motor company the same year. Later, this company's lightweight Austin Seven model greatly influenced British and European light car design. During 1951–52 the company was merged with Morris Motors Ltd. to form the British Motor corporation.

In 1917 Austin received a knighthood and from 1919 to 1924 was member of parliament as a Conservative for King's Norton. In 1936 he was created a baron. The title became extinct on his death near Bromsgrove, Worcestershire, on May 23, 1941. (St. J. C. N.)

AUSTIN, JOHN (1790–1859), the most influential English writer on jurisprudence after Jeremy Bentham, was born on March 3, 1790. After five years in the army he began to study law in 1812 and from 1818 to 1825 practised unsuccessfully at the chancery bar. His powers of rigorous analysis and his uncompromising intellectual honesty deeply impressed his contemporaries and in 1826 when the University of London was founded he was appointed its first professor of jurisprudence. He spent the next two years in Germany studying Roman law and the German civilians whose ideas of classification and systematic analysis exerted an influence on him second only to that of Bentham. Both Austin and his talented wife Sarah were ardent Utilitarians, intimate friends of Bentham and of James and John Stuart Mill and much concerned with legal reform. Austin's first lectures in 1828 were attended by many distinguished men but he failed to attract students.

He resigned his chair in 1832 in bitter disappointment and after delivering in 1834 a shorter but equally unsuccessful version of his lectures he abandoned the teaching of jurisprudence. He was appointed in 1833 to the Criminal Law commission, but resigned in frustration after signing its first two reports. In 1836 he was appointed a commissioner on the affairs of Malta. The Austins then lived abroad, chiefly in Paris, until 1848 when they settled in Weybridge, Surrey, where Austin died in Dec. 1859. Bouts of nervous illness and self-distrust prevented Austin from fully deploying his great powers; his life, as his widow wrote, was one of "unbroken disappointment and failure" in ironic contrast with his posthumous fame and influence.

Austin's best-known work is *The Province of Jurisprudence Determined*, a version of part of his lectures published in 1832. Here, in order to clarify the distinction between law and morality blurred by doctrines of Natural Law, he elaborated his definition

of law as a species of command. Commands are expressions of desire that another shall do or forbear from some act, accompanied by a threat of punishment (the "sanction") for disobedience. Commands are laws "simply and properly so-called" when they are general and are "set" by the "sovereign"; *i.e.*, the person or persons to whom the bulk of a society renders habitual obedience and who renders no such obedience to others. This is the mark distinguishing "positive law" both from the fundamental principles of morality which are the "law of God" and from "positive morality" or man-made rules of conduct, such as etiquette, conventional morality and international law, which do not emanate from a sovereign. *The Province* also contains a version of Utilitarianism in which "utility" is regarded as the index of God's commands and the test of the moral quality of general rules of conduct rather than of particular actions.

Austin viewed the doctrines of *The Province* as "merely prefatory" to the study which he termed "general jurisprudence." This was the exposition and analysis of the fundamental notions forming the framework of all mature legal systems. Hence he devoted the main part of his lectures (published only in 1863) to a detailed analysis of such "pervading notions" as those of right, duty, persons, status, delict and sources of law. This general or analytical jurisprudence was distinguished from the criticism of legal institutions which Austin called the "science of legislation"; he thought both were important parts of legal education.

Austin's work has exerted a profound influence on English jurisprudence and legal education. A long succession of English writers have echoed or elaborated his doctrines or, when opposing them, have accepted his conception of the analysis of legal concepts as the central concern of jurisprudence. In the United States jurists such as J. C. Gray and O. W. Holmes welcomed his bold distinction between law and morality as a major clarification.

When the reaction came with the turn of the century it was severe. The command theory has been condemned as a misidentification of all law with the product of legislation and a distortion of many types of legal rule. The severance of a purely analytical jurisprudence from moral criticism of law has been criticized as sterile verbalism obscuring the social function of law and the judicial process. Some critics consider that the doctrine of sovereignty confuses the ideas of legal authority and political power; others have even held "legal positivism" responsible for subservience to state tyranny or absolutism.

Some of these criticisms are well founded, but in spite of its mistakes Austin's work is of permanent value. The rigour and clarity of his analysis have demonstrated the complexity of many important legal and political concepts and the perennial need for just such an analytical study as he proposed; and repeated efforts to show precisely where his simple distinctions between law and morality are wrong have increased the understanding of both.

See J. S. Mill's review of the *Lectures on Jurisprudence* reprinted in *Dissertations and Discussions*, vol. iii; R. A. Eastwood and G. W. Keeton, *Austinian Theories of Law and Sovereignty* (1929).

(H. L. A. H.)

AUSTIN, MARY (née HUNTER) (1868–1934), U.S. novelist and essayist, is best remembered for her works on Indian cultures. She was born at Carlinville, Ill., on Sept. 9, 1868. She graduated at Blackburn college there in 1888, taught for a time, and then moved to California, where she became the friend and chronicler of the nearby Indian tribes. Her first book, *The Land of Little Rain* (1903), a description of desert life in the west, won her immediate fame, and was followed by *The Basket Woman* (1904) and *Lost Borders* (1909), both volumes of short stories, and *The Arrow Maker*, a play (1911).

After 1905 Mrs. Austin lived in Carmel, Calif., abroad and in New York city before settling at Santa Fe, N.M., in 1924 where she died on Aug. 13, 1934. She became a prolific writer, publishing 32 volumes and about 200 articles in her lifetime, including such "problem" novels as *A Woman of Genius* (1912) and essays about socialism, feminism and the various social problems she was concerned with through her association with the group of artists and writers revolving about Mabel Dodge in New York. Except for her nature essays, lively in observation and transcendental in tone, her work is heavily didactic and primarily of historical interest.

BIBLIOGRAPHY.—*Earth Horizon* (1932), an autobiography; H. M. Doyle, *Mary Austin, Woman of Genius* (1939); and estimates in H. C. Tracy, *American Naturists* (1930), and Van Wyck Brooks, *The Confident Years: 1800–1915* (1952).

AUSTIN, STEPHEN FULLER (1793–1836), an American frontier colonizer and founder of the principal settlements of English-speaking people in Texas during the 1820s, while that territory was still a part of Mexico. He was born Nov. 3, 1793, in Austinville, Va., the oldest son of Maria Brown, of Quaker descent, and Moses Austin (1761–1821), who had himself inaugurated the project for the colonization of Texas during the last year or two of his life. Moses was caught in the financial panic of 1819 and left the lead mining region of southeast Missouri, where he had settled, for Texas. There he obtained a grant of land for colonization purposes (Jan. 1821) but died six months later, leaving his son to carry out the enterprise. Stephen F. Austin had been educated at Bacon academy, Colchester, Conn., and at Transylvania university, Lexington, Ky., and had served in the territorial legislature of Missouri from 1814 to 1819, when the slavery question was raised to a high pitch over the Tallmadge proposal to exclude slavery upon the admission of Missouri as a state. Involved in his father's business misfortunes, he joined a general migration into the new territory of Arkansas and opened a farm at Long Prairie, on the Red river, as a step toward Texas; but proceeding to New Orleans he learned that the approaches to Texas from that city were better. There he began the study of law and assisted in editing the *Louisiana Advertiser*, until the middle of July 1821, when, with all the vigour of a young man, he entered Texas and, during the following winter, planned a substantial settlement near the coast between the Brazos and the Colorado rivers. Meanwhile a successful revolution had occurred in Mexico and it became necessary for him to go to Mexico City to secure the confirmation of his grants. For some years thereafter he was one of the main factors in the struggle between two civilizations for the possession of Texas.

In the interest of the slaveholding element of Anglo-Americans, Austin successfully defeated the efforts of Mexican statesmen, who were supported by British agents and diplomats, to keep Negro slavery out of Texas. In 1833, when he failed to induce the Mexican government to make Texas a separate state in the confederation so that the American settlers might have the liberty and self-government they considered indispensable, he wrote home recommending the organization of a state without waiting for the consent of the Mexican congress, and was thrown into prison. He was released in 1835, the Texas revolution followed, and Austin secured help from people in the United States. In the end he found himself and his colonies practically submerged by the flood of adventurers and immigrants, and the revolution was successful. Sam Houston (*q.v.*) defeated him in a campaign for the presidency, and Austin died on Dec. 27, 1836, while serving as secretary of state. As a colonizer on an advancing frontier where there was a contest between two civilizations and where one had to restrain his own followers and conciliate the defense, Austin's work was of a high order, and it constitutes his chief title to fame.

AUSTIN, a city of Minnesota, U.S., 90 mi. S. of Minneapolis and St. Paul, on the Red Cedar river; seat of Mower county. The first settler's cabin on the site of Austin was erected in 1853. Austin was platted in 1856 and chartered as a city in 1873. The trading centre of a rich corn and hog-raising area, the city's major industry is meat packing. Other industries include railroad shops and a plant manufacturing corrugated paper. Austin junior college, founded in 1940, is located there.

For comparative population figures *see* table in MINNESOTA: *Population*. (H. T. H.)

AUSTIN, the capital city of Texas, U.S., and seat of Travis county. It lies in a valley near the centre of the state, on both banks of a sprawling meander of the Colorado river, and is sur-

rounded by timbered hills and ravines. The business district is embraced within the bend of the river and bisected by Congress avenue, which dips into the valley, crosses the river and ascends directly to the pink granite capitol building, beyond which and higher rises the 27-story bell tower of the University of Texas.

The site was first settled in 1835. In 1838 Mirabeau B. Lamar, who became the president of the Republic of Texas, stopped there on a hunting trip, and in 1839 it was selected for the capital and named for Stephen F. Austin (*q.v.*). When the Mexicans invaded Texas in 1842, Sam Houston, then president of the republic, moved the capital to Houston. The citizens of Austin, fearing that Houston would become the permanent capital, retrieved the archives from a company of Texas rangers sent to carry them to Houston, and the incident became known as the archive war. By 1845 the capital was secure again in Austin.

During the years of the republic various diplomats lived in the city, and the old French embassy is maintained as a historic site. The governor's mansion (1853), a showpiece of southern colonial architecture, overlooks the capitol and its lawns. The mansion's east façade was decorated with fluted Greek pillars with Ionic caps, which were shaped from pine logs hauled from nearby Bastrop by slave labour. The residents of Travis county voted against secession from the union, 704 to 450, but they sent many young men to defend the Confederacy.

The original capitol, a one-story frame building, was protected from Indians as late as 1845 by an eight-foot stockade. A Chicago syndicate built the new capitol, second in size to the national capitol in Washington, D.C., in 1883–88 in return for 3,000,000 ac. of public land in the Texas Panhandle. In 1894 metal light towers, 165 ft. high, were erected, and 27 of them still suffuse the Austin evenings with their mercury vapour glow.

Of the city's labour force only 1 in 13 persons is employed in the 250 manufactories, while 1 in 5 works for the state, 1 in 5 in services and 1 in 6 in the retail trades. Apart from services and trade, the working population of the city is employed in construction, real estate, insurance, finance, printing, agriculture, furniture, and stone, clay and glass industries.

Austin, the political city of the state, is also an educational, cultural and artistic centre, the home of many of the state's artists and writers. William Brann launched his *Iconoclast* there. O. Henry (*q.v.*) bought him out and published his humorous weekly, *The Rolling Stone*. Elisabet Ney, the sculptress, worked there in her castlelike home and studio.

The city maintains a symphony orchestra, a civic theatre and an art gallery. A library was first opened in 1873 "to elevate the tone of our society"; after the mid-20th century the city library contained 120,000 volumes and a free film and record service.

The University of Texas, founded in 1881, has its main campus at Austin. Its library, with about 1,500,000 volumes, includes the following collections: Texas collection, Latin-American collection (founded on Garcia library), archives, newspaper collection and the rare book collection, including priceless first English editions in the Wrenn and Stark libraries. Several other institutions of higher education are located in Austin: St. Edward's university, a Catholic men's school founded in 1885; Concordia college, a Lutheran junior college founded in 1926; Huston-Tillotson college, a Negro institution founded in 1876; the Austin Presbyterian Theological seminary, founded in 1902; and the Southwest Episcopal seminary, founded in 1951.

Several state public assistance institutions, the state museum and state library are located in Austin. Bergstrom air force base is near the city.

Hydroelectric power dams built by the Lower Colorado River authority form Lake Austin, Lake Travis, Granite Shoals lake, Marble Falls lake, Inks lake and Buchanan lake. They form a chain of lakes descending from 60 mi. N. to the city, providing the region with an excellent recreational area.

Pop. (1960) city, 186,545; standard metropolitan statistical area (Travis county), 212,136. For comparative population figures *see* table in TEXAS: *Population*. (R. E. DU.)

AUSTRALASIA, a term that has never had a precise definition and that was originally employed to denote land believed to exist south of Asia. In its widest sense it has been taken to include besides Australia (with Tasmania) and New Zealand, the Malay archipelago and the Philippines; Melanesia (New Guinea and the island groups lying east and southeast of it as far as and including New Caledonia and the Fiji Islands); Micronesia (the island groups extending from Pelew Island and the Ladrones east-southeast to include the Marshall and Gilbert groups); Polynesia (the scattered groups of islands extending eastward from the above groups to about longitude 130° E.). But the Hawaiian Islands, and even Antarctica, have been included under the heading "Australasia." The word is falling out of use although it is still employed by Australian companies and societies operating beyond the Australian continent. *See* also OCEANIA.

AUSTRALIA, COMMONWEALTH OF, occupies the smallest, most arid and least densely populated of the continents. It is a self-governing member of the Commonwealth of Nations (*q.v.*) and its capital city is Canberra. With an area of 2,971,081 sq.mi. (mainland alone, 2,944.866 sq.mi.), it is about the size of conterminous United States and more than three-fourths the size of Europe. (Tasmania and other adjacent islands are included in the above area, but not Papua or the trust territories.) Australia's maximum east-west extension is about 2,400 mi. and its north-south distance about 1,970 mi. With a coast of 12,210 mi., giving a proportion of 1 mi. of coast to 244 sq.mi. of land surface, Australia is a markedly compact land mass. This fact, in conjunction with its shape and latitudinal position, influences the climate and hence the general geographical character of the country. It lies wholly in the southern hemisphere between longitude 113° 9′ and 153° 39′ E. and latitude 10° 41′ and 43° 39′ S. (mainland, 39° 8′ S.). It derives its name from the Latin *terra australis* or "southern land."

The isolation of Australia is one of the most significant factors in its geography. Only in the northwest does it face the outposts of Asian civilization at no great distance (Darwin-Timor, about 400 mi.); and the northern area is in general difficult country. Hence contacts with the islands to the north, though probably intermittent throughout historic time, did not become significant until the mid-19th century. On all other sides Australia is surrounded by wide expanses of ocean. Nevertheless, it is the largest land mass, with the largest and most technically advanced population, within the Pacific, and indeed it may be said to dominate the whole of the southwest of that ocean.

Australia, like New Zealand, is remote from the British Isles but is linked to the mother country by two sea routes, one through the Suez canal and the other through the Panama canal. The distance by the London-Suez-Colombo-Fremantle route is 9,537 nautical miles; by the Liverpool-Panama-Sydney route it is 12,222 nautical miles.

This article contains the following sections:

I. PHYSICAL GEOGRAPHY

A. GEOLOGY

Australia, like all other continents, consists of a core or shield of ancient Pre-Cambrian rocks flanked and, in some places, covered by younger rocks. In the case of Australia this shield of ancient rocks, ranging from 3,000,000,000 to 600,000,000 years old is very large and underlies most of the western and central parts of the continent, the eastern part of the continent is an accretion to the shield and has been built up within the last 600,000,000 years

The continent may be divided into the three structural units shown in fig. 1. The Pre-Cambrian shield established the framework of the western half of the continent by the end of Pre-Cambrian time; the Tasman geosyncline built up the eastern states of the continent in Paleozoic time, 600,000,000 to 200,000,000 years ago; the east central depression became evident about 200,000,000 years ago, in Mesozoic time, and gave rise to an irregular corridor of sea and lakes between the fold mountains of the Tasman geosyncline in the east and the Pre-Cambrian shield in the west.

Although admittedly an oversimplification, the growth of the continent seems to have followed a general pattern of consolidation progressing eastward and northeastward from the southern portion of Western Australia. The Paleozoic fold belt, now comparatively stable, marks the present eastern limit of the continent, but farther north and east lie the less stable Mesozoic and Tertiary fold belts trending through New Guinea and island arcs to New Zealand.

Pre-Cambrian.—Outcrops of Pre-Cambrian rocks are widespread in Western Australia, South Australia and the Northern Territory. This great area of Pre-Cambrian rocks is referred to as the Australia Pre-Cambrian shield; it extends into western Queensland and western New South Wales. Areas between outcrops of these old rocks are occupied by a thin cover of younger sedimentary rocks, sand or alluvium or by thicker sediments deposited in basin-like depressions in the Pre-Cambrian basement. The names of the basins that are of particular interest in the search for oil and water appear on fig. 1. Isolated outcrops or "windows" of Pre-Cambrian basement rocks appear in the Tasman geosyncline in northeast Queensland and in Tasmania. The history of the Pre-Cambrian period, which accounts for about five-sixths of the whole of geological time, is essentially that of the growth and consolidation of this shield which has been fairly stable since the end of Pre-Cambrian time.

Archean.—The rocks of this era, from more than 3,000,000,000 to perhaps 2,000,000,000 years ago, include some recognizable but altered sedimentary rocks, lavas and many other types of igneous rocks including many granites now altered to gneisses. The most representative rock types are schists and gneisses derived by metamorphism from original sedimentary or igneous rocks. Slate, quartzite and "greenstones" (altered basic lava flows) are prominent in Archean sequences in Western Australia. Rocks considered to be definitely of Archean age are everywhere severely folded and compressed.

Proterozoic.—The record of Proterozoic rocks is more understandable than that of earlier times: the degree of metamorphism is less and deposition of normal sediments in troughs and basins by recognized geological processes can be more easily traced. Lower Proterozoic rocks are at present best known in the Northern Territory and western Queensland, but rocks of the same general age are probably represented in some areas of South Australia and Western Australia. In most places these rocks occur in fairly well-defined belts and include many little-altered sediments like sandstone, graywacke, shale and limestone deposited in geosynclines; but some have been metamorphosed and resemble Archean rocks. The rocks have been folded to varying degrees but, in general, are much less deformed than Archean rocks. Many Proterozoic granites intrude Lower Proterozoic and Archean rocks; these, for the most part, show little alteration.

Upper Proterozoic rocks provide, in general, a marked contrast with the older Pre-Cambrian; they consist mainly of unaltered sediments and lavas deposited in broad basins within the older rocks. They have been little folded, are not intruded by granites except in the Adelaide geosyncline and, in many places, rest almost horizontally on steeply inclined older beds. This applies particularly to Western Australia and to the Northern Territory where consolidation of the shield was well advanced in Upper Proterozoic time; local severe folding of Upper Proterozoic rocks occurs in a few places, notably at Yampi sound in the far northwest.

A major fold belt of Upper Proterozoic rocks is the Adelaide geosyncline in South Australia where an immense pile of sediments was deposited in a trough which existed through Upper Proterozoic

FIG. 1.—GEOLOGICAL FORMATIONS IN AUSTRALIA SHOWING SEDIMENTARY BASINS

and part of Cambrian time. The Upper Proterozoic sediments constituting the Adelaide system consist mainly of sandstone, graywacke, dolomite and red beds; the system has been divided into four series of which the second youngest includes sediments derived from glaciation of the land surface in Late Proterozoic time.

The sequence of Upper Proterozoic rocks in Western Australia and the Northern Territory can be broadly correlated with the Adelaide system although they cannot yet be split into four series. However, in places the Upper Proterozoic can be divided into two; the lower sequence consists mainly of sandstone with lava flows and some iron ore beds (red beds); the upper includes sandstone, dolomite, shale and red beds with glacial sediments which may be broadly correlated with those of the Adelaide system.

Economic Geology.—In Australia, as in other parts of the world, the Pre-Cambrian shield provides the richest source of minerals. The greater part of Australia's total production of gold, lead, zinc, iron and uranium has been won from the shield, mainly from Archean and Lower Proterozoic rocks.

Upper Proterozoic rocks are largely unmineralized and have contributed much less than the older Pre-Cambrian; they provide some uranium in the Northern Territory but their main contribution has been from the iron-bearing beds at Yampi sound in northwestern Western Australia and in the Constance range in northwestern Queensland.

Paleozoic.—Events in the Paleozoic era took place in two different environments. A broad meridional mobile belt—the Tasman geosyncline—was initiated in eastern Australia where sedimentation and recurrent folding and igneous intrusion persisted throughout Paleozoic time; contemporaneously, the more stable Pre-Cambrian shield, although for the most part a land area, developed depressions in which sediments were deposited. These depressions formed seaways across the shield in Lower Paleozoic time but were restricted to four major embayments along the western coast in the Upper Paleozoic—the sites of the Bonaparte gulf and the Canning, Carnarvon and Perth basins. Sedimentation continued into Mesozoic time in all basins and persisted into the Tertiary in the Carnarvon and Perth basins.

The relative stability of the Pre-Cambrian shield in contrast with the Tasman geosyncline, first apparent in the Early Paleozoic, persisted as a basic feature of the structural evolution of the continent. The contrast in environment is reflected in both type of sedimentation and structural history; thick, folded sequences of graywackes are typical of the Tasman in contrast with thinner,

little-folded successions of sandstone, limestone and shale in the basins on the shield.

Lower Paleozoic (*Cambrian, Ordovician and Silurian Periods*).—Sedimentation began in the Tasman geosyncline in the Cambrian period. The oldest-known sediments there are fossiliferous Middle Cambrian graywackes and volcanics in Victoria and Tasmania where submarine volcanic activity was intense, but unfossiliferous metamorphic and volcanic rocks in Tasmania and near Brisbane may represent Lower Cambrian sedimentation.

The record of Ordovician and Silurian times is less obscure and presents a general picture of a geosyncline with widespread sedimentation but not entirely covered by sea at any one time; details emerging in many places indicate that ridges and islands existed within the geosyncline and that sedimentation probably took place in smaller troughs and basins. At different times and places supplies of sediments apparently came from the west, from island ridges and from land that formed the eastern boundary of the geosyncline, now submerged beneath the Tasman sea.

Sedimentation was interrupted from time to time and rocks were followed by orogenies (episodes of structural deformation) beginning in Tasmania about the end of Cambrian time (Tyennan orogeny). Succeeding, fairly widespread orogenies accompanied by granite emplacement occurred about the end of Ordovician time (Benambean or Benambran orogeny) and toward the close of the Silurian (Bowning orogeny). None of these orogenies affected all parts of the geosyncline but resulted in a changing pattern of sedimentation, folded uplift and erosion.

Ordovician rocks, mainly trough deposits of the graywacke suite, were laid down in many areas along the full length of the geosyncline. Similar rocks were deposited in the Silurian, but calcareous rocks including limestone became prominent, particularly in northern Queensland and southern New South Wales, and tremendous outpourings of acid lavas dominated Middle and Upper Silurian sequences in the latter area.

On the Pre-Cambrian shield, the Adelaide geosyncline was filled up mainly with sandstone, dolomite, limestone and shale in the Lower and Middle Cambrian. A seaway, in which similar sediments were deposited, may have developed from this geosyncline northward to central Australia and certainly extended from there to the northwestern coast in Lower and Middle Cambrian time. Toward the end of Middle Cambrian time, South Australia became dry land and the seaway possibly trended eastward from central Australia to join the Tasman sea. This pattern continued throughout the Ordovician with further sedimentation in the Amadeus basin in central Australia; but the seaway trended west rather than northwest from central Australia reaching the northwest coast of the continent through the Canning basin. A southerly arm probably flooded the Officer basin. The southwestern coast of the continent was submerged to initiate the Carnarvon and Perth basins, certainly in the Silurian and possibly in the Ordovician. With the exception of these two basins, the entire shield consisted of dry land in the Silurian. Sedimentation in the Adelaide geosyncline and in the Amadeus and Officer basins in central Australia had finished, but the coastal basins had been founded in embayments in the shield and had received further sedimentation in Upper Paleozoic and later time.

Upper Paleozoic (*Devonian, Carboniferous and Permian Periods*).—The gradual process of consolidation of the Tasman geosyncline can be clearly seen in events taking place in Devonian time; in fact, much of Tasmania, Victoria and parts of New South Wales and Queensland were essentially stabilized by one or both of the last two grand orogenies in these areas which took place about mid-Devonian (Tabberabberan orogeny) and in Late Devonian or Carboniferous time (Kanimblan orogeny). Granites accompanied these two orogenies.

Deposition occurred in troughs in many areas in Lower and Middle Devonian time, particularly in central Victoria and in northeastern New South Wales and eastern Queensland, but the onset of the Tabberabberan orogeny radically changed the picture. Sediments were folded in northeastern Queensland, central and southern New South Wales, Victoria and Tasmania; northeastern New South Wales and eastern Queensland (the New England trough) were apparently little affected by these movements [illegible] sedimentation continued.

Uplifts following this orogeny were short-lived and soon most of the geosyncline was again under water in the Upper Devonian. There was, however, a change in the environment and in the type of sedimentation in Upper Devonian time. Although trough deposition continued in eastern New South Wales and was revived in a few localities elsewhere, the Upper Devonian was a time of widespread deposition in shallow basins and in shallow seas that spread across the geosyncline. Volcanic activity was prominent only in southeastern New South Wales and in central Victoria; typical sediments were sandstone, shale and red beds. The same pattern continued into Early Carboniferous.

The Kanimblan orogeny, the last of the grand orogenies to have widespread effects throughout the geosyncline, interrupted sedimentation except in the New England trough. The movement raised much of the geosyncline well above sea level and the Upper Carboniferous sea was restricted to the eastern margin of the continent from Cape York peninsula to 100 mi. N.E. of Sydney. Both marine and terrestrial sediments were laid down in Queensland and New South Wales. Upper Carboniferous deposits in Queensland include lava flows and marine sandstone, shale and limestone; and, while, in northeastern New South Wales, mudstone, chert and lava flows continued to be laid down in the New England trough, thousands of feet of lava accumulated along its southwestern margin about 100 mi. N.E. of Sydney. The lavas are overlain by glacial deposits with plant fossils; these, in turn, pass upward into marine and terrestrial sediments, including Coal Measures, of definite Permian Age.

The Permian period is noteworthy for two events: the second widespread glaciation of the continent and the deposition of Australia's major Coal Measures. There is evidence of two stages of glaciation, a severe glaciation in the Lower Permian (apparently starting in Late Carboniferous time in eastern Australia) and a milder glaciation later in Permian time. The Permian seas inundated mainly the eastern seaboard of the continent and the western Australian basins, but many low-lying areas within the continent received a mantle of terrestrial sediments mainly derived from glaciated mountain ranges.

The Tasman geosyncline was now so far consolidated that earth movements produced broad basins rather than abrupt troughs and apart from the filling of the New England trough, sedimentation in the Permian took place in basins everywhere. Along the western margin of the Permian sea in eastern Australia and in [illegible] of the Perth basin in Western Australia, lay great swamps choked with vegetation from which developed, by subsequent compaction, the major Coal Measures of the continent. The great Bowen basin in Queensland and the Sydney basin in New South Wales originated in Permian or Late Carboniferous time and received great thicknesses of sandstone, shale, limestone, glacial sediments and coal seams; in places volcanic rocks were poured out.

Toward the end of Permian time the Hunter-Bowen orogeny took place mainly along the present eastern seaboard; this folded and uplifted Permian and older sediments in the New England trough and in eastern and northeastern Queensland; granites were emplaced in the same areas but the orogeny had little effect farther west and south.

The pattern of sedimentation established in Lower Paleozoic time in the sedimentary basins along the western margin of the shield continued throughout the Upper Paleozoic. By the Middle Devonian the ancestral Indian ocean again flooded these basins and in the Fitzroy basin sedimentation was dominated by reefs which fringed its northeastern margin.

In the Lower Carboniferous, sandstone, limestone and other calcareous sediments were deposited in all of these basins but, except for an area in the Fitzroy basin, the embayments were apparently raised above sea level in Upper Carboniferous time. In Permian time much the same type of sedimentation took place in the Western Australian basins as in those near the eastern seaboard, but volcanism was absent and the only economic coal measures were laid down south of Perth. Deposits in the Carnarvon and Canning basins consisted of limestone, sandstone and

shale with glacial sediments prominent in the lower part of the Permian sequence. The Canning basin extended far to the southeast where marine sediments passed into terrestrial glacial deposits. Similar glacial deposits found in South Australia and remnants found in the Northern Territory complete the evidence for widespread glaciation in Permian time.

Economic Geology.—Mineralization of Cambrian Age has been recognized only in the Adelaide geosyncline, but gold, silver, lead and copper were introduced by Silurian granites in places within the Tasman geosyncline. Lower Paleozoic sedimentation of the shield began the sequences within the sedimentary basins that have become sources of underground water and focal points in the search for oil.

Granites accompanying the Tabberabberan, Kanimblan and Hunter-Bowen orogenies were responsible for the introduction of the greater part of the gold, tin, copper and silver-lead deposits of eastern Australia. Apart from the metals, the principal economic interest lies in the vast reserves of bituminous coal, mainly in the Bowen and Sydney basins in eastern Australia. From a broader viewpoint, the initiation in Permian time, along the eastern coast of the continent, of sedimentary basins that were not subsequently subjected to severe folding or intrusion was the starting point of real prospects for oil in the Tasman geosyncline.

Mesozoic.—(*Triassic, Jurassic and Cretaceous Periods*).—In Mesozoic time (220,000,000–70,000,000 years ago) sedimentation in both eastern and western Australia took place in the basins but, whereas deposition followed the established pattern in the Western Australian basins, the relative instability of eastern Australia gave rise to new sedimentary basins.

In the Triassic in eastern Australia the belt running northward into southeast Queensland was at last uplifted, but sedimentation continued in the Bowen and Sydney basins until about the end of the period. From the Jurassic onward, the east central depression gradually dominated the scene and gave rise to a tremendous area of gradually subsiding lakes and swamps in Queensland and to smaller depressions or embayments in New South Wales and Victoria; thus were initiated the Carpentaria, Great Artesian, Murray, Otway and Gippsland basins. In these, fresh-water sediments, mainly sandstone with shale and coal seams in places, alternated with marine shale and calcareous sediments resulting from incursions of the sea. Sedimentation continued into the Tertiary period, particularly in the southern basins. In the Great Artesian basin the main marine incursion occurred in Lower Cretaceous time followed by gentle uplifts which returned the basin to an area of swamps and fresh-water lakes.

Events in eastern Australia in the Mesozoic can be recognized in the sedimentary record of the Western Australian basins; these were largely drained in the Upper Triassic but further sedimentation followed in the Jurassic and Lower Cretaceous when the basins were intermittent lakes barred from the sea for most of the time, with infrequent marine incursions from the west. Sandstone, siltstone and calcareous sediments, both marine and terrestrial, were the principal sediments laid down.

The pronounced sagging in the Early Cretaceous affected two other areas of the shield. The northern part of the Northern Territory foundered and a shallow sea, in which fine shaly sediments were laid down, spread from the Great Artesian basin northwestward to the Bonaparte gulf. Farther south a new basin (Eucla) was initiated in an embayment along the southern margin of the shield. Gentle uplifts toward the end of the Mesozoic drained these seas and the continent then extended southward to include Tasmania and northward to include part of New Guinea.

Some volcanic activity occurred in eastern Australia in the Mesozoic, notably in Queensland, but it was only a faint echo of the outbursts that occurred in the Paleozoic. Great dolomite sills were intruded in Tasmania and some granite was emplaced in eastern Queensland, associated with mild orogeny toward the end of the era (Maryborough orogeny).

Economic Geology.—Some minerals were introduced by granites in Queensland but of more importance were the occurrence of bituminous coal in Queensland, Victoria, Tasmania and South Australia, the deposition of the sandstone aquifers which store most of the underground water in the Great Artesian basin, and the laying down of additional source and reservoir rocks for oil in most of the sedimentary basins.

Cenozoic.—(*Tertiary and Quaternary Periods*).—The series of lakes in the east central depression persisted from Cretaceous into Tertiary time. Fresh-water sediments were deposited in parts of the Carpentaria and Great Artesian basins in the Lower Tertiary, and sedimentation, both marine and terrestrial, continued until about the end of Tertiary time in the Murray, Otway and Gippsland basins. Large swampy lakes developed in Victorian basins in Lower Tertiary time and, in the Gippsland basin, gave rise to the major brown coal deposits of Victoria.

Similar, but very much smaller, lakes and swamps developed in many parts of the continent, and sand, gravel and mud with lignite in places collected in the depressions; lake limestone is found particularly in northern and western Australia.

In the western part of the continent, the Canning basin received only scattered terrestrial sediments but marine calcareous sediments were laid down continuously from Cretaceous until Upper Tertiary time in part of the Carnarvon basin. The Perth and Eucla basins were again briefly flooded in the Lower Tertiary; the Eucla basin received extensive limestone deposits which now crop out over much of the Nullarbor plain and along the coast of the Great Australian bight.

In Lower Tertiary time there was a widespread but generally quiet outpouring of basaltic lava in eastern Australia (the older basalts). In many places lake deposits and valleys with flats and terraces of stream gravels were overridden by basalt; many of these have been preserved below the hard basalt and are termed "deep leads"; the stream gravels commonly contained alluvial gold or tin which has since been recovered in places.

Probably toward the end of the Lower Tertiary, widespread but gentle uplifts drained the sea from most of the coastal basins and the continent then extended slightly farther east and west than it does now and probably had land bridges southward to Tasmania and northward to Papua. The climate seems to have been temperate to tropical and pluvial throughout and gave rise to widespread laterization by deep leaching of the soils and underlying rock.

The approximate present shore line of the continent was established by further crustal movements in Early and Late Upper Tertiary time (Kosciusko uplift); faulting and downwarping, particularly in the earlier of these movements, severed Australia from New Guinea and Tasmania and established the Gulf of Carpentaria and Bass strait. More basalts poured out in eastern Australia (the newer basalts) toward the end of Upper Tertiary time; they were more restricted than those of the Lower Tertiary and occurred principally in central and western Victoria and in southeastern and northern Queensland.

The principal geological events in Quaternary time were the continuation of some of the crustal adjustments and of volcanic activity noted in the Late Tertiary, the Pleistocene Ice Age, and the fluctuation in sea level due to the waxing and waning of polar icecaps. Many features of the Australian seaboard are the results of these fluctuations; the sheltered deepwater harbours are drowned valleys, cut when sea level was hundreds of feet lower than it is now; and the coastal flats and lagoons are legacies of the fall in sea level during the Recent epoch. Deposits of the period include some volcanics, all of the unconsolidated sediments of the coastal plains, sand dunes and much of the cover of the alluviated inland plains.

Probably the most spectacular crustal movements in the Early Quaternary were the faulting and tilting of crustal blocks in central South Australia which produced the large depressions which occasionally flood and become vast lakes (Lake Eyre, etc.). The very gradual sinking of the continental shelf along the north Queensland coast began about this time and initiated the Great Barrier reef which continued to build upward as the shelf sank.

Economic Geology.—Of first importance are the extensive brown coal deposits of Victoria which provide most of the state's electric power and solid fuel. Deep leads have been prolific producers of alluvial gold and tin. Australia's bauxite deposits are

the result of Tertiary laterization. Commercial concentrations of rutile, zircon and ilmenite took place in beach sands, particularly along the coast of south Queensland and northern New South Wales in Quaternary time.

Tertiary sequences in the major sedimentary basins provide some additional source and reservoir beds for petroleum; but, in general, Tertiary sediments seem more important as cover rocks to confine oil within older sequences than as producers themselves.

B. Geomorphology

Many of the unique features of the continent, in particular its general flatness and lack of high mountains and the absence of permanent snow fields, glaciers and active volcanoes, stem largely from two salient features of its structural evolution—a tremendous area of Pre-Cambrian shield and the lack of fold mountains younger than Paleozoic. Mesozoic and younger strata, which form the greater part of the world's high fold mountain chains (like the European Alps), are generally subhorizontal and little disturbed on the Australian continent.

However, the surface of the continent still reflects, with muted relief, the three structural units of which it is composed. The greater part of the Pre-Cambrian shield is a plateau, little more than 1,000 ft. above sea level, whose monotonous, flat or gently rolling surface is the result of long periods of uninterrupted erosion and beveling across rocks and structures, extending back to Pre-Cambrian time in places. The surface is, in fact, a composite one consisting of remnants of land surfaces of many ages, some of which can be roughly dated as pre-Middle Cambrian, pre-Permian, pre-Cretaceous and Lower Tertiary. Widespread, mature laterization, which took place mainly on Lower Tertiary land surfaces, is the most useful time marker because it can be recognized in parts of the other two units. The monotony of the old peneplain is broken, in places, by isolated ranges, like the Harts range in central Australia, which generally mark the more mobile zones in the shield, or by mesas and plateaus.

The east central depression is represented by a wide, irregular belt of lowlands whose flat or gently undulating surface, developed in Cenozoic time, differs in origin from the peneplains of the shield; the surface of the lowlands reflects the softness and horizontal attitude of the underlying Mesozoic strata and has not been beveled across folded rocks. In the central and northern sections the Lower Tertiary lateritized surface can be traced, mainly on mesas standing above the more recent plains, but toward the southern end of the lowlands the sedimentation antedates the main period of laterization.

Eastward the lowlands gradually rise to the low mountain chain that borders the eastern coast of the continent, along the site of the Paleozoic fold mountains of the Tasman geosyncline. These mountains were worn down by the beginning of the Cenozoic era and since uplifted, by recurrent movements, as plateaus which streams have greatly modified. Remnants of a Cretaceous or Lower Tertiary peneplain can still be discerned in places as can the younger, lateritized Lower Tertiary surface that had considerable relief in some areas.

See also Precambrian Time and separate articles on the systems and periods of the Paleozoic, Mesozoic and Cenozoic eras as Cambrian System; Ordovician System; etc. (L. C. N.)

C. Physiography

Australia is in general the most archaic of the continents, the least affected by the Tertiary earth movements which built the Alps, the Himalayas, the American cordilleras and the Atlas mountains. The mountains of Australia are for the most part masses of rounded highlands, old fold mountains that have been worn down and then again uplifted, warped and faulted. There is no true alpine country; even around the highest mountain, Kosciusko (7,316 ft.), snow does not normally lie for the whole year, though in winter there are large areas of snow fields. The dominants of the Australian landscape are great plains and plateaus, and for the most part even the areas of rugged relief owe their ruggedness to the dissection of old plateaus.

The western two-thirds of Australia is formed essentially of a great shield of very ancient (Pre-Cambrian) rocks; occurrences of the *Glossopteris* plants and of Permo-Carboniferous glacial deposits overlying the older rocks clearly link this shield with the similar areas of peninsular India, Africa, eastern South America and Antarctica—all, according to theories of continental drift once part of the ancient continent Gondwanaland. There are a few areas of later deposition, mostly marginal to the shield; such deposition is Cambrian in the Barkly tableland (northeast), Permian in the northwest desert basin, Mesozoic along the west coast, Tertiary in the Nullarbor plain or Eucla basin at the head of the Great Australian bight. The heart of the continent is occupied by the low much-eroded Macdonnell and Musgrave ranges but in large areas (Gibson, Great Victoria, Great Sandy and Simpson deserts) the solid rocks are hidden by fixed dunes. Very little of this immense area exceeds 2,000 ft. in height.

The eastern margin of the continent is very different: a belt of highlands, curving through about 2,400 mi. from Cape York to South East cape (Tasmania). It seems probable that Australia once extended far to the north and east, so that the true boundary of the Pacific basin is the line New Guinea-Solomons-New Hebrides-New Zealand; in any case much of this area for long ages formed the Tasman geosyncline, the folded, warped and broken sediments of which form the series of ridges and plateaus that make up the Eastern highlands. These are generally around 2,000 ft. high north of 28° S. and 2,000–6,000 ft. in New South Wales and eastern Victoria. It should be noted that the term Great Dividing range is a misnomer; there is no continuous range and the divide itself coincides only here and there with a well-marked ridge. Erosion by short rivers on the rainier eastern flanks and diversion of drainage by basalt flows or by differential earth movements have brought the watershed in many places well to the west of the general line of maximum elevation.

Between the Eastern highlands and the western shield is a broad depression (mostly less than 500 ft.) from the Gulf of Carpentaria to western Victoria; this is floored for the most part by relatively soft rocks (Jurassic-Tertiary) and contains the Great Artesian basin and that of the Murray-Darling, by far the largest river system of the continent. On the southwest this great lowland is flanked by the fault blocks of the Mt. Lofty and Flinders ranges of South Australia.

The landscapes of the continent are thus in general subdued, since the highest point is not much more than 7,000 ft. above sea level; indeed only about 180,000 sq.mi. (about 7% of the area is more than 2,000 ft., a proportion far smaller than that of any other continent. The east coast is dissected by fairly deep valleys forested with eucalypts or occasionally with jungles of Indo-Malayan affinities. At intervals there are small coastal plains or wider valleys, such as those behind Brisbane and Sydney; well watered and moderately fertile, these are among the most prosperous regions of Australia. The highest elevation is close to the Pacific coast with its rain-bearing southeast trade winds and there is little marked elevation in more than three-quarters of the continent. These facts largely account for the aridity that is so marked a feature of Australian geography and is by far the most serious impediment to economic development. West of the Eastern highlands the vegetation of Australia is predominantly drought-resistant—open eucalypt woodland, savanna, *Acacia* (mulga) or eucalypt (mallee) scrub, steppe and desert.

Rivers and Drainage.—A girdle around Australia has normal ("exoreic") drainage to the sea, but even this is broken in three places by riverless areas abutting on the coast. Only in the south-east quadrant—the Murray-Darling basin—has the girdle much depth. Over much of this normal drainage area the rivers flow only in the wet season, or even only once in several years.

Between longitude 120° and 135° E. and latitude 18° and 33° S., there are virtually no rivers. This "areic" area reaches the coast in the desert basin in the northwest and in the Nullarbor plain; while on the South Australia-Victoria border is another small riverless area. This lack of drainage is partly the result of lack of rainfall and partly because of the cover of sand over porous rocks, while the Nullarbor plain is a limestone area riddled with solution channels, such water as there is coming out in springs

along the cliffs on the coast.

The joint Murray-Darling basin covers about 440,000 sq.mi., but of these only about 158,000 sq.mi. are effective catchment; nearly two-thirds of the basin normally supplies no water to the two trunks. The Darling, Australia's longest river (1,702 mi.), has been dry for as long as 18 months; the Murray (1,609 mi.), the only really great river, has dried up on three occasions (1830, 1912, 1922). The Paroo normally fails on the last 30 mi. before it joins the Darling, but in the 1870 floods it was navigated for 180 mi. above the confluence and had spread to a width of 60 mi. On the plains the rivers of this system branch and reunite to an extent only excelled by those of the Channel country. This feature is associated with the very slight gradients, low banks and occasional but very violent flooding.

Though the Murray and the Darling and two or three of their tributaries receive enough rain in the highlands to reach the main stream (with diminished flow downstream), really well-developed perennial streams are restricted to the extreme southwest corner of the continent, the north coasts and the Eastern highlands. There is very little river navigation, except for short coastal reaches in the east and for 50–100 mi. or so on some of the northern streams, where navigation tends to be very hazardous. The development of railways and irrigation killed the once-flourishing traffic on the Murray-Darling.

Of the many inland ("endoreic") drainage basins, that of Lake Eyre is the largest—nearly 500,000 sq.mi. The complex branching or braided patterns of the Murray-Darling are repeated on a grander scale in the Channel country, the Queensland portion of the basin, by the Barcoo river (Cooper creek), the Diamantina, the Mulligan and other "rivers"; some of these simply disappear into Simpson desert, while the Hay has perhaps never flowed during the past century. The main channels, however, have water holes which are generally permanent and may be several miles long; indeed in much of Australia the word river really implies a chain of sausage-shaped pieces of water. The waters of this immense basin, when there are any, converge on Lake Eyre (39 ft. below sea level) or on one of the other remnants (Gregory, Frome, etc.) of a lake that in Pleistocene times covered 40,000 sq.mi. Lake Eyre itself, 90 mi. by 40 mi., is usually a sheet of salt on which a truck can be driven; the "shore" is formed in part by the fossil delta of the Barcoo. In 1950, however, the Barcoo and the Queensland rivers were in high flood and the lake lived up to its name.

The "lakes" dotted about the maps of Western Australia are for the most part mere playas, normally only salt flats. The Eastern highlands and the Murray valley, however, contain many small lakes of various types, posing the most interesting problems of origin. The best known is Lake George, near Canberra, which occupies a tiny interior drainage basin in well-watered country. When full, three or four times in a century, Lake George is 15 mi. long, but it is generally dry land used for pasture.

Artesian Water and Irrigation.—Problems of water supply and conservation are among the major preoccupations of Australians. The aridity of the interior is to some extent mitigated by the presence of a number of artesian basins (fig. 1), including the Great Australian or Artesian basin, which occupies no fewer than 678,000 sq.mi. (including the intake) and is by far the largest artesian area in the world, covering most of the Darling and Lake Eyre catchments and extending north to the Gulf of Carpentaria. The aquifers are mainly Jurassic, capped by impermeable Lower Cretaceous shales and sandstones. The theory that the water is plutonic—originating at great depth—is generally abandoned; the intake is mostly from a narrow but continuous belt on the western flanks of the highlands, from the gulf to Dubbo in New South Wales. Under the artesian pressure some waters rise to the surface in "mound springs," volcanolike hillocks or even small hills, up to 130 ft. high, of calcareous sinter; there is a notable group of these south and east of Lake Eyre.

As the water supply is the rainfall of the intake belt, it is quite possible for exploitation to exceed replenishment, and indeed of 2,000 bores drilled in Queensland in about 60 years, 1,300 had ceased to flow by 1943. There are altogether approximately 7,500 artesian and subartesian bores, down to 7,000 ft. deep, producing more than 300,000,000 gal. per day. Individual bores have yielded 4,000,000–5,000,000 gal. daily. As in other Australian artesian basins (though less so than in most), the water is as a rule too saline for continuous irrigation. It is used here and there for gardens, but is most valuable for watering stock: perhaps 20% of Australia's sheep are wholly or partly dependent on artesian supplies. But, although it is possible that equilibrium may be reached in some areas, the diminution of flow gives rise to some anxiety and more economic utilization is essential. Most of the bore water is lost by seepage or evaporation from tanks or from thousands of miles of open earth channels and it is obvious that the lining of these or, better, their replacement by pipes, would be a long and costly process.

The Murravian basin is on the whole much more saline than the Great Artesian, but the waters of its southern half are extensively used for stock in the Victorian mallee. None of the other basins is exploited on more than a local scale in places for town supplies.

Irrigation in Australia is mainly in the Murray valley: of a total of less than 2,000,000 ac. irrigated, the Murray and its tributaries Murrumbidgee and Goulburn account for 88%. Of the total, nearly two-thirds is used for pastures, lucerne (alfalfa) and fodder for dairy cows and sheep. Most of the remainder is used for cereals, mainly wheat, though practically all Australia's rice is grown by irrigation from the Murrumbidgee. For the rest, vines and citrus fruits are the main items; irrigation began in 1887 in "Sunraysia," the home of the dried fruits industry around Mildura, Victoria, and most of this industry depends on pumping irrigation from the Murray there and in South Australia. The largest works are the Burrinjuck dam on the Murrumbidgee and the Hume on the Murray; the latter impounds 1,250,000 ac.ft., enough to keep the river in flow for two years; Burrinjuck's capacity is half this. The diversion into the Murray basin of water from the Glenelg and the Snowy will add appreciably to irrigation potential.

Possibilities of expansion are hardly spectacular. Apart from its salinity, artesian water is in general uneconomic. Australia's irrigation storage capacity could perhaps be multiplied two and a half times, commanding perhaps 5,000–7,000 sq.mi. But this would still be mainly in the southeast, with a few fair-sized units in Northern Territory and a large number of small ones in Queensland. Such development would, of course, take a very long time and would still affect only a minute fraction of the continent, leaving almost untouched the more arid areas.

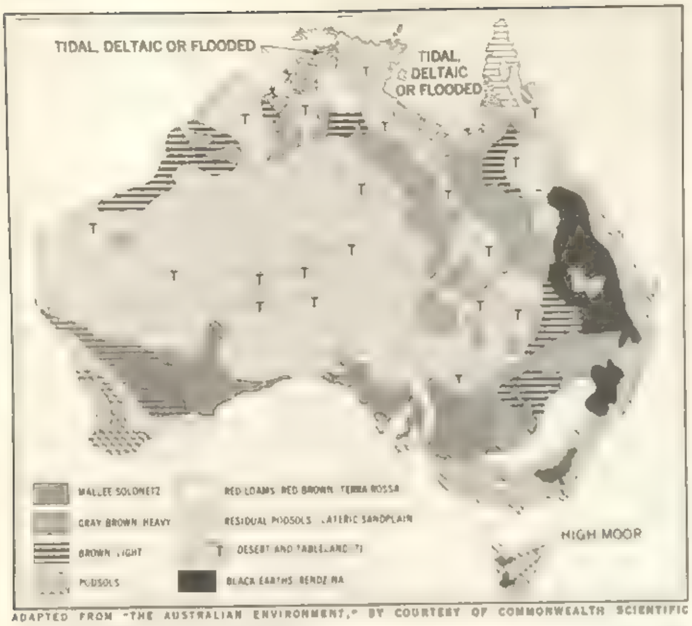
For the rest, the Australian continent, especially in the more or less marginal pastoral areas, is dotted with thousands of small tanks, fed by artesian wells, wind or engine-driven pumps or the local rain. There are also many miles of pipeline from hill reservoirs for domestic or stock supplies. The 350-mi.-long pipe to Kalgoorlie, for example, was largely turned to agricultural or pastoral uses as the gold fields and their demand declined.

D. Soils

The core of Australia—the enormous area bounded by the line of 15-in. rainfall in the north and the 10-in. line in the south —is occupied by desert or semidesert soils: desert loams; sand dunes; gibber plains of wind-faceted pebbles; or bare rock. There is as a rule more vegetation than in the Sahara. In the north there are large areas of skeletal "tableland" soils. The groups so far mentioned account for 56.5% of the total area of Australia and, if used at all, support only a very few cattle or sheep.

Around this arid core are: the semiarid brown, gray and solonized soils; the subhumid red-brown and black earths; and the humid podsolized soils (fig. 2).

In the first group, the heavier gray and brown clays, with discontinuous lime or gypsum horizons, deposited in old alluvial or lacustrine plains, carry steppe or very lightly treed savanna and form as a rule very good grazing lands, as do the lighter brown soils. The mallee soils, associated with the stunted eucalypt



ADAPTED FROM "THE AUSTRALIAN ENVIRONMENT," BY COURTESY OF COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATON

FIG. 2.—MAJOR SOIL GROUPS IN AUSTRALIA

of that name, are highly calcareous and alkaline, generally sandy though with some clays; developed in areas with 17 in. of rain or less, they have been leached by saline waters and in the south have been much affected by wind action, which has produced long east-west sand ridges. The mallee soils have been largely reclaimed for wheat and sheep farming and are better than the much-leached acidic *solonets* soils of Western Australia. In detail, the soil pattern in the largest continuous area of agricultural importance, the Murray basin, is very complex, an important role being played by the "fossil levees" of a prior (Pleistocene) semi-deltaic river system.

The best soils of Australia are the subhumid: black earths, deep alkaline or neutral clays; *rendzinas*, alkaline light clays or loams: these are developed mainly on the downs of Queensland. The red-browns are formed in the 15- to 25-in. rainfall zone, under Mediterranean conditions (dry winter) in the south and monsoon conditions (dry summer) in the north; as a rule, leaching has concentrated soluble salts in an alkaline clay layer, above which is an acid loam; these are particularly valuable wheat lands. Also in this group are scattered red loams on basalt and terra rossa on limestone, the former being among the most fertile soils of the continent.

With more than 20 in. of rain, podsols and podsolized soils tend to be developed; textures (usually rather light) and structures are very variable. In some areas these are associated near the surface with ironstone or ironstone gravel, which are relics of former widespread laterization. The soils of this group usually carry sclerophyll eucalypt forest, breaking down to scrub or heath on the poorer lateritics. The more heavily leached podsols are not very acid but by and large the level of fertility in the whole of this group is low or very low.

There are relatively few areas of very fertile soil in Australia. In the southwest the soils are highly saline and in the southeast overirrigation or poor drainage can result in deleterious saline concentrations in mallee soils and even in the heavier brown and gray soils. Notable advances have been made in the improvement of Australian soils by the addition of trace minerals such as manganese, copper, cobalt, zinc, etc.

Deforestation and overgrazing produced serious soil erosion, by water or wind, particularly on the southern Eastern highlands (gullying), the mallee country (wind erosion under cultivation) and most of the Darling basin and the country north of the south Australian gulfs (wind erosion through overgrazing).

E. CLIMATE

The overwhelming importance of climate in Australian life is reflected in the speech of the people; the ordinary man talks of the amount of rain received during the season in points (a point is 0.01 in.) and knows how far it is above or below normal.

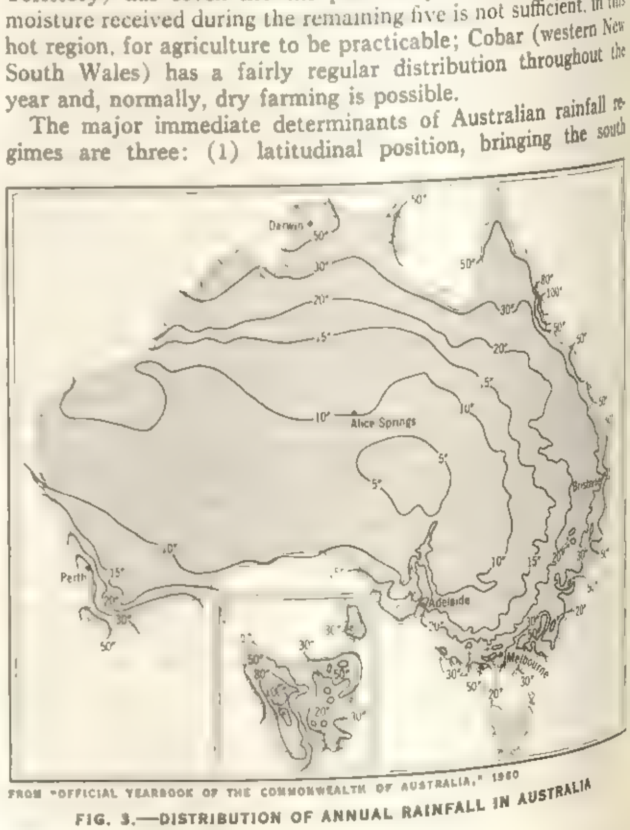
A compact land mass, mainly in trade-wind latitudes, Australia tends to have a continental climate. This tendency is to some extent masked by the fact that the great bulk of the population lives in areas accessible to much maritime influence. Temperature ranges are not indeed great—only in the interior, in a broad belt along the Tropic of Capricorn, are they more than 30° F.; but the seasonal change is enough to produce a monsoonal effect over the northern third of the continent. The northern coasts range from means of 75° F. in July to more than 85° in January, the south from 50°–55° to 65°–75°. The southern part of the Eastern highlands and much of Tasmania fall below 45° F. in July, and the winter there is too cold for continuous plant growth. Snow falls on the highlands as far north as Brisbane, but only very occasionally at altitudes below 2,000 ft.; only above 5,000 ft. or so is it at all common. South of 25° S. frosts may occur from June to August even on the lowlands, and some crop damage may be caused by spring frosts. The southwest and southeast of the mainland may indeed be compared to Mediterranean Europe.

A marked feature of spring and summer in the south is the succession of low-pressure troughs bringing first very hot, dry (often dust-laden) northerlies, called brickfielders, from the interior, followed by the cool and moist southerly winds, called busters, from the sea; the short but intense spells of heat can seriously injure young crops. North of the tropic, practically all the coastlands have at least six months with mean wet-bulb temperatures of more than 70° F., which is high enough to cause discomfort.

Fig. 3 shows how small a proportion of Australia can be called humid; actually only 11% of the area gets more than 40 in. of rain, while two-thirds has less than 20 in. Australia is easily the most arid of the continents.

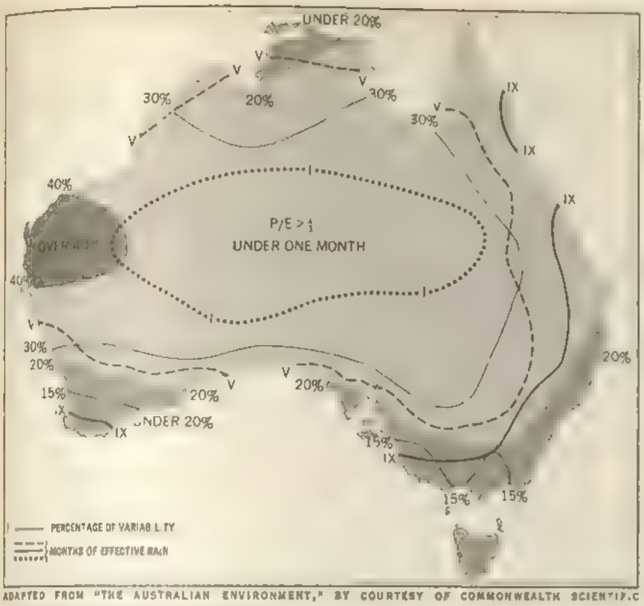
The seasonal distribution of rain, however, is practically as significant as its amount. G. Taylor's comparison of four stations, each with an average of 15 in., brings this out. In Western Australia, Roebourne's average includes yearly totals as low as 0.13 in. and as high as 42 in.; Northam, in the southwest, has most of its rain during the winter months, and this concentration is enough for good wheat farming; Tennant Creek (Northern Territory) has seven months practically without rain, and the moisture received during the remaining five is not sufficient, in this hot region, for agriculture to be practicable; Cobar (western New South Wales) has a fairly regular distribution throughout the year and, normally, dry farming is possible.

The major immediate determinants of Australian rainfall regimes are three: (1) latitudinal position, bringing the south



FROM "OFFICIAL YEARBOOK OF THE COMMONWEALTH OF AUSTRALIA," 1960

FIG. 3.—DISTRIBUTION OF ANNUAL RAINFALL IN AUSTRALIA



ADAPTED FROM "THE AUSTRALIAN ENVIRONMENT," BY COURTESY OF COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

FIG. 4.—VARIABILITY AND EFFECTIVENESS OF RAINFALL IN AUSTRALIA (*see* TEXT)

within the range of temperate westerly cyclones when the main planetary pressure belts swing north in winter; (2) the marked monsoonal effect, with high pressures dominating the north in the dry winter and a summer low pressure bringing rain; (3) the long coast exposed to the southeast trades blowing across open seas and bringing relatively high and regular rain to the Eastern highlands. "The climate [of the western two-thirds] is of the orthodox monsoonal type north from about 20° S. and is orthodox Mediterranean south from about 32° (or farther north near the Indian ocean), the intermediate desert zone lying too far away from the tracks of rain-bearing storms to benefit regularly either in summer or winter." (G. W. Leeper, *The Australian Environment* [1950].) It must be added that the northern coasts, though averaging more than 35 in., are subject to a dry season of up to nine months, which severely limits agricultural possibilities.

The east coast is generally well watered at all seasons. The highest rainfall of Australia, 179 in., is found at Tully (near Cairns), and only the extreme southeast corner, around Cape Howe, gets less than 40 in. Inland conditions are not so favourable: southeast Queensland and northeast New South Wales are reasonably humid for nearly all the year; but even in the wetter eastern half of the Murray basin (at least away from the highlands), though the distribution of rain throughout the year appears fairly regular when averaged, the summer rain is so unreliable as to be in practice ineffective.

Variability is indeed of supreme importance. Except for the winter rain areas of the south, Australia has a variability greater than the mean world variability and for much the greater part of the continent the deviation from the world figure is more than 10%. Fig. 4 shows variability by the mean deviation from the average expressed as a percentage of that average; it should be noted that roughly one year in five will have a rainfall departing from the average by the percentage given in any area *and below that average*. Variability shows a strong tendency to increase with a decrease in the total amount—an inverse correlation; another factor that adds greatly to the precariousness of agriculture in marginal regions.

This discussion may be summed up by considering the effectiveness of rainfall (*see* again fig. 4). Effectiveness for agriculture depends on the relation between the retention of moisture in the soil (P) and the loss by evaporation (E). On open water surfaces evaporation is greater than total rainfall everywhere except in the Eastern highlands; loss from the soil is much less, but this fact alone is clearly significant. Computation of effectiveness is becoming more refined every year, but the formula used on the map, which seems generally adequate for Australian conditions, considers effective rain to be that greater than one-third of evaporation from open water $\left(\frac{P}{E}>\frac{1}{3}\right)$, computed for each month. The five-month line is critical: with less than five months' effective rain, agriculture is practically ruled out except for some quick-growing crops in areas with a high water table (valley bottoms, etc.) in the tropical monsoon region. With more than nine months' rain, intensive dairying and agriculture are possible, except where winter cold or rugged terrain (or both) inhibit them. From all this it will be seen that only the southwest corner and the eastern fringe of Australia are really well favoured agriculturally, with a broader inner belt where conditions are more or less marginal and precarious. (O. H. K. S.)

F. Vegetation

Effects of Rainfall.—The vegetation of Australia is distributed generally according to the same pattern as the annual rainfall. Indeed, it may be said that varying aridity of the environment and moisture conditions of the soil are the dominating factors. Thus the water supply tends to increase from the interior coastward, with the rainfall contours and zones of vegetation roughly parallel to the periphery of the continent.

Only in the southern parts of southwestern Australia, in the Darwin area of the north and down the east coast from Cape York to Brisbane is there a vegetation approaching the tropical forest. In the southwest such forests are dominated by the giant gum trees, many of which attain an average height of more than 200 ft. In the warmer regions of the north, mixed forests with hoop and bunya pines, belonging to the same genus, *Araucaria*, as the monkey puzzle tree of South America, are important constituents. Many broad-leaved trees are also met in the rain forests of the extreme north. In a slightly lower rainfall area forests of *Eucalyptus* are characteristic, occupying a curved belt roughly in the zone where there is about 20 in. of rainfall or even less. As conditions become drier, toward the interior, there are areas where the characteristic vegetation is either the dwarf *Eucalyptus* scrub, known as mallee, or dwarf *Acacia* scrub, known as mulga. As the rainfall diminishes these scrub communities pass into characteristically more sparse desert vegetation. There, as a result of the high evaporation, the soil becomes saline and a saltbush type of vegetation develops in which species of *Atriplex, Kochia* and *Salicornia* are conspicuous features, while where the open community is sandy and less saline, tufted grasses with very sharply pointed leaves are characteristic; of these the most prevalent are species of porcupine grass (*Triodia* species) and cane grass (*Spinifex paradoxus*). The Nullarbor plain, so-called from the

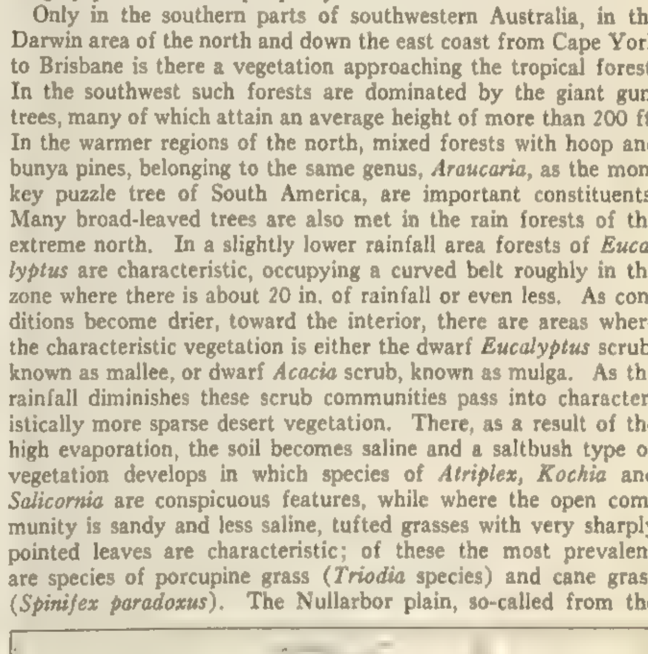


FIG. 5.—GENERAL FEATURES OF THE VEGETATION ZONES IN AUSTRALIA

absence of trees, constitutes the southern part of a stretch of desert that extends from the coast of the bight in the south, practically to the northwest coast near Port Hedland. This plain, in effect, isolates southwestern Australia which is bounded by the open sea toward the west and by the vast expanse of desert on the east. Corresponding with this environmental isolation the vegetation of southwestern Australia is exceedingly rich in endemic species.

Endemics and General Characteristics.—Australia as a whole, however, is characterized by the occurrence of many groups that do not occur elsewhere and by the marked preponderance of certain families and genera. The myrtle family (Myrtaceae) is one such. To this family belongs the genus *Eucalyptus* which is represented in Australia by probably more than 600 species ranging from the stunted mallee types of the arid interior to giant trees such as the so-called mountain ash *Eucalyptus regnans*, which is sometimes more than 300 ft. high. To the same family belong the endemic fringeflowers (*Verticordia*), the Geraldton waxflowers (*Chamaelaucium*), the brilliant bottle brushes (*Callistemon* species), *Melaleuca* and many others. *Eucalyptus* trees are evergreen with foliage that has a polished surface that looks rather dull in the brilliant sunshine of midday but glints in the low-angle sunlight of early morning and evening.

Other characteristic features of the Australian flora are the plants of the genus *Acacia*. Many different kinds are known throughout the continent; they range from bushes, which are thorny and quite small, to large trees. Nearly all the Australian species have leaflike structures that represent flattened leafstalks (phyllodes) and it is usually only in the juvenile foliage of their seedling stages that the pinnate leaflets are developed.

A visitor to Australia would also be struck by the grass trees belonging to the endemic genera *Xanthorrhoea* and *Kingia*; these have stems bearing a large tuft of grasslike leaves and in the former genus dark reed-macelike spikes of flowers. From the base of the old leaves a resin is produced which renders them peculiarly inflammable. There are a number of other characteristic families and genera (*e.g.*, Goodeniaceae, Dilleniaceae, Stylidiaceae and many Rutaceae).

Among the more interesting endemic trees of Australia may be mentioned the parasitic Christmas tree (*Nuytsia*), the bottle tree of Queensland (*Brachychiton rupestris*) and the coniferous *Phyllocladus rhomboidalis*, which forms dense forests in Tasmania and bears deciduous leaflike twigs, the leaves themselves being mere scales.

Most members of the flora are characterized by a thick, relatively impermeable cuticle, which serves as a marked check to loss of water. Although many of the Australian shrubs are thus particularly resistant to drought they are often difficult to cultivate and intolerant of root disturbance.

As a result of the aridity of the climate bush fires are frequent and the seeds of many species are not only fire-resistant but rarely germinate freely except after fire has passed over them; as a consequence, *Acacia* seedlings are often abundant after the first rains following a forest fire.

Regional Vegetation.—The vegetation of the southwest bears a striking resemblance to that of southwest Cape of Good Hope, but the large number of species of heath (*Erica*) that characterize the South African area is replaced in Australia by plants of similar habit belonging to the Epacridaceae. Again, the members of the family Proteaceae, a family that also occurs in Cape of Good Hope, are a striking feature of the southwest Australian flora but the place of the proteas in the South African vegetation is taken by species of *Banksia* and *Dryandra* in the Australian. There is evidence from fossil remains that the Proteaceae in Australia were more widespread in recent geological times than they are today. The members of this group have usually dense inflorescences and crowded small flowers in which the insertion of the four stamens on the tips of the perianth segments is a characteristic feature. Other important Australian genera of this group are *Grevillea* and *Hakea*. It is a family that illustrates to a marked degree the development by vegetation of mechanical resistance to water loss, the anatomical structure of the leaves being of such a character that it is extremely difficult for them to shrink. Indeed, after being exposed all day to the hot Australian sun they look little different from when first gathered. Another group common to Australia and the Cape of Good Hope is the rushlike Restionaceae. The remarkable *Cephalotus follicularis*, which feeds on insects and has pitcherlike leaves, is found in swamps of the southwest. The monotypic lycopod, *Phylloglossum drummondii*, occurs locally in damp sandy areas.

The drier parts of Australia are rich in terrestrial orchids while epiphytic orchids are found in the rain forests of the north and east. Among the terrestrial orchids, two of the most remarkable are subterranean saprophytic species belonging to the monotypic genera *Rhizanthella* and *Cryptanthemis*, both of which possess minute flowers crowded in daisylike heads, borne on a stout underground stem, which emerge at the surface before seed dispersal. In the drier parts, also, switch plants with a restricted leaf surface are common and a particularly striking example is seen in the she-oaks belonging to the genus *Casuarina*. In these the leaves are reduced to mere scales and the green twigs of the tree, which carry on the normal function of leaves, are strongly ribbed with the stomata restricted to and protected in the grooves.

The desert areas after the spring rains are often carpeted with sheets of annuals, especially the small everlastings belonging to the genus *Helipterum*, a particular species being frequently dominant over extensive areas. These and the other desert annuals germinate with remarkable rapidity and may pass through their entire life history within a few weeks. Since the rainfall when it occurs is frequently in the form of a few heavy storms, sometimes more than one season may elapse before conditions are again favourable for germination.

The coastal regions of western and southern Australia are often characterized by marked soil deficiencies, notably zinc, copper, cobalt and sometimes molybdenum. The cobalt is important in the nutrition of the ruminants and the other three trace elements are often the limiting factor in the growth of vegetation. Artificial replacement of these elements and the use of the introduced subterranean clover revolutionized the agriculture of these areas.

Particularly in parts where man has modified the natural vegetation, there is a great prevalence of introduced species, especially those from South Africa and the Mediterranean, some of which have become major pests. At one time the American prickly pear was spreading in Queensland at the rate of 1,000,000 ac. a year, but this was biologically controlled by the moth *Cactoblastis* (*see* NATURALIZATION, PLANT AND ANIMAL). In southern Australia the Mediterranean bugloss *Echium plantagineum* is significantly known as Patterson's curse, the poisonous South African iridaceous *Homeria* rendered many pastures toxic to cattle, while many citrus orchards display a yellow carpet of the South African soursob, *Oxalis pes-caprae*, which was originally introduced to Australia as a garden plant. (E. J. S.)

G. Animal Life

Because Australia is the most isolated of the continents, many forms of life, long since exterminated elsewhere, survive there. Among these are the world's only egg-laying mammals or monotremes (platypus and echidna), whose method of reproduction and whose certain other features directly link them with the reptiles. Australia has air-breathing lungfish (*Neoceratodus*), which are among the only survivors of a group that was widespread and prominent in the Devonian period. There is also an interesting primitive mountain shrimp (*Anaspides*). An example of animals that now have a very patchy distribution, including that in Australia, is the group of fresh-water tortoises known as the Chelidae. All Australian tortoises belong to this group, which occurs elsewhere only in New Guinea and South America, intermediate areas being occupied by other types that may, therefore, have secondarily replaced the chelids in those areas. A further consequence of Australia's isolation is seen in cases where only a single stock within a group has been able to colonize the continent and this stock has radiated out to fill all the available "niches," or ways of life. Apart from the well-known case of the marsupials, which represent an old group, this can be well seen in the snakes. Almost

all Australian snakes belong to the Elapidae, the front-fanged snakes, whereas elsewhere in the world this group takes second place to the fangless or rear-fanged Colubridae. An interesting side light here is that the elapids are believed by herpetologists to be derived from colubrids; if this is so it would mean that, in contrast with the situation in mammals, it was the progenitors of a relatively "advanced" type that was able to colonize Australia and undergo radiation, not the older ancestors themselves.

It is an oversimplification, but nevertheless helpful, to think of the animal life of the Australian continent at three levels: (1) the older forms that have remained relatively unchanged for considerable periods of time or that antedate the Tertiary, which is the period when Australia is believed to have become cut off from the rest of the world (estimated at 50,000,000 years)—the tortoises referred to above and many invertebrates can be placed in this category; (2) those forms of life that largely developed by radiation within the continent during the prolonged period of isolation—most of the marsupials fall into this category; and (3) the more recent arrivals that have colonized the continent by "island hopping" from Asia—rodents and bats are examples of this category.

Early History of the Animal Life.—The early history of plant and animal life on the Australian continent is vague and little known. Extensive invertebrate fossil beds occur extending back to the Cambrian, if not before. Fish faunas from the Silurian, Devonian and thence through to the Triassic occur in various places and have been analyzed. Labyrinthodonts from the Permian and Triassic are known, including a fine 11-ft.-long *Cyclotosaurus*. Ichthyosaur, plesiosaur, turtle and some dinosaur fossils are well developed in the extensive Cretaceous beds that outcrop over much of the interior of Queensland. The fossil reptile faunas of Australia have, however, not been the subject of extensive survey and study as have those of other continents. The oldest known fossil marsupial (*Wynyardia*) is Upper Miocene and both types of monotreme are known from the Pliocene in Australia. The rarity of good Tertiary fossil deposits has meant that little has been learned of the ancestral history and early stages in the radiation of the Australian marsupials.

As elsewhere, giant forms of animal life flourished in Australia during the Pleistocene. These included giant ratites, a varanid lizard that is estimated to have been 16 ft. long, and a series of large marsupials that included *Diprotodon*, a bulky vegetation feeder that resembled a rhinoceros in size, a kangaroo (*Palorchestes*) said to have been 10 ft. high and a marsupial cave "lion" (*Thylacoleo*).

At one time zoogeographers were much impressed by apparent direct relationships between the floras and faunas of Australia and South America (and to a lesser extent Africa), it being postulated that, in former geological times, there must have been a direct contact between these continents by way of Antarctica. The general tendency now, however, is to regard the southern continents as sanctuaries in which animal types that formerly had a world-wide range have been able to persist.

The Living Animals.—The land and fresh-water fauna of Australia today is made up of about 240 mammal species (119 marsupials and 2–3 monotremes, the rest placentals), 520 birds, about 380 reptiles, 112 frogs (but no urodeles), 180 fresh-water fish, 750 mollusks and perhaps 40,000–50,000 insects, as well as a reasonably rich fauna of crustacea, earthworms and other invertebrates. In keeping with Australia's being the smallest continent the gross number of animal species, however, is dwarfed by the larger land masses.

Mammals.—The marsupials, which compose almost half the fauna, are remarkable not only for the degree to which they have radiated in Australia but for the way in which the resultant ecological types have come to mimic, in shape and form, the corresponding but unrelated placental mammals occupying the other continents of the world. Thus there is a marsupial "wolf" (*Thylacinus*), a marsupial "mole" (*Notoryctes*), marsupial "cats" (*Dasyurus*) and a marsupial anteater (*Myrmecobius*). The kangaroolike animals (Macropodidae), which range in size from that of a hare to species in which the male may exceed six feet in height, are the browsing animals of the Australian countryside. The phalangers (Phalangeridae), only slightly less important than the macropodids, are tree dwellers living either on foliage, insects or nectar, or a combination of these. Some species have developed gliding membranes similar to those of the flying squirrels of the northern hemisphere and the "flying lemurs," or colugos, of Asia. There are many species of small marsupials that, superficially, are ratlike and shrewlike. The koala (*Phascolarctos*) is a highly specialized arboreal eucalyptus leaf feeder. The wombats (*Phascolomis*, etc.) are heavy-bodied, terrestrial, burrowing species that feed on grass.

Australia has a land and fresh-water placental mammal fauna that approximates, in number of species, that of the marsupials. All, however, are either bats or rodents, except for one dog. The ancestors of the first two obviously reached Australia by "island hopping," a form of colonization presenting little problem to the volant bats, with the rodents apparently using drifting logs. The dingo was introduced by aboriginal man as a camp dog, about 6,000 to 8,000 years ago.

Birds.—Included here are two large flightless birds (emu and cassowary), the lyrebird (*Menura*), well known for the mimicry, remarkable tail and elaborate dancing displays of the male, and the bowerbirds (Ptilonorhynchidae), most of which build play mounds. The honey eaters (Meliphagidae) have radiated into 67 species, and there are about 50 parrot species, ranging from small nectar feeders to large, heavy-bodied seed-eating and cone-eating cockatoos. There are numerous species of ducks, kingfishers, cuckoos, quail, flycatchers and warblerlike birds.

Reptiles and Amphibia.—Included in the reptile fauna are about 130 snake species, perhaps 240 different lizards, 13 fresh-water tortoises and 2 crocodiles. Though a high proportion of the snakes are venomous only a half-dozen species are dangerous to man.

The Australian frogs include a wide diversity of ecological types. An extreme adaptation to environment is seen in the desert water-holding frog, *Cyclorana platycephalus*. This species, with the drying out of the water holes it frequents, buries beneath the bed to a distance of a foot or more, distends its body with water so that it has a roundness suggestive of a tennis ball and, in a miniature chamber partly sealed by dried mucus, survives until the next rain. Alternatively the tiny black and yellow corroboree frog (*Pseudophryne corroboree*), living for the most part above the 5,000-ft. level, is able to survive beneath the snow for four to five months.

Invertebrates.—Most insect groups exhibit the effects of prolonged geographic isolation. Thus some groups of grasshoppers, leafhoppers, termites, ants and others have undergone a marked radiation in the manner of the marsupials, parrots and elapid snakes. Primitive species appear in many groups; *e.g.*, the termite *Mastotermes*, extinct elsewhere, survives in northern Australia as the world's most primitive termite. Likewise the rare ant *Nothomyrmecia* of the southwest of the continent is possibly the world's most primitive ant. In contrast with these cases, of course, the greater part of the insect fauna generally approximates that found elsewhere in the world. Among the invertebrates there is also the giant earthworm of Gippsland, Victoria, which at fullest extent measures ten feet or more.

Summary.—The mammalian fauna has suffered greatly from European settlement. The clearing of the forest and the hunting have had a direct effect. There has also been a general, and inadequately documented, indirect effect due to the ravages of the introduced rabbit and fox, and the widespread development of the pastoral industry. Over wide areas the rabbit and sheep have removed the ground cover so necessary to some of the smaller marsupials. The effect of this has been shown by a survey of the marsupials of New South Wales by B. Marlow in which it was disclosed that approximately 40% of the species has not been recorded since 1910. Some of these, of course, have never been common and others still occur farther afield. The survey has, however, indicated the perilous state of a sizable segment of the marsupial fauna. Fortunately, other animal groups are not so vulnerable. Probably not more than three bird species have become extinct since settlement.

Australia has become conscious of the need for national parks

during the 20th century, though the areas set aside for conservation vary greatly from state to state. The koala has been nurtured in special reserves and is building up in numbers in the wild in various parts of the range. The two unique egg-laying mammals, the platypus and echidna, are quite common. (A. K.)

II. THE PEOPLE

Until 1788 Australia was inhabited only by aborigines (*see* AUSTRALIAN ABORIGINES), numbering then about 350,000, though some estimates have put the figure as low as 150,000. Contact with white settlers resulted in their constant decrease until fewer than 40,000 full bloods remained by 1930. They are now increasing. There are also more than 39,000 aborigines of mixed blood (including those assimilated in the general community) and more than 5,000 Torres strait islanders. Apart from a very few mixed bloods, no Tasmanian aborigines remain. European settlement, begun in Jan. 1788 with just over 1,000 persons, reached 405,000 in 1850, 3,765,000 in 1900 and almost 7,000,000 in 1939.

According to the census of 1961, 10,418,761 were of European stock, 9,535,665 being British; 91.5% of the latter were Australian by birth. There were 9,984,709 persons of British nationality (allegiance). The non-British Europeans included roughly 454,000 of southern and central European birth and 347,000 from northern Europe. Persons of non-European stock, excluding aborigines and Torres strait islanders, numbered 36,608; *i.e.*,.35% of the total population (10,508,186). These included 20,382 Chinese; 4,195 from India, Pakistan and Ceylon; and 1,063 Malays. These figures reflect a large number of Asian students.

A vigorous immigration policy has been implemented since World War II. Persons arriving between Oct. 1945 and March 1964 and residing in Australia either permanently or for a long term numbered 2,090,175, including 280,930 refugees and 1,039,216 assisted immigrants. Of the total, 1,056,832 were British and 503,000 southern and central European (383,000 being Italians and Greeks). Of northern, non-British Europeans, the Dutch (134,555) were the most numerous. Births to immigrants (1945–64) were estimated at 3,740,760. Nearly half of the 933,343 non-British immigrants have been naturalized. Newspapers and journals in about a dozen languages are produced by and for the non-British immigrant groups. Some of these have formed their own separate clubs. There are also international clubs and good-neighbour councils that encourage assimilation. The language newspapers and "national" clubs do the same, as well as minister to the nostalgia that immigrants must feel in the transition period of settling in large numbers in a new country. The children, however, attend the general schools and become part of, and are accepted into, the Australian community. The newcomers, especially the cultured refugees of the periods before and after World War II, brought a quickened interest in the arts and new ideas about food; but it is doubtful whether they noticeably influenced Australian culture and life.

Just under 60% of Australians are concentrated in the heavily industrialized mainland state capitals and in the important industrial regions of Newcastle and Wollongong. The existence of vast semiarid and arid regions inland, and of the difficult, tropical and often rugged northern regions, retards intensive development of the continent, apart from a 200-mi. (320-km.)-wide strip on the east and southeast and on the southwest. Progress there depends on more scientific research. In the meantime, sparse, pastoral occupation of half the inland area is reasonably effective.

In addition to the European, aboriginal and very small Asian racial stocks in Australia, the populations of the territory of Papua and the trust territory of New Guinea (including the northern end of the Melanesian islands) must be considered. They are administered together. The population figures for these territories (1961) were 1,947,031 indigenous, 19,962 European and the rest, 5,368, Chinese, mixed-blood and others. The Chinese are mostly in the trust territory, where they have lived since before World War I.

The indigenous racial constitution is complex. A reasonable view is that Australoids occupied parts of the main island in their general movement south. Later came Papuasians, descended from the same main stock but with a fuzzy hair mutation. They mixed in some regions with the Australoids and also became differentiated into subgroups through the isolating nature of the environment and normal genetic processes; *e.g.*, the pygmy groups in the island are Papuan dwarfs. Finally, some Melanesians entered from the east.

Intensive research in physical anthropology has shown that the problem is even more complicated. It suggests that an early population occupied the coastal regions, north and south, but moved up to the highlands because of better conditions. They were especially marked by possessing the S gene in high frequency, but little or no M. A later immigrant wave, possessing little or no S but a moderate frequency of M, imposed itself on these, pushing them back and mixing with those who did not go. Later other people intruded sporadically, especially at the eastern end, causing different blood pictures. As a result of mixing and of normal variations over a long period, the highland peoples are now of a uniformly shorter stature than the coastal peoples and also have a greater frequency of light-coloured skins (near white) and different physical appearance. Further, there are distinct enclaves of peoples in some rugged regions who have not mixed to any appreciable extent with either the highland or coastal inhabitants. The Kukukuku are an example. Finally, by 1960 no light had been shed either on the problem of enclaves or on the racial relationships of New Guinea peoples to any peoples of Asia and Oceania so far studied. (*See* AUSTRALIAN LANGUAGES.)

III. HISTORY

Early Beliefs.—The long delay in the discovery and settlement of Australia was caused by many factors—vastness of the Pacific ocean, ideas from antiquity of the impassability of the torrid zone, fears of being cast against the east or west coasts of Terra Australis by prevailing winds and lack of any sign that the land possessed anything worth having.

In the 13th century Marco Polo referred to a well-governed kingdom in the south which grew spices and drugs. This was taken to mean a land much south of the equator, but it seems that Marco Polo meant nothing farther south than Sumatra. The mistaken interpretation, however, influenced European geographers; they continued to refer to a southern continent, and monarchs and navigators continued to be interested in its discovery. There were Portuguese, Spanish and French voyages into the Pacific and Indian oceans and the waters around Indonesia in the 16th century. Some discoveries were made, but it seems that none of the very early voyagers into these regions actually saw Australia.

It was not until 1577 that the first expedition primarily designed to search for lands in the vicinity of Australia actually took place. The main interest was still in trade but there was also hope of obtaining gold and silver. This had arisen from claims made by the 1567 expedition of Alvaro de Mendaña de Neyra from Peru in respect to the discovery of the Solomons. Soon there were signs of activity in England. A group of men in Devon described a beautiful Terra Australis with civilized natives with whom favourable relations could be easily established and from whom large quantities of gold and silver could be obtained. Following upon this attractive and mostly imaginary picture, instructions were drafted in 1577 for Capt. Francis Drake to pass through the Strait of Magellan and to sail west to latitude 30°. He was expected to find new lands, establish headquarters for the sale of English cloth, and to obtain gold, silver, spices, drugs and other commodities. It seemed reasonable to assume that territory like that of the East Indies, containing many of the same products, would extend to the south and east. However, once he had entered the Pacific, Drake turned north to Peru instead of sailing west. His realism is believed to have led him to where he knew gold and silver was to be had for the taking, rather than to explore an unknown ocean in search of gains conjured up in fertile imaginations. Although Drake did not search for Terra Australis as instructed, the event shows a practical English interest in discovery in the Pacific and the reasons for it.

Discovery.—Spanish and Dutch voyages into the Pacific from the east continued. In 1605–06 Willem Jansz sailed close to the northern coast of Queensland but did not actually pass through the strait between it and New Guinea. He was probably the first European actually to reach the coast of Australia. Five months later Luis de Torres, in the one vessel left of an expedition sent by Philip III of Spain, sailed through Torres strait from the east and probably sighted the northern point of what is now Cape York. The impressions gained in these expeditions were of a desolate coast, inhabited by "wild, cruel, black savages" and promising no commercial advantage whatever.

Then began Dutch voyages from the west, but none of the navigators seemed willing to go far enough to reach the Australian coasts. From about 1610, several Dutch captains serving the East India company came into contact with the coast of west Australia on their voyages to the East Indies around the Cape of Good Hope. These contacts led the company to become interested in the lands to the south. In 1623 vessels from Amboina visited the coasts of the Gulf of Carpentaria but no reports likely to encourage further attention were made. In 1642 a Dutch expedition planned by Anton van Diemen, governor general of the East Indies, set out to investigate to the west and south of Australia.

This was the first expedition of Abel Janszoon Tasman, who was given instructions to seek a southern route along the westerly wind belt to Spanish South America. He left Batavia and sailed in the direction of Mauritius, then swept south and east with the westerly winds and eventually reached the western shore of Tasmania, naming it Van Diemen's Land. Tasman sailed on to the south of Tasmania but could give no indication of the extent or nature of land to the north. Continuing his eastward voyage he reached New Zealand in Dec. 1642. Passing to the north of the north island he came into the ocean swell from the east and was satisfied to conclude that there would be an uninterrupted ocean passage to South America. Tasman believed that New Zealand was a projecting part of Terra Australis, now believed to extend to the south of it. He then proceeded north, and finally west, to pass on the north side of New Guinea and return to Batavia. Tasman had completely circumnavigated Australia, as though this had been his intention, and had not actually proved a passage to South America. However, his general interpretation was correct.

In 1644 he set out again to try to sail south of New Guinea into the Pacific, and to discover if there was a sea passage between the land around the Gulf of Carpentaria and that known to be farther west. Tasman's report was that there was no Torres strait (the voyage of Torres was unknown to the Dutch), but he was correct in that his voyage westward revealed no sea passage south of New Guinea. Tasman's work brought to an end the phase of exploration associated with the Dutch East India company.

In 1688 William Dampier, one of a crew of pirating adventurers searching for plunder in the East Indies, visited west Australia "to see what the country could afford," but found it most unsuitable for his purposes. However, Dampier published an account of his visit which proved sufficient for the authorities in England to give him command of H.M.S. "Roebuck" to continue exploration of northern Australia. His voyage extended knowledge of New Guinea and New Britain, but did little for lands farther to the south except maintain interest.

There was little of importance in the 60 years that followed Dampier's visit, but the beginning of the second half of the 18th century showed both Britain and France to be interested in further developments. In addition to commercial motives, reasons connected with naval power, scientific discovery and missionary work produced this interest.

In 1768 James Cook was given instructions similar to those given to Drake in 1577. The admiralty was mainly responsible but the Royal society wanted to have astronomical observations made from Tahiti of the transit of Venus. Cook sailed around Cape Horn and reached Tahiti without encountering any land mass, then continued to New Zealand and so removed any doubt about the existence of a clear route from South America. Cook, who

ADAPTED FROM GRIFFITH TAYLOR'S "AUSTRALIA" (METHUEN & CO. LTD.)

FIG. 6.—THE ROUTES OF CHIEF EXPLORERS AND EARLY NAVIGATORS OF AUSTRALIA

was a man of tenacity, skill and balance, went on although his contact with New Zealand probably satisfied his orders, and on April 20, 1770, became the first European to reach the east coast of Australia. Passing northward along the coast, Cook's voyage revealed country that Joseph Banks, the English explorer-naturalist, was able to report upon favourably for use and settlement. For the first time European navigators had seen that part of Australia that did appear suitable for settlement. Reaching the northern point of Queensland, after a hazardous journey, Cook took formal possession of eastern Australia on Aug. 23, 1770. Cook's second voyage in 1772 and his third in 1776 added a great deal to European knowledge of the Pacific and showed that successful voyages could be made from Europe.

Settlement.—In the later stages the main work of discovery of Australia had been done by Englishmen who took possession of it on behalf of the English crown. Settlement of Australia ensured that almost the only influences determining its character were British.

There has been some difference of opinion about the causes of the foundation of a settlement in Australia (*see* E. O'Brien, *The Foundation of Australia* [1936]). Opinion was divided as to whether the settlement was established "deliberately in order to relieve the overcrowding of the gaols," or whether the British government was founding not "a mere gaol but an industrial colony." Few people ever held the latter view without serious qualification.

The first suggestion for the establishment of a British colony in Australia was made before a committee of the house of commons in 1779 by Joseph Banks, who with Cook had seen Australia for himself. Transportation overseas of persons convicted of offenses against the law in England had been practised during the 17th and 18th centuries, but the Revolutionary War then being fought in the American colonies prevented further transportation there of convicted persons. The eventual victory of the American colonies, the continued practice of judges of sentencing convicted persons to transportation and the marked increase in offenses caused by the social upheavals of enclosure of land, obsolescence in several lines of manufacture and trade, and the sudden growth of towns in England made it certain that a new outlet for offenders had to be found. Banks believed that Australia was ideally suited for this purpose. It was so distant from any other civilized place that escape would be difficult; there was little chance of opposition from the natives; the climate was mild; the soil was capable of sustaining a large number of people; there were no beasts of prey; and there was an abundance of timber and fuel.

In addition to wanting a place to which convicts could be sent, the government thought it would have to provide a home for

American loyalists in difficulties resulting from their enemy's victory. But when the Pitt government came to office (1784) it was concerned only with the practical problem of getting rid of convicts. To solve the problem an order in council dated Dec. 6, 1786, appointed "the eastern coast of New South Wales or some of the islands adjacent" as the place to which offenders might be transported. Capt. Arthur Phillip of the Royal Navy was commissioned as the first governor. At this date Great Britain, under the belief that New South Wales might be separated from what the Dutch called New Holland, did not lay claim to all Australia, but just the eastern coast and all islands adjacent in the Pacific. The governor was to take the usual oaths of office; he was given power to pardon and reprieve offenders, to levy forces for the defense of the colony, to withstand pirates and rebels, enforce discipline, make land grants and to exercise general jurisdiction. The powers and duties of the governor made it clear that the British government intended the colony to be controlled as a jail and meant the governor, through his staff and "police," to employ directly most of the convicts and to keep their produce as a government stock. The possibilities of private land ownership and employment of convicts and others were always visible but it was clear that the British government considered that for many years the government in the colony would perform most of the administrative and directive work. It was clear also that the British government intended to devote the very minimum in money and materials to the settlement. Between his appointment and the departure of the first fleet for Botany bay nine months later on May 13, 1787, Phillip had persisted in efforts to obtain more stores and equipment for his expedition, so much so that it has been concluded that by the time it sailed the idea of founding a commercial settlement was very definitely afoot. It was, however, never much more than "in the air." The first fleet was very poorly equipped and the convicts and their guards arrived with very little with which to contend with the forests of New South Wales. Whatever had been the intention of the government in 1787, the outbreak of war with France in 1793 made it certain that little time and money would be devoted to a convict settlement on the other side of the world.

The Early Years.—Soon after arrival Phillip decided that Botany bay was unsuitable and moved his 11 vessels to Port Jackson. This harbour, which he described as the "finest in the world," became the scene of his settlement and of Australia's greatest city. There reached Sydney 736 convicts, of whom 188 were women. Guarded by 191 marines, under 19 officers, they reached a country accurately described as "forest-clad, unkempt, uncanny and unknown," and one on which Phillip reported: "No country offers less assistance to first settlers." Hardly had the fleet arrived when the marine guards, claiming that their duties did not extend beyond the voyage out, refused to act any longer. A special unit, the New South Wales corps, was enlisted in England to act as guards, or a police force, in the colony.

In the meantime Phillip had to do the best he could but found his community of convicts were as well behaved as most of the towns in England from which they had come. Expecting supplies and assistance, he was soon dismayed to see the second fleet—three ships—loaded not with provisions but with more convicts. It left England with 1,017 aboard; 267 died on the voyage and 486 of those who did arrive were sick. Of these, 50 died in the first month, and those "not classed as sick were hardly able to attend themselves." It was described as a "ghastly company of sick and dying. . . . Great numbers were slung over the ships side in the same manner as they would sling a cask." However, Phillip showed an energetic devotion to the growth of the settlement, which was in part shared by many of these poor, cruelly treated people, and he felt very soon able to report a belief that "This country will prove the most valuable acquisition Great Britain ever made." But other officers of the colony were of a different opinion, seeing at first no future in the colony for themselves and then no future in it for anyone but themselves. Some obstructed the governor in his work, as well as encouraging the British government to do nothing to change a policy of neglect.

During Phillip's time there was therefore revealed a political separation of interests—on the one side capable, energetic free men with privilege and money anxious to obtain control of convict labour on slave conditions and of all commercial activities; and on the other a government with a considerable measure of responsibility to see to the employment and rehabilitation of the convicts.

Houses and public buildings were erected of timber and, when bricklayers were discovered among the convicts, of bricks. Phillip led exploration of the colony, and settlements were established at Parramatta, on the Hawkesbury river and at Norfolk Island. Almost immediately grants of land were made to men who had arrived free, and convict labour was provided for its working. By 1791 more land was in use under government direction than private, but by that year 150 persons were in possession of farms. Cultivation had been attempted on all farms, but crops were poor, for hardly any rain fell in the year before Phillip's departure from the colony. By the middle of 1790 only 38 convicts had been assigned to private employment and care was being taken to see they were properly employed and treated. By 1792 the settlement was producing its requirements in several types of manufactured goods.

Failing health compelled Phillip to relinquish his command, but by his departure in 1792 the settlement had progressed sufficiently far to allow it to be said that by that date the foundation of Australia had been achieved. Phillip was able to report: "The colony is approaching to that State in which I have so long and anxiously wished to see it." Further, he felt confident that "Time will remove all difficulties." While the achievement had been remarkable, there were great difficulties ahead, but never was there any doubt of importance that the settlement would survive.

Exploration, 1796–1845.—Australia was explored both by land and sea. George Bass and Matthew Flinders in 1796 explored much of the coasts of New South Wales in small whaleboats, and in 1798 Bass made a long and successful voyage in his small whaleboat around the east and south coasts of the colony proving the existence of a strait between the mainland and Tasmania (*see* fig. 6).

Until 1813 nothing was known of New South Wales beyond a coastal strip about 150 mi. long and no more than 50 mi. wide. The colony was shut in much more by the Blue mountains on the west than by the sea on the east. In 1813 Gregory Blaxland, William Lawson and W. C. Wentworth penetrated through this canyoned plateau, almost as deep as it is high, on a journey that marked the beginning of the occupation of the interior, as well as the beginning of the problems of its more extensive exploration. Soon it would be no longer any easier to confine the graziers to the boundaries of settlement than "to confine the Arabs of the desert within a circle drawn on the sands." From the bases established beyond the mountains a few small expeditions went farther and discovered rivers flowing west and southwest. The nature of the country farther to the west was not, however, to be revealed for a good many years.

In the meantime land to the north and the south of the main centre of settlement was explored. John Oxley, G. V. Evans and Allan Cunningham went north, and Hamilton Hume and William Hovell and Thomas Mitchell went south. The northern explorers discovered great tracts of land suitable for settlement, and in 1823 Oxley traveled nearly 700 mi. N. of Sydney, discovering on the journey the Brisbane river which was to become the site of the capital of the northern state of Australia. In 1824 Hume and Hovell began what was to prove the most important journey since the Blue mountains were first crossed. They traveled southwest to reach first the Murrumbidgee river, then Australia's greatest river—the Murray, as it was later named—and then to cross the full width of what was to become the state of Victoria. This expedition revealed not only great possibilities for the extension of settlement in New South Wales but even greater possibilities farther to the south. At about the same time, Cunningham carried out more exploration in the southern part of Queensland.

Concerned with the problem of the large rivers flowing west Gov. Sir Ralph Darling sent out Charles Sturt in 1828 to try to discover their course and destination. Sturt traveled more than

300 mi. to the west to reach a large river which he called the Darling. The problem still remained unsolved. In 1831 Sturt traveled down the Murrumbidgee river and into the Murray. This journey of nearly 2,000 mi. proved the Murray to be the centre of a northern network of rivers, but still there were rivers farther to the north that flowed out to the west; perhaps they flowed toward some inland sea, perhaps they came to an end in dry, shingly beds. In 1836 Thomas Mitchell traced the Darling river southward to the Murray, and then continued south across the western end of Victoria to reach the coast at Portland, where he discovered a settlement already established. The Hentys, who were there, had traveled by sea from Tasmania. Mitchell continued from Portland diagonally across Victoria on his return to Sydney. The expedition demonstrated not only the extent of land available for settlement but also its fertility and accessibility. However, in 1840–41 the great efforts of Edward John Eyre in exploring land to the north and west of Adelaide were unrewarded by such discoveries. His journey toward the centre of Australia revealed dry salt pans instead of an inland sea, and that along the coast of the Great Australian bight again revealed land totally unsuited for use of any description. In 1845 Charles Sturt added greatly to the knowledge of the area toward the centre but he found nothing to justify any optimism about it. Later journeys toward the centre did witness the rare sight of Lake Eyre full of water.

Later Exploration.—Exploration of northern Queensland continued about the same time. In 1844 Ludwig Leichhardt traveled through the swamps, forests and grassy plains extending around the Gulf of Carpentaria in an expedition of 19 months' duration. This journey caught the imagination of the colonists and produced great enthusiasm for the extension of settlement. In 1848 Leichhardt attempted the hazardous crossing of the continent from east to west but he was never heard of again.

Ten years later the main interest concentrated upon crossing the continent from south to north. In 1860 John McDouall Stuart set out in an attempt to win £10,000 offered by the government of South Australia to the man who first made this journey. Stuart successfully reached the centre of Australia, but soon afterward had to abandon his journey. The following year he again failed at much the same latitude.

About the same time the Victorian government and public provided funds for a similar expedition to travel from Melbourne to the Gulf of Carpentaria. Equipped at a cost of £12,000 this expedition set out in 1860. It had been planned to establish bases, and those sections that were able to move more rapidly were to go on ahead and prepare for those bringing the more bulky supplies. Having reached the Barcoo, Robert O'Hara Burke, the headstrong leader, impatient of the arrival of others of his party, decided to make the rest of the journey to the gulf with only three companions, William John Wills, John King and George Grey. These four men actually succeeded in reaching the sound of the sea, but were unable to penetrate the swamps and jungle scrub. On the way back, Grey died of exhaustion. When the others returned to the base at the Barcoo the camp was deserted. The rest of the party, instructed to remain three months, waited just over four, but had left the very morning of the day Burke, Wills and King staggered in. They were able to find food, deposited in a marked spot, which would have been sufficient to get them to the nearest town, but Burke decided to make for Adelaide. After traveling many miles Wills was left with a supply of food and water, while the other two, better able to travel, went in search of a native camp. Two days later Burke died of sheer exhaustion. King returned to the place where Wills had been left and found him dead. He struggled on until he found a native camp and remained three months with the natives, until eventually he was found by a search party. This ill-fated expedition of Burke and Wills demonstrates just how tremendous a task the exploration, let alone settlement and development, of Australia was.

In 1862 Stuart further extended knowledge of the territory north of Adelaide by traveling well beyond the most northerly point he had reached the year before. He continued through Arnhem Land, along a river he believed to be the Adelaide but later claimed to be the Mary (a large river farther to the east), and to the shores of the Indian ocean. In 1874 explorations based at Perth in west Australia began: John Forrest traveled north and then made a wide sweep toward the centre of Australia. In the same year Ernest Giles traveled from Adelaide to Perth across the northern part of the Nullarbor plain and then, leaving Perth, turned north for 600 mi., finally crossing the central Australian desert in an easterly direction. The expeditions from Adelaide and Perth during the 15 years before 1875 proved a large part of Australia to be unsuitable for settlement.

By 1875 all the main geographical features of Australia were known. However, a good deal of exploration of Western Australia, Queensland and the Northern Territory was carried out after 1875—indeed there was still room for a good deal more in the second half of the 20th century. These later explorations were usually searches for minerals or for greater knowledge of the aboriginal natives. While it is true that very little of Australia remained unexplored at mid-20th century there was still a great deal of Australia about which very little was known. The demand for uranium, for example, gave new interest and value to parts of Australia previously regarded as useless.

The New South Wales Corps.—When Governor Phillip departed in 1792, the senior officers of the New South Wales corps took over control. Probably no less than 16,000 ac. of land were granted between Phillip's departure and the arrival of Gov. John Hunter in 1795. The small group of corps officers and their friends possessed a great advantage in trade—few others received income in currency that was acceptable by those who shipped goods to the colony. What is more they possessed powers to apply the law or not to apply it, even if not the actual power to say what the law was. Acquisition of land, of advantages in trade and of favour at the hands of "the law" ensured that they would become a wealthy and powerful group.

Hunter's main problems continued to be those of making the colony survive—the employment of convicts and emancipists (convicts who had served out their sentences) and the production of food and other necessities; but it was soon apparent that the activities of the New South Wales corps, particularly the officers, represented a serious difficulty. The governor endeavoured to apply the policy laid down by the British government, with the aid of men whose interests were that it should not prevail. The substance of this political conflict was economic interest. The officers and their associates desired to have convicts assigned to them for employment at their own terms and to dispose of their products at the best prices obtainable. They desired to buy, or otherwise acquire, goods at prices most favourable to themselves and enter directly into the disposal of them. They desired nothing less than a monopoly of the import trade, particularly that in rum. The early governors, on the other hand, proceeded to employ many convicts on government land, to take their produce into government stores and to dispose of it at prices determined by considerations other than making the most profit. Goods were also imported by the government and sold from its own stores. This practice had arisen because at first there had been no other way and then because of the existence of men able to exercise monopoly powers.

The acquisition and disposal of rum, in particular, became a problem. It became the customary currency, the normal means of paying wages, and its possession depended either upon having silver and gold money which shippers would accept or upon distilling it unlawfully. This "exchange economy based on tyranny and rum," which on balance was most harmful to the small community and its future, produced also the kind of initiative and ambition that gave Australia, in its very early years, the sheep industry upon which all its future prosperity was to depend. John Macarthur, the pioneer of the wool industry, was not only the personification of all that had produced so much evil and so much good but he was the man whose egotism and drive was directly responsible for so much of it.

While the colony in its first decade was growing in population (only a trickle of it was free), in land under cultivation, in output and range of goods, in the number of buildings erected and the

extension of settlement, difficulties with the group led by the corps officers grew also. Hunter returned to England in 1800 exhausted by his labours. Uprisings by Irish and other convicts early in the 19th century were perhaps more dramatic but far less significant than the acquisition of power by the corps. P. G. King, Hunter's successor as governor, a man of strong character and fiery temperament, believed he could do better. However, despite his orders and his indignation, the balance of political, social and economic power continued to move in the direction of the corps officers. Conditions of life and employment of convicts and emancipists—well over 90% of the community—did not improve during King's term of office, but the colony made progress. The conflict of governor and corps officers came to a head in King's time with a duel between Macarthur and his own senior officer, William Paterson, who was carrying out the governor's orders. The opposition led by Macarthur was not completely successful and Macarthur himself was sent to England to face court-martial. King, however, was left in a weakened position and was soon recalled. Macarthur, in England, took the opportunity to resign from the corps and to develop his plans for land and sheep farming in Australia.

Sharpening of the Conflict.—The appointment in 1805 of William Bligh (famous for the "Bounty" mutiny) as governor of the colony made a sharpening of the conflict inevitable. Bligh knew what his instructions meant and he determined to carry them out. The general lines of British government policy remained the same throughout the years 1788–1821, and Bligh proceeded to give effect to it. His defeat at the hands of the New South Wales corps merely meant that the British government realized that its governors could not work without power independent of the dominant colonial pressure group; and, under Macquarie, the policy the corps sought to defeat triumphed. Issues that led to an insurrection by the New South Wales corps centred in matters of trade, particularly illicit dealings in rum, and in the acquisition of land rather than in anything relating to wool growing or the affairs of the pastoralists. Bligh's policy was recognized by the "little men" to be in their interests, but the power of the corps officers in effecting Macarthur's aims was too great.

Following Bligh's arrest in Government house and his detention, the main activity of the military government was that of granting land, strengthening its own position and clipping the wings of its competitors. The employment of convicts became little better than slavery and the retention of a society permanently divided into free and unfree seemed certain.

Macquarie.—The success of the New South Wales corps and Macarthur was their undoing. Orders were given for the corps's removal to England and Macarthur, too, left the scene of his conquests for some time. Lachlan Macquarie was appointed governor with the power to bring his own regiment to the colony. With this power to enforce his own decisions, Macquarie arrived to find the select group, "pure merinos" as they were later to be called, in a dominant economic and social position. Macquarie has often been described as a despot, and no doubt a despot he was to those people who desired to see a colony of great inequality between free and unfree, rich and poor. His policy increased the prospects of emancipation for convicts and their chances of gaining status and of becoming small farmers in their own right. He caused public buildings and roads to be constructed, established a bank, encouraged exploration and the pastoral industry and introduced currency to take the place of rum. He redressed the balance of social and economic power over a period of ten years and, as during these years it became certain that no section of the community would ever succeed in completely dominating all others, production and settlement increased and extended. No doubt there would have been more economic progress in certain fields if sectional initiative, if not ruthlessness, had been given its head, and by 1817 there was room for a change in policy in certain directions. Complaints uttered about Macquarie's administration led to the appointment in that year of Commissioner J. T. Bigge to investigate. The British objected strongly to the amount of Macquarie's public works expenditure, and some influential persons in England and Australia desired the emancipists to be given less and the big landowners more scope. This conjunction of interests resulted in the termination of Macquarie's period of office in 1821.

It could now be truly said that Australia was established on a firm economic foundation and in a manner that would not allow any great disparities to develop between groups of its people. Both Macarthur and Macquarie deserve credit for this situation, the first for vigour and personal ambition and an interest that served the colony well, and the second for holding a proper balance within the colony itself and for determining to give it the public facilities essential if it was to function.

Growth of Self-Government.—Sir Thomas Brisbane, who succeeded Macquarie for four years, permitted the colony to put forth its economic, social and political strength. It was not until near the end of Brisbane's term of office that new lines of policy were applied. In the early 1820s there were demands for a more liberal form of government and for more power to be centred in New South Wales rather than in the British government and exercised by governors. The other aims of the time were for more land to be secured in large lots and for more labour to be available at lower wages. In 1823 an act, based on Bigge's report, established a small council of persons to be appointed in New South Wales to advise the governor on the passage of laws and imposition of taxes for local purposes. It also provided a jury of military officers.

Sir Ralph Darling succeeded Brisbane in 1825 and he immediately strengthened the hand of the large landowners and those who desired to limit the powers of government. He reported in 1830 of the "humiliating condition of my few radical opponents who are in fact driven from society." This was not the case, but during Darling's term of office land grants took place on a colossal scale. In 1828 alone 91 new grants were made, totaling about 150,000 ac.; 30 were of 2,560 ac. each. At the same time it was decided that no grant of less than 320 ac. was to be made and a grant of land to a Sydney bootmaker was refused because it was "not the policy of the government to make grants to tradesmen or those without capital." Capital was required for speedy development and it was believed that this policy would encourage people with capital to come from England to the colony. It had some measure of success and the foundations were laid for a marked development of the pastoral industry in the 1830s.

Darling was followed by Sir Richard Bourke, a man of more liberal mind and more generosity to tradesmen and those without capital. However, by 1835 those who were politically of significance did not differ much in what they wanted. Not only was expansion taking place but the population was increasing as a result of the schemes of assisted migration that had been adopted. The emancipist leaders and many of the native-born had become rich, the emancipists had been able to break down many of the social barriers and many within these groups began to approximate to the "exclusives" in their aims. Bourke reported at the end of his term that ". . . there would soon be an irresistible demand for a Representative assembly unless some sensible concessions were made." Not only was a more representative government wanted but a more responsible one was wanted also. In the latter part of the 1830s there was a strong demand for a transfer of power from the British government to the colony, but there was no strong demand for anything like a fully representative government. Those with influence wanted a restricted property franchise but no power given to the government to upset the social pattern. Legislation passed in England in 1842 answered these requirements. The new council was to consist of 36 members, 12 to be appointed by the queen and 24 to be elected on a property franchise. The council acquired control of all revenue other than that required for the governor's household, but the control of land sales and the revenue therefrom remained in England.

The end of the 1830s, a decade of expansion and prosperity, saw a severe depression. Free and assisted immigration had been a disappointment; although land had been made available, labour was scarcer and dearer than employers desired. The first serious financial crisis that came in 1841 depressed activity for two years and

although there was a slight improvement after that, the whole of the 1840s was a period of very slow growth.

Land Policy and Transportation.—Upon his arrival in 1838 the governor, George Gipps, soon became aware of his most serious problem—on the one hand to do justice to those who had obtained use of large areas of land under licence for grazing their sheep, and on the other "to hold land as a trustee for the population of the future." The first six years of the 1840s were full of the events of economic depression and the conflict of Governor Gipps and the "squatters" (sheep owners). Sheep were boiled down for tallow because wool and meat would not sell. Unemployment was widespread and there was a great deal of discontent in the towns. Gipps endeavoured to balance his obligations but he, too, was denounced as a despot.

Wage earners, small farmers and shopkeepers all supported Benjamin Boyd, W. C. Wentworth and the Macarthurs in their demands, first, for colonial control of land policy, and second, for the grant of a title or security to the squatters. Many people in this alignment against the governor had nothing to gain and much to lose from the success of these aims. Squatters and large landowners did gain much, but much was held for posterity and there was no change at this point in the control of land policy.

The year 1847 brought evidence that economic conditions had changed for the better, and brought too a new issue in colonial politics. Transportation of criminals from England to New South Wales had come to an end in 1840. In 1846 the colonial secretary, W. E. Gladstone, pointed out that the reintroduction of transportation was a matter for the colony alone, but her majesty's government "were disposed to doubt whether the absolute exclusion of transported convicts from New South Wales should continue." Henry Parkes believed that in 1847 the reintroduction of "the transportation of British convicts to the colony was assuming irresistible importance." Decisions in the legislative council were sometimes against, sometimes for it, and in all this it became evident that wage earners, shopkeepers and town dwellers were opposed to transportation while the squatters or graziers favoured it. On the strength of a council decision in favour, the British government sent out a ship full of convicts. The "Hashemy" arrived in Melbourne in 1849 and public protests against the landing of the passengers caused the authorities to move the ship on to Sydney. There the public protest was even greater and the "Hashemy" moved on to Brisbane where the convicts were landed. Antitransportation leagues were formed and great public agitation led to a slight change in the composition of the legislative council. In Aug. 1849 a resolution was passed "that no more convicts ought under any circumstances be sent to any part of the colony."

Political Development.—These contests over land policy and transportation were of great importance in the political development of the colony. They had a great deal more influence on the growth of democracy there than the people who regard the effects of gold discoveries as of primary importance in this respect have been disposed to represent. New South Wales proceeded a long way toward democratic or representative government, if not responsible government, in the 1840s. However, both representation and responsibility had to await the discovery of gold for fuller realization. Gold in 1851 changed a pattern of trade and rural depression and slow desultory growth in population into one of fantastic expansion. But by 1850 New South Wales and the Port Phillip district were politically if not economically ripe for such events. Responsible government particularly was seen to depend upon the colony's producing a sufficient level of wealth to allow its costs to be met within the colony. Gold allowed certainty to take the place of doubt in respect to this. But it was clear even before 1850 that the British government considered that how far the colony's government should be representative or democratic was a matter mainly for the people who lived there.

In 1850 the Australian Colonies Government act was passed in England. It separated Victoria from New South Wales and the franchise for the colonial parliaments was made a little more representative, but the government in England was not willing to transfer control of land policy and revenue from land sales to the colonies. But in 1852 the British government pointed out that the discovery of gold had "thus advanced the people in wealth and prosperity" and it was decided that complete control of land could be transferred to the colonies after certain constitutional changes had been effected. The government in England was eager to see a bicameral legislature, but otherwise was less concerned with the franchise than with the way in which the costs of colonial government would be met. Now that the colonial parliaments had power to make their own constitutions they turned at once to the job. However, within Australia almost all the influences that were at work in hammering out the first one were found in New South Wales. Wentworth led the group that tried to establish a hereditary upper house, but opposition was too great and its supporters had to be satisfied with a house nominated by the governor on the advice of the assembly, which itself was elected on a fairly wide male franchise. The constitution in Victoria followed closely on the lines of what had been done in New South Wales, but Victoria, following advice from England, established a council elected on a property franchise.

From 1823 Van Diemen's Land (renamed Tasmania in 1853) had an appointed council to advise the governor in the same way as New South Wales and this act applied until 1850. South Australia acquired the broadened council provided in the act of 1842. These colonies also acquired new constitutions in the years after 1853. In all the colonies adult males elected the assemblies, but the upper houses, the councils, remained appointive as in New South Wales, or elected on a restricted property franchise. An adequate understanding of Australian constitutional developments requires reference to the development of the whole British colonial empire toward self-government (*see* COMMONWEALTH OF NATIONS).

Discovery of Gold.—While these political changes were going on, Australia was in the midst of the economic upheaval of the gold discoveries. Gold had been discovered in Australia before and there is no doubt that it had been kept quiet for fear of the disturbances that would follow. Continued depression in Australia and loss of population to California after discoveries of gold there changed the situation. In 1851 E. H. Hargraves, who had been in California, returned to New South Wales and found gold in payable quantities near Bathurst. Soon after, a committee in Victoria was offering rewards for the discovery of gold in that state. They had not long to wait. Discoveries began near Clunes, at Anderson's Creek, near Buninyong and in amazing richness at Ballaarat and Bendigo, and in 1851 gold worth more than £1,000,000 was obtained. At first the prices of all goods and of land rose to fantastic heights; wages too became spectacular. There was a movement of labour from all occupations into the search for gold. Production fell off and, with money demand so great, prices and wages continued to rise. These events received dramatic publicity all over the world and stories of senseless extravagance were legion. Before many months had passed Port Phillip bay was full of ships that had brought people from all over the world as well as goods of all sorts for sale. In 1850 the population of New South Wales and Victoria together had been 265,503 but by 1860 it had become 886,393, and 537,847 of them were in Victoria.

A licence was required for lawful gold prospecting. For those who were successful the cost of the licence was no burden, but for the many unsuccessful diggers it was often more than they could afford. They all objected to the manner in which the law was applied and the possession of licences enforced. Early in 1853 there had been a threat of armed resistance at the Turon in New South Wales, but it was at Ballaarat, the most law-abiding of all the camps, that discontent became a rebellion.

Toward the end of 1854 the Ballaarat Reform league was formed. Its demands included abolition of licences, political reform including four of the six Chartist points and the release of four diggers who had been imprisoned for burning a hotel, the licensee of which had been acquitted of the killing of one of their comrades. Mining licences were burned at a mass meeting on Nov. 29 and on Dec. 2 diggers, after a skirmish with soldiers, assembled in a rough stockade on the Eureka and raised a blue flag bearing the Southern Cross. On the morning of Dec. 3 the stock-

ade was attacked and 30 diggers and 4 soldiers were killed in the fighting. There has always been some difference of opinion about the exact number killed. Martial law was established and changes were made, particularly in the personnel of the police, with the result that many of the grievances were removed.

It was not long before alluvial discoveries began to fall off and deep shafts had to be driven down and mining carried on with the aid of a considerable amount of machinery. Nearly £17,000,000 of gold was obtained in 1852 in Victoria, £12,000,000 in 1853, £8,600,000 in 1854, rising again to £13,000,000 by 1856, then falling continuously until it reached £7,800,000 in 1861. After 1857 opportunities for miners to make a living on the gold fields began to decline seriously. Other occupations soon became oversupplied with labour and attention was turned to the land. Many of the diggers had been farm labourers and they wanted to become farmers. But much of the land that was suitable had been purchased by graziers or was held under licence by squatters. In these circumstances the universal demand became one of "unlocking the lands." Political organizations grew up in Victoria and New South Wales to secure this objective.

Land Reform.—In Victoria about 31,000,000 ac. were held under licence by squatters. In New South Wales the position was that almost all land that could be used for agriculture was already owned or held under licence for grazing. The former diggers had little money, for gold discoveries had not amounted to much for most of them, and for many who had made money the chances of buying land were hardly better, for their money had gone easily. What is more, graziers did not want to sell land but to secure a better title for themselves. In the New South Wales assembly in 1855, Henry Parkes moved that a committee be appointed to inquire into agriculture. Resolutions of this kind were defeated, with reducing majority, until in 1858 John Robertson, a great advocate of change, became secretary for land and works. In 1859 the assembly passed a bill allowing selection of land to be made before survey. This would have allowed farmers to select land from squatters' runs; but the opposition in the council, where the squatters were in the majority, was too great and the bill was defeated. In one form or another conflicts between the assemblies and the councils took place in all the colonies during the next 30 years on issues in which sectional interests were as clear-cut as this one. In 1861 a compromise measure was passed in New South Wales which allowed selections of land to be made, but squatters were able to retain a pre-emptive right to $\frac{1}{25}$ of the run, with an option or prelease over three times the amount they purchased. During the next five years more than 17,000 families settled on the land and some measure of success could be claimed for the legislation. However, the squatters continued to do more than hold their own by methods of "peacocking" (picking out the best parts of the runs, water holes, creeks, etc., so that others could not make use of the rest) and "dummying" (buying land on behalf and in the name of all members of the family and even friends and imaginary persons). In Victoria public agitation was probably more extensive than in New South Wales. A land convention or "peoples' parliament" met near Parliament house in Melbourne. Following upon the introduction of the adult male franchise for the assembly in 1857 great preparations for the following election began. It was a victory for the land reformers. Soon after, a bill was passed in the assembly to allow land to be obtained but it was quickly defeated in the council. Another election soon followed and there was a bigger majority for land reform. Again law was proposed but this time a compromise was reached. This law, called the Gavan Duffy act, met with little success, but in 1865 the first Grant act was passed and in 1869 a second one. Under the first act (from 1864 to 1869), cultivated land rose by 200,000 ac., while under the second (from 1869 to 1878) it rose by 1,102,205 ac.

Economic Difficulties.—During most of these years the Victorian parliament saw great stresses in its battles over protective tariffs. The assembly and the council were again divided—the assembly being mainly elected by those who wanted to set up workshops and factories and by those who wanted to work in them, while the council was mainly elected by those who wanted to buy imported goods as cheaply as possible and export freely. In 1866 the assembly and the tariff supporters won, and Victoria gained its protective tariff. New South Wales continued to remain free-trade. The decade and a half following the exhaustion of alluvial gold was a period of depression. Despite the great flow of gold from the ports, there was a surplus of labour and a shortage of money to employ it. Queensland had been separated from New South Wales in 1859 and for some years economic conditions were difficult there. Throughout the period there had been persistent demands for public works to relieve unemployment. From about 1873 there was a more influential demand, led perhaps by Sir Hercules Robinson, governor of New South Wales, for public works as a fundamental prerequisite for colonial development.

Between 1871 and 1892 at least £220,000,000 was borrowed overseas by New South Wales and Victoria and a good deal of this money was spent on public works—at least £64,000,000 was spent alone on railways in these two colonies. Despite the existence of the great depression in England and no great demand for Australian wool (prices fell throughout most of these years although there was a marked increase in the volume of exports) employment and business began to improve after 1873. Improvement gradually changed into a boom and from 1883 the boom got out of hand into a speculative and unhealthy price inflation.

Further loans were refused in England, at first temporarily. Then a brief lease of life was followed by a complete termination. Building societies, land companies and other purely speculative institutions became bankrupt and the banks began to crash one after another. Strict economy prevailed for several years. It was perhaps necessary to eliminate the large unhealthy section of the economy, but it nevertheless delayed development and recovery.

The Labour Movement.—During the years of the expansion the Australian labour movement began to develop into a new phase. As early as 1824 coopers in Sydney had been committed for trial for "combination." In 1831 there was a Boat Builders Benefit society in Sydney and during the next decade several other trades became similarly organized. In the 1840s trade union or friendly society activities declined but more attention was paid to the organization of political groups. During the 1850s shortage of labour again encouraged the development of trade unions which were successful in obtaining an eight-hour day as well as many advances in wages. However, the gain in organizational and ideological strength had not been great. During the 1860s labour surplus and unemployment compelled the unions to become totally defensive and none was able to hold all its gains. Some unions went out of existence. There was no noticeable increase in their strength until the end of the 1870s. Unions then increased in number and membership. Many of their aims were taken from "New Unionism" in England, from the Socialist league and the Social Democratic federation, branches of which were established in Australia. As the land boom came to an end, employers were no longer willing to grant wage increases as they had done and strikes began to increase. The great strikes of 1888–95 resulted in the total defeat of the trade unions. Unemployment, and the powers of the government that were used against the unions, faced them with defeat or revolution for which they were neither qualified nor very anxious. Their defeat convinced them that they must set up permanent organizations for the exclusive purpose of achieving political power; *i.e.*, of getting their members elected to parliament. They had always been interested in political action but in ways spasmodic and not well-organized. Labour electoral leagues were set up and finally the Australian Labor party came into existence.

Federation.—The financial crisis, while it strengthened the desire for a national structure and government, with a view to greater self-sufficiency and less competition between borrowers on overseas money markets and more financial co-ordination at home, delayed it on balance. Recognition of the need for some over-all co-ordinating machinery had come with the separation of New South Wales and Victoria in the first place. At first the sugges-

tion came from England and led to the appointment in 1851 of the governor of New South Wales as the governor general of Australia. Then advocacy for an Australian nation and government began in New South Wales and Victoria. The first colonial conference met in Melbourne in 1863 and similar conferences continued to meet for a number of years. The object was to reach agreement about matters on which the several state parliaments should legislate uniformly. The adoption by Victoria of a protective tariff in 1866, and its increase in later years, raised a difficulty in the path of federation. In 1880, at a colonial conference, Sir Henry Parkes suggested the formation of a federal council and in 1884 an imperial act created one. It was to exercise certain defined powers but it amounted to nothing in practice, for New South Wales refused to join in. Parkes complained that "this rickety body" would delay making a federation into a real government, but New South Wales had stronger reasons for holding back. The necessary economic conditions for a federation had been created by 1890, but for a time federation had to take a back seat to all the problems that arose from the great strikes, the financial crisis and the bank failures. The main obstructions, however, were the tariff issue separating Victoria and New South Wales and the desire of conservative interests to retain powers for the state government in view of their own strength in the legislative councils. Labour also did not completely favour federation. Some said it was another name for government by the financial interests, particularly those abroad, though it is difficult to see their reasons for these beliefs.

It is difficult to accept the more or less traditional view that the people rose and swept aside these sectional interests and demanded federation. Only 30% of the qualified electors voted for it in the 1898 referendum, and 43% in 1899. Federation came to Australia in 1900 mainly as a result of a cautious compromise of the interested parties, pushed to some extent by organizations seeking nationhood; many of the people opposed it and most of them were far from enthusiastic about it. It meant, however, that an important stage in the development of Australia had been formally registered. It was a development destined to have a great influence upon the future.

An imperial act dated July 9, 1900, federated the colonies into the commonwealth of Australia. The act was later passed in all the parliaments of the colonies. A proclamation was issued in September of the same year, setting out that on Jan. 1, 1901, the people of New South Wales, Victoria, South Australia, Queensland, Western Australia and Tasmania should be united in a federal commonwealth of Australia. The central government obtained certain limited defined powers and the states were left with the residual powers. The commonwealth parliament first met in Melbourne. In Oct. 1908 it was decided to establish a federal capital at Canberra and the first parliament met there in May 1927.

Social Legislation.—These first years of the commonwealth were part of the period of social and economic reconstruction following upon the crisis of 1888–95. They were also years in which new social and political forces produced for the first time a national alignment and policy. The formation of the commonwealth was a historically logical development of the events of the last three decades of the 19th century, but inherent in these events was the determination of labour, through the trade unions and its new political party, to share the control of industry (or the distribution of national income) as well as the control of parliament. The lines of national policy—deliberate action to secure a distribution of national income according to "fair and reasonable" standards—soon became apparent.

The first commonwealth parliament was an assembly of political leaders many of whom had been prominent in state politics and much of whose work was done. Party alignments were difficult to find but no less so than any signs of policy. Most of the members seemed to stand for either protection or free trade. This parliament had to create the machinery for federal administration and had time for little else. The second election in 1903 seemed at first to make little change, but the second prime minister, Alfred Deakin, showing a primary attachment for protective tariffs but also a personal philosophy favourable to social legislation, began soon to skilfully barter arbitration, conciliation and the promise of pensions legislation against Labor party support for tariffs.

In 1904 Australia was not a country in which there was a great deal of social legislation. Education had been in the hands of the churches and private individuals until 1848. In that year a state system began in New South Wales. It was not until about 1880 that education had become mainly secular and paid for by the state, but in 1904 it was not completely costless in the primary stages, and beyond that costs were sufficient to place it beyond the reach of many people. The first Friendly Society acts to regulate the affairs of private organizations had been passed in the 1850s. In 1862 the first Coal Mines Regulation act was passed in New South Wales, and in 1873 the first Australian Factories act was passed in Victoria. It was not until 1885 that an act of much effect in the regulation of factories came into existence. Health acts were passed in most of the colonies between 1870 and 1890. In South Australia the first serious move to provide law for the setting up of courts of conciliation and arbitration came up in 1890 but it was unsuccessful. In New South Wales in 1892 such an act was passed but in practice it had little effect. In 1895, as part of its factory laws, Victoria adopted the system of wages boards, which became of quite wide significance in factory employment. It cannot be said that social legislation in Australia at the turn of the 20th century touched more than a little the lives of many people, nor that it changed appreciably their living conditions.

"New Protection."—Developments during the first decade of the 20th century in the commonwealth and state parliaments consisted of some extension of social legislation and the application of a system of protective tariffs to the commonwealth. In 1904 the commonwealth parliament passed legislation to set up a court of conciliation and arbitration and in 1906 two pieces of tariff legislation became law—the Customs Tariff (Agricultural Machinery) act and the Excise Tariff (Agricultural Machinery) act. The first of these imposed a substantial duty on agricultural machinery imported to Australia, and the second one allowed a rebate of excise duty on such machinery manufactured in Australia, provided that it was the product of labour paid "fair and reasonable" wages. This was known as the "new protection," and it served to tie together the interests of employers and workers in securing a tariff system.

In 1907 the new commonwealth court of conciliation and arbitration was asked to say if the employees of Australia's largest agricultural machinery manufacturer were employed under "fair and reasonable" conditions. The decision was that they were not and that the manufacturer was obliged to pay the excise duty. In expounding this judgment, Justice H. B. Higgins defined the Australian basic wage. While this decision was the subject of appeal before the commonwealth high court, parliament went on with its plans to extend tariff protection to a much wider range of manufactured goods, which the Labor party was induced to support because it believed that new protection or a "fair and reasonable wage" in all such protected industries could be enforced and because the government undertook in return to extend the age and invalid pensions, which had existed in Victoria and New South Wales since 1901, to the commonwealth. This alignment of parties resulted in the passage of the Pensions act on June 4, 1908 (although pensions were not paid until 1910), and the general Customs Tariff act on June 5 of the same year.

But on June 8 the high court held that the principle of new protection was invalid. This meant that there was now little common ground between Labor and the Deakin ministry, and the removal of Labor support brought Deakin together with the free-trade conservatives or, as he put it, with "the whole of my opponents since Federation." The Deakin-Cook administration managed to hold out until the election in 1910, but the Labor party was then returned with a large majority in both houses of the commonwealth parliament. Australia was now definitely a country with a substantial and general tariff, but nothing of substance had yet been gained by Labor as a result of legislation.

The parliaments of the states had been busy during these years

with matters of detail rather than of general policy. Slowly Labor strength increased in several of them and in 1910 the Labor party was in office in New South Wales with a large majority. In the other states the Labor party had been able to exercise the role of a balance of power party and in several of them the structure of social legislation increased as a result. The years 1910 to 1913 were years of general prosperity and the first commonwealth Labor government with a majority, led by Andrew Fisher, was able to round off and extend the social legislation of its predecessors. This was possible also in Queensland, New South Wales, Victoria and South Australia under somewhat different circumstances. In the 1910 session of the commonwealth parliament 40 acts became law. Attempts to secure new protection by constitutional amendment were made but they failed. The Australian Notes act, which confined the issue of notes solely to the government, became law in 1910, and 1911 saw the setting up of the Commonwealth bank. Although a good deal of the program of the Labor parties had become law by 1913 there were signs by that date of a good deal of dissatisfaction with parliamentary action as a means of reform. It was felt that Labor had been outmaneuvered; that they had given their support for tariffs without securing that wages should be kept at such a level that workers would get their share of the gains of the protected industries. However, the commonwealth court of conciliation and arbitration had begun its long job of making decisions about wages and working conditions which, on the whole, up to 1913, had been favourable to the workers. The Fisher government also provided legislation for the establishment of an Australian navy.

The Constitution.—Little happened in the years 1900–14 to the commonwealth constitution. On the whole the high court, the final arbiter of the meaning of the document and of the extent of government powers, adopted a general principle of interpretation that was definitely restrictive of the commonwealth. The principle was that the commonwealth should not be permitted to enter, by way of one of its powers, upon fields that were left under other powers to the states. Soon after World War I, however, there were signs that the high court was to turn for a time to an interpretation more consistent with the growth of a more distinctly national government. However, before this, other changes were to take place and the commonwealth was to become involved by almost universal consent in World War I.

Defense.—Australia's awareness of the problem of defense and its interest in external affairs began almost as soon as the first settlement. In these early days there was some concern at the possibility of French competition for Australian territory. Nothing came of it; indeed there was almost certainly nothing whatever in it. Later, in the 1840s and 1850s, concern with the chance of Russian invasion led to the building of fortified points in Sydney and Melbourne. There was certainly no more in this fear than in the fear of the French. In the 1870s Australia, or sections of it, looked apprehensively at foreign activities in places like New Guinea, and in this mood it sent representatives to the royal commission on the defense of the empire in London in 1880–82. Successive offers of military assistance had been made by Australia to Great Britain in the later 1870s and in 1881 South Australians volunteered for service in South Africa. The first contingent of artillery and infantry ever to leave Australia served in the Sudan in 1885. In 1883 the government of Queensland, impatient with British action, annexed New Guinea in an effort to combat German influence there. In 1889 Maj. Gen. Bevan Edwards visited Australia from England and made a report recommending that the forces of the colonies be placed on a uniform basis under one authority. Soon after this, interest and concern with defense and war seems to have declined in Australia, although the accepted need for a national defense structure did encourage federation.

World War I: Economic Effects.—At the outbreak of World War I in 1914 Australia was in the midst of a commonwealth general election. There was immediate general agreement among all parties that Australia would, and should, give all possible assistance to the prosecution of the war. Andrew Fisher as prime minister, elected as leader of the Labor party with a very substantial majority, pledged Australia in 1914 "to the last man, and the last shilling."

World War I in Australia was not a "total war." Despite a marked increase in manufacturing in the decade before 1914, Australia was predominantly a producer of primary goods. Manufacturing output then accounted for only 27% of total production. Australia was not thought to be in a strong financial position, despite the few years of prosperity, at the outbreak of war. State and commonwealth debts had greatly increased in the years before the war and the orthodox method of acquiring funds for war from loans at home and abroad was adopted. Increases in the note issue and expansion in bank credit followed the increase in expenditure resulting from the disposal of loan funds. A pronounced rise in prices was associated with this, but on the whole the economy was left to accommodate war expenditure within a normal peacetime structure, the government relying upon loans to finance the war. Taxation, of course, increased and the Commonwealth bank and other banks expanded credit. But the war was paid for in Australia very largely by a transfer of income payable later from the community to lenders overseas and at home. The government did enter directly and indirectly into the running of the economy more than ever before, but the Australian economy during World War I remained essentially a market one. There was a decline in productivity and effective wages fell from 975 in 1913 to 865 in 1915, with a recovery before the end of the war to about 950.

Considerable impetus was given to the development of manufacturing. The number of factories increased, there was a widening of the range of products and Australia acquired an iron and steel industry for the first time. The value of manufacturing production, at constant prices, rose by 32%. Agricultural production rose also by 28% but pastoral production fell by more than 21%. The relative rate of industrialization in Australia during World War I can easily be overstated, but it is true that the war shifted the balance sufficiently far to give secondary industry (employers and employees combined) overwhelming political power. Associated with the growth in manufacturing was a growth in the number of trade unions and in their membership. Soon after the war the formal links that had existed between the engineers and woodworkers in Australia and in England were severed because of law and practice widely different in the two countries. Another reason was that the Australian unions had developed a national structure and were of more substantial proportions than before the war. The Tudor tariff of 1921, Australia's most protective up to that time, was an outcome of the increase in industrial bargaining power. The formation of the Australian Country party just after the war was another. From that time the political leaders of Australian farmers were out to secure, by political means, special advantages for farmers of the same economic nature as tariffs and legal minimum wages.

World War I: Military Contribution.—During World War I Australia enlisted 416,809 volunteers, of whom 329,883 served overseas. As the result of war service 59,342 were killed. Australia's first contribution to the war was to hand over to the British government unconditionally the ships and men of the Australian navy and to provide an expeditionary force of 20,000 men for service overseas. The speed at which volunteers offered enabled the size of the Australian imperial force to be rapidly increased. It was at first intended that the Australian troops should go to the main centre of war in Europe, but because training resources in England were overtaxed by British and Canadian troops the Australians were landed in Egypt. After they had helped to repel the Turkish attack on the Suez canal, it was decided that the Australians should take part with the British 29th division and the New Zealand troops in an attempt to force the Dardanelles. On April 25, 1915, the landing at Gallipoli was made. Persistent and heroic fighting continued almost to the end of 1915, when it was finally realized that the geography of the region was such that the limited size of the forces available made final success unattainable and the evacuation was ordered. It was achieved without a single casualty. Soon after

the Australian troops were again encamped in Egypt and it was decided to take all the infantry to France and to keep the light horse brigades, the flying corps and the imperial camel corps in the middle east. These troops remained to play a distinguished part in that theatre of war.

The Australian infantry first entered the western front near Armentières, but by July 1916 the two Australian divisions, now joined by a third, were on the Somme. When they were withdrawn in September they had lost approximately 21,000 men during nine weeks of desperate fighting. The Anzac 1st corps was then moved to the Ypres salient for a short "quiet" period and afterward, reinforced by the 5th Australian division, returned to the Somme. The winter stalemate which followed meant that the troops had to endure all the wretchedness of flood, mud, snow and frost until Feb. 1917, when renewed Allied pressure was rewarded by the German withdrawal to the Hindenburg line.

The Australian troops were engaged in desperate fighting at Arras and Bullecourt, and then the 3rd Australian division, under Maj. Gen. Sir John Monash, took part in the highly successful battle of Messines ridge, north of the Lys river. Then followed the titanic struggle east of Ypres. Australian troops had great success from time to time, finally ending the salient near Polygon wood by a great advance in Oct. 1917. Winter saw the Australian troops in action near Passchendaele, finally to be relieved from complete exhaustion after losing 30,000 men in three weeks' fighting. Soon after this the Australian and New Zealand troops were separated, and the name Anzac was officially dropped.

March 1918 brought the great German offensive and the Australian divisions were hurried back into the fighting. April, June and July found them at Villers-Bretonneux and in Aug. 1918 the Australian and Canadian corps, with British tanks and artillery, took part in the great advance beyond Le Hamel described by Gen. Erich Ludendorff as "the turning point of the war." Finally, Australian troops played a significant part in clearing the way for the assault on the Hindenburg line, which was won on Sept. 29, 1918. Before this, however, several Australian brigades played a vital role in carrying the advance for more than two months; during this period they suffered 21,000 casualties, but took more than 29,000 prisoners as well as capturing 338 guns and a vast amount of other material. The pinnacle of Australian achievement during World War I was the point of the last withdrawal from Montbrehain just a few days before the Armistice.

Postwar Prosperity, 1920–30.—Australia entered the 1920s with a political situation very different from that which preceded the war. The wartime prime minister, W. M. Hughes, had returned to Australia in 1916, convinced that the voluntary system of enlistment for the armed forces should be replaced by conscription. This matter was put to the vote on two occasions in a national referendum and was defeated. But many Labor party leaders including Hughes, W. A. Holman, W. G. Spence and several others—in fact, most of those who had led the party since its organized entry into state and commonwealth politics in the 1890s—supported conscription and were finally expelled from the party. Some of these men joined the opposing parties, Hughes to emerge as leader and to continue as prime minister.

During the three years immediately after the war a new party —the Australian Country party—was formed to capture the vote of country people. Previously many country votes had gone to Labor, and some of the leading figures in the Labor party were returned for country electorates. The rise of the Country party and the severe losses to Labor resulting from the difficulties and defections over conscription meant a marked postwar shift in political power, and Australia was to be governed in the 1920s with very little influence from the labour movement.

The symbol of the new situation was the coming to office of the Bruce ministry in 1923. This was a combination of the Nationalist and Country parties and the slogan "men, money and markets" was soon to set the tone of all that was done. The aims were development of manufacturing and rural industry, immigration and provision of capital from overseas. For the first time since the 1880s the Australian economy became dependent upon money borrowed overseas—this kind of debt rose from £A443,000,000 to £A980,000,000 in the period. Export prices were favourable for most of the time and significant economic development did take place. In 1926 the Patterson butter scheme showed the way farmers wanted to go now that they had obtained new direct political power. It provided for a voluntary levy on all butter sold in Australia (which meant a price higher than it otherwise would have been); out of the proceeds of the levy, farmers who produced the butter were paid a subsidy on that portion of total production that was exported. Simply, this meant a transfer of income within Australia from butter consumers to butter producers, so that Australian butter could be sold at a more competitive price overseas.

Empire development had been emphasized during this decade. But immigration to Australia was a disappointment. Only in one year did immigration exceed half that of 1913 and although much money was borrowed, British investment in Australia could not have increased by more than £A10,000,000 a year. Emphasis upon "men, money and markets" did not mean that much that was "artificial" had not entered into the scheme of things. But much of that which was artificial was noted for its lack of motive force. In economic conditions which on the surface seemed good there was much unrest and uncertainty. Strikes among seamen occurred in 1925 and among timber workers in 1929. Many people felt that protective tariffs had become much too high and an inquiry took place in 1927. The result was a not unreasonable conclusion that tariffs had been beneficial in that the existing (1927) population could not have been supported at the existing standard of living without them, but that tariffs were imposing excessive costs upon certain sectors of the economy. The Bruce-Page ministry went to the people in 1929 on a proposal for the abolition of arbitration in all but the maritime industries. It was overwhelmingly defeated and the prime minister, S. M. Bruce, defeated in his own seat, retired from Australian politics. James Scullin, the leader of the Labor party, became prime minister in an attempt to govern without effective power, for the senate was firmly in the hands of the opposition. In these circumstances the 1930 fall in export prices to an average of about half that of 1928, with the sudden and definite termination of all overseas loans, left Australia in a completely undermined economic situation.

The decade saw interesting developments in the Australian constitution. Barriers that had arisen against commonwealth powers and technical and financial limits upon the states operated to bring the commonwealth and state governments together. Concern with this problem gave rise in 1921 to suggestions for a constitutional convention, but they came to nothing. A royal commission on the constitution, in 1929, produced a report of some practical importance, but the real achievements were in the field of combined commonwealth-state action. In 1928 the Financial agreement resulted in the commonwealth's taking over all state government debts, and the Loan council was set up to control all future borrowings. The Murray River agreement between the commonwealth and the three states—Victoria, New South Wales and South Australia—introduced a plan for water conservation and for irrigation projects to be carried out by the three states. The Main Roads agreement introduced the method whereby the commonwealth provided money so that the state governments could carry out work on main roads. These agreements established the principle that was certain to determine a good deal of the development within the Australian constitution. It meant a central source of finance and a decentralization of the work performed.

Australia ended the decade conscious of its complete dependence on external factors and its inadequacy by internal management to keep up its national income. In traditional manner attention was directed to the distribution of this income.

Depression of the 1930s.—In Aug. 1929 wool prices fell heavily and in the same month London financial houses refused any further long-term loans. The Scullin Labor government came into office in October. They met the situation by orders "mobilizing" Australian gold, and in December large shipments of gold were made to London in an effort to meet current demands

on Australia for payments. The exchange rate of the Australian pound began to depreciate rapidly and seriously. All this was insufficient to stem demands on Australia for payment. In April 1930 there was a heavy increase in a wide range of import duties and in many items direct prohibition of import except on license was imposed. During July and August Sir Otto Niemeyer, representing the Bank of England, visited Australia and presented a statement to the premiers' conference. It proposed the maintenance of parity with sterling and the gold standard (although sterling itself was soon to be forced from it), a policy of balanced budgets at much lower levels and severe reductions in salaries and wages. This proposal would have meant a reduction in national income of at least 50% (the actual reduction between 1929 and 1932 was about 30%) and was so deflationary that any plan less so was able to be described as the "middle way."

The technical advisers of the Australian governments resisted the most stringent deflationary proposals. They pointed out that the "first problem of economic readjustment is to distribute the first loss of income fairly among all classes according to their capacity to bear the burden" ("A Plan for Economic Adjustment," a memorandum prepared by D. B. Copland, L. F. Giblin and E. C. Dyason [1930]). Their recommendations included depreciation of the currency to restore real income of exporters to within 10% of that of 1929; a reduction in real wages of 10%; and a general reduction in all government expenditure of 10%. There was a possibility that the first recommendation might have a nondeflationary effect as foreseen, but the other proposals reflected the assumption that a loss of national income had been suffered and should be borne equitably.

In Oct. 1930 the Lang Labor government was elected in New South Wales. In January the commonwealth arbitration court ordered a reduction of 10% in the basic wage, and in February the exchange rate, after its free depreciation, was fixed at £A130 = £100 sterling but by December it had become £A125 = £100 sterling. In May 1932 the Lang government was dismissed by the governor for allegedly unconstitutional procedure, and the depression had reached something like rock bottom. Unemployment had reached more than 500,000 persons, shops were empty, houses sought tenants at almost any rent, factories were idle, families were broken up and bankruptcy was common. During the year government expenditure was cut by more than 10%; even pensions, low as they were, were cut below subsistence level. National income was 30% below 1929 and average unemployment in industry was 29% of the labour force.

Although bank advances and government securities increased after 1931, the increase was almost entirely in government and municipal securities held. Advances did not really begin to increase until 1934, remaining at £A249,000,000 in 1932, £A253,000,000 in 1933 and £A255,000,000 in 1934. The commonwealth government in 1931 proposed the raising of £A18,000,000 from the Commonwealth bank, £A12,000,000 for public works and £A6,000,000 for a subsidy to wheat producers. The governor of the bank refused to make the money available and the state of law and political climate was such that the bank prevailed over the government.

The policy of the Australian governments during these years of depression is sometimes quoted as a significant departure from the normal method of deflation. On the contrary, it is clear that the Australian depression was dealt with by the normal method of income and, therefore, by cost reduction, calculated to bring the Australian economy into line with similar movements overseas. Only when this had gone sufficiently far did recovery commence and then it was almost entirely the result of private business initiative. The depression in Australia served again to emphasize how much the country was dependent upon external economic conditions and how little it had departed from the market economy, not that it had acquired any significant national economic independence or any means for planned, positive economic action.

World War II.—Australia followed within a few hours Great Britain's declaration of war on Germany on Sept. 3, 1939. As in 1914, no voice in parliament, or of influence elsewhere, was raised against it. In Sept. 1939 few of Australia's resources, although substantially more than in 1914, were devoted to war. The economy had developed sufficiently to make its rural and manufacturing production a substantial factor. In 1939 Japan was an ally of Germany and many Australians felt that it would not be long before it came into the war. Two issues were involved which, even if not clearly recognized at the beginning, were likely to make war policy contentious—first, whether service should be in the armed forces or in industry and in what proportions and, second whether Australian armed forces should be used in Europe and the middle east or in the Pacific.

In May 1940, very soon after the appointment of a commander in chief, a director, with almost dictatorial powers, was appointed to organize industry for war production. Training of the armed forces was extended and before the end of 1939 Australian forces left for the middle east. In Sept. 1940 a general election gave the Menzies administration a renewed but slight majority. During 1940 Australian forces were engaged in the Mediterranean and Italian Cyrenaica, and in 1941 in Greece, Crete and the western desert, where Tobruk was held for eight months after surrounding territory had been overrun by Erwin Rommel's German-Italian forces. In these engagements 2,200 were killed and 6,000 taken prisoner.

By Oct. 1941 Australian governments under both R. G. Menzies and A. W. Fadden proved unable to carry on, and a Labor government was formed with John Curtin as prime minister. The Japanese attack on U.S., British and Dutch territory came almost immediately. After losing 22,000 prisoners in Malaya and Indonesia, Australia had very few troops at home trained and equipped to fight. It was decided to transfer two Australian divisions from the middle east and to seek close co-operation with the United States. The Australian government recognized that defense of Australia was its primary duty, and that Britain could not be expected to spare large resources for the Pacific. On March 17, 1942, Gen. Douglas MacArthur transferred his headquarters to Australia.

The Labor party, traditionally opposed to conscription, introduced the most far-reaching control and direction of manpower in history. The Japanese were halted at sea, largely by U.S. forces in the battles of the Coral sea and Midway, and then in New Guinea by Australians at Gona, Buna, on the Kokoda trail across the Owen Stanleys and at Milne bay. Soon the campaign to remove the Japanese from New Guinea and adjacent islands began. By Sept. 1944 Australian forces had suffered 70,000 battle casualties, the air force had lost 12,000 men and the navy 2,500.

The Curtin government, returned with a large majority in Aug. 1943, determined upon the reinforcement of the production line with a net transfer of 57,000 men from the armed forces. With the U.S. forces "island hopping" in their advance toward Japan Australians embarked upon a campaign of isolating and destroying Japanese forces in Bougainville, New Britain, Wewak and Borneo. Atom bombs on Japan in Aug. 1945 brought the war to an end without the need for the completion of these campaigns. Throughout the war the Australian air and naval forces co-operated with the British in the defense of Great Britain, in the air attack on Germany and in naval operations all over the world.

World War I had done much to strengthen Australia as a manufacturing country, but World War II changed it into a highly industrialized one. The circumstances of the war raised Australia to a strength and independence in international relations that changed its role in international affairs for a few years.

Postwar Years.—World War II proved to be not only a substantial military effort by Australia but also a successful economic one. Despite a most significant transfer of manpower and resources from peacetime productive uses (595,740 people were in the armed forces at the end of the war and, probably, another 400,000 were in war work) and then back again in 1946 and 1947 there was no inflation or unemployment and living standards continued to rise.

The Re-establishment and Employment act (June 1945) provided the general pattern of demobilization, re-employment and training. By Feb. 1947 demobilization was completed with the transfer of about 900,000 people from the armed services and

war work. The Commonwealth Reconstruction Training scheme provided for the training of service personnel in 400 different occupations and professions. By Sept. 1948, when the scheme was at its height, 285,000 ex-service men and women had been accepted for benefits and 227,000 were actually in training.

By 1948 it was apparent that the main postwar problem was to be inflation, not, as had been anticipated, unemployment. The need for reconstruction in many countries and, soon, the "cold war" meant a high level of demand for goods of all kinds. Inflation came to Australia through high prices for exports. As earlier with unemployment, the danger of inflation was at first overestimated. The Labor government, led after Curtin's death in 1945 by J. B. Chifley, held on firmly to controls, while the Liberal-Country party in opposition raised the cry of freedom, self-interest and profit. Although the Labor government could claim to have established a "welfare state" between 1944 and 1949, it had not, by the latter year, made much change in the distribution of income. Financial activity, in general, followed wool prices, and government spending was high. Wage rates were automatically adjusted for price increases every three months. With little in the way of a positive policy, nothing to redress the balance for those of its own supporters who had lost from inflation, and a controversial issue in the 1947 Bank Nationalization act, the government unsuccessfully went to the polls on Dec. 10, 1949. Its defeat brought in a Liberal-Country government headed by R. G. Menzies, with a policy of decontrol. Application of this policy, however, coincided with a vast increase in export money income. Prices rose rapidly and overseas funds soon fell as imports rose even more rapidly than exports. In the resulting crisis the "no control" Liberal government turned to rigorous control of imports. But, except for a short period, almost full employment was maintained. Economic production began to increase and to diversify durable consumption goods. This was sufficient, even when automatic wage adjustment was abolished, to allow people to pay more attention to the government's cry of "Communists" than to inflation.

The Liberal government alleged that the danger from Communism was so great that the Communist party in Australia must be outlawed and Communists debarred from holding certain offices or positions. A referendum to permit this was defeated in 1951, but the issue was kept alive by the appointment of a royal commission on espionage following the defection of a member of the Soviet embassy in Canberra in 1954. A splinter group set up inside the Labor party in 1955, under the influence of the political wing of Catholic Action, proceeded a considerable distance toward its objective of capturing that party in Victoria to use it in its fight against Communism, but its success produced a split both in the party and in the church, which reduced the electoral strength of the Labor opposition throughout Australia. Favourable economic circumstances, fear of Communism and the weakening of the Labor party all contributed to further Liberal party victories in the general elections from 1951 to 1966. Immediately after World War II, Australia had looked primarily to the United Nations for security, and supported those countries in Asia seeking political independence. The change of government in 1949 from Labor to Liberal-Country party had brought a change of emphasis, which derived from the new government's antagonism toward Asian revolutionary nationalism. As it became more apprehensive of the growing independence of nations in Asia, the Liberal-Country regime placed greater stress on close alignment with the United States and with Asian anti-Communist governments.

The ANZUS treaty (Sept. 1951) between the United States, Australia and New Zealand, an offset to Japanese rearmament, was the first attempt to formalize these relations. The establishment in Sept. 1954 of the Southeast Asia Treaty organization (SEATO) was aimed at checking the growing Communist influence in the area. Australia took part in the Korean War, gave assistance in South Vietnam and sent troops to Malaya. There was no claim that any of this was done under any of the treaties. However, the result was that Australia began to take sides with one Asian country or interest against another, and for the first time, since perhaps 1938, the possibility of an external threat to Australia became a reality. Indonesia's desire to obtain West New Guinea (West Irian) from the Netherlands provided the Australian government with a delicate diplomatic problem.

The formation of the federation of Malaysia and Indonesian objections to the inclusion in the federation of Sabah and Sarawak led to Indonesian hostility toward Malaysia (expressed in the Indonesian government's policy of "confrontation") and forced Australia to choose between one Asian country and another in a dispute. For a time Australian troops were openly committed to combat against Indonesia, but the ending of the "confrontation" (Aug. 11, 1966) was followed almost immediately by the withdrawal of the Australian troops that had been stationed in Sabah. Similarly, allegations by the United States of aggression by North Vietnam resulted in an agreement by Australia to send troops to fight in South Vietnam.

Early in 1966 Sir Robert Menzies, who had held office as prime minister continuously since 1949, resigned and was succeeded by the former federal treasurer H. E. Holt. In Feb. 1966 a decimal system of currency was introduced in Australia.

Australia's population (about 11,500,000 by the late 1960s) and economic production continued to grow so that in industrial capacity the country became the strongest in southeast Asia. After World War II, immigration proved of great significance—more than 1,250,000 people entered Australia at rates seldom exceeded by any country at any time. Not only did this contribute much to the strength of the nation, but it also made an important difference in its composition. From being predominantly British, Australia became a nation with increasingly large numbers of people from other European countries, thereby creating a more colourful and diverse community. (J. F. C.)

IV. POPULATION

The total population of the commonwealth of Australia in June 1966 was 11,544,691. The previous census, taken on June 30, 1961, had returned a total population of 10,508,186.

Population of Australia

States and territories (with capitals in parentheses)	Area in sq.mi.	Population			
		1961 census	Density per sq.mi.	1966 census	Density per sq.mi.
States					
New South Wales (Sydney)	309,433	3,917,013	12.7	4,235,030	13.7
Queensland (Brisbane)	667,000	1,518,828	2.3	1,661,240	2.5
South Australia (Adelaide)	380,070	969,340	2.6	1,090,723	2.9
Tasmania (Hobart)	26,383	350,340	13.4	371,217	14.1
Victoria (Melbourne)	87,884	2,930,113	33.3	3,217,832	36.6
Western Australia (Perth)	975,920	736,629	0.8	835,570	.85
Territories					
Australian Capital (Canberra)	939	58,828	62.6	95,913	102.1
Northern (Darwin)	520,280	27,095	0.05	37,166	.07
Total	2,967,909	10,508,186	3.5	11,544,691	3.9

These figures were exclusive of full-blooded aborigines, estimated to number 40,081 in 1961 and found principally in Western Australia, the Northern Territory, northern Queensland and South Australia. There are signs that the aborigines are increasing in number. All but an estimated 4,000 live in or near settlements. In addition to the full bloods, there were, in 1961, 39,172 classified as half-caste aborigines. Most of these live in settled areas and are included in the total population figures above. Before European settlement the aboriginal population of Australia and Tasmania may have numbered, according to varying estimates, from 150,000 to 350,000.

Apart from aborigines the population is almost entirely of European stock, 99.1% being described at the 1961 census as of European racial origin, 0.4% aboriginal half-caste and the rest Asian (mainly Chinese) and Polynesian. Immigrants to Australia since its foundation have been overwhelmingly of British descent. Before 1946 the only other European groups that contributed significant numbers were Germans, Italians and Greeks. Between 1947 and 1961 the immigrant population increased from 733,000 to 1,779,000, of whom 228,000 were from Italy, 109,000 from Germany, 102,000 from the Netherlands and 77,000 from Greece. Non-British subjects constituted 5% of the population in 1961.

Between 1947 and 1964 Australia's population increased by 3,556,000, or nearly one-half, at an average annual rate of 2.4% (*cf.* United States 1.7%, India 1.9%, United Kingdom 0.5%). To this rapid rate of population growth a relatively high rate of natural increase (1.4%) contributed three-fifths, an ambitious immigration program two-fifths. In this postwar period the birth rate averaged about 23 per 1,000, compared with 17 per 1,000 in the depression years of the 1930s.

The death rate continued to fall in Australia, the expectation of life at birth in 1953–55, 67.14 years for males and 72.75 years for females, being among the world's highest. In 1947, with 1,004 males per 1,000 females, the sexes were very nearly in balance. The postwar wave of immigration, like earlier waves, tended to raise the male proportion, which reached 1,017 males for 1,000 females in 1964. The male proportion was higher in rural than in metropolitan areas and higher also in the states and territories with small populations than in Victoria and New South Wales.

With 3.8 persons per square mile, Australia remained the least densely populated of the continents. Even Victoria, the most densely populated state, had only 33 persons per square mile in 1961. By comparison, Europe (excluding the U.S.S.R.) had an estimated density in 1961 of 224, Asia (excluding the U.S.S.R.) of 163, North and Central America of 28, Africa of 22 and South America of 20. At least 10,000,000 of the total population of 10,508,186 were found in the better-watered areas of nontropical Australia. Tropical Australia (northern Queensland and parts of Northern Territory and Western Australia) had a population of less than 400,000. The area south of the tropics with a rainfall exceeding 15 in. (381 mm.) annually amounts to about 560,000 sq.mi. (1,450,000 sq.km.) (less than one-fifth of the country). Beyond this area, apart from mining towns, the density reached one person per square mile only in irrigated areas of the Murray and its tributaries and on wheatlands in South Australia, Western Australia and Victoria (mallee district).

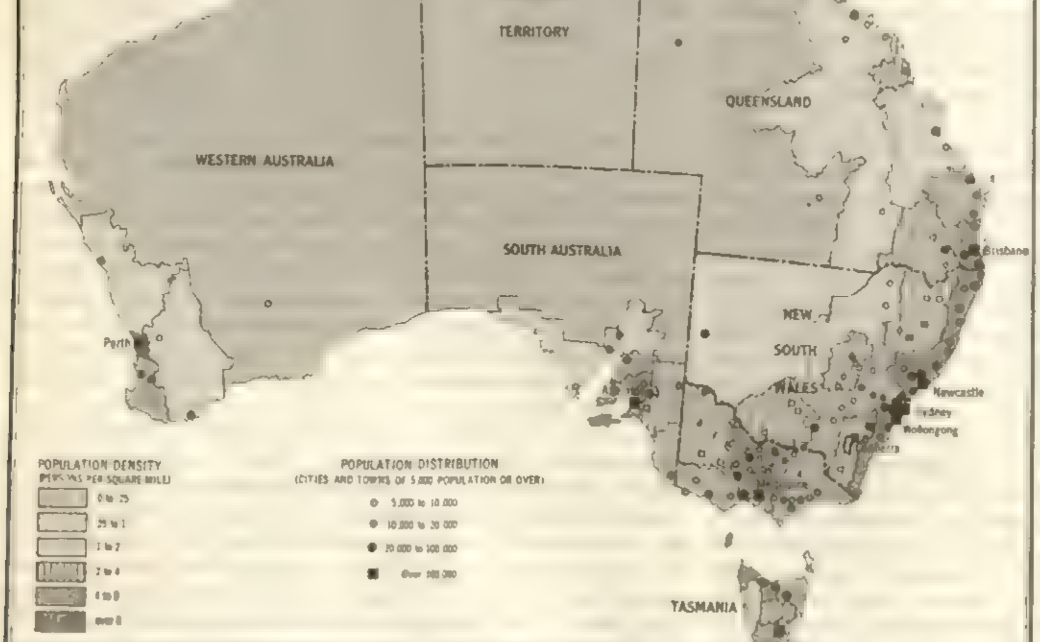
A feature of the population distribution was the heavy concentration in the capital cities. With 59% of its people in cities with more than 100,000 (1961 census), compared with just over 40% for the United Kingdom, about 30% for the United States, nearly 40% for the Federal Republic of Germany and nearly 30% for Japan, Australia had a more urbanized population than any other country in the world. Apart from the state capitals (1961 metropolitan population: Sydney 2,183,388, Melbourne 1,911,895, Brisbane 621,550, Adelaide 587,957, Perth [including Fremantle] 420,133 and Hobart 115,932), there were only 2 cities of more than 100,000 (Newcastle and Greater Wollongong) and 23 others of more than 20,000, including the rapidly growing national capital, Canberra, whose population had reached 56,449.

The high urban proportion is reflected in the industries in which the economically active population is engaged. Agriculture, fishing and forestry employed only 10.9% of the working population in 1961, while manufacturing (including public utilities) accounted for 29.2% (*cf.* United States, 1950, 25.1%), commerce and finance for 19.6% and professional and public services for 13.7%. Rural industries absorbed a diminishing proportion of the working population during this period, while the share taken by manufacturing rose continuously except during the depression of the early 1930s.

Conditions of Settlement.—Climate has been and remains the governing influence on settlement. The size of the continent stretching from the tropical north to the temperate latitudes of Tasmania, provides great variety of climatic conditions. But opportunities are seriously limited by the continent's geographical position and topographical structure. The fact that its greatest extension is east-west in subtropical latitudes, combined with the flatness of the whole land mass except along the eastern coast line, where a mountain range lies athwart the major rain-bearing winds, results in an immense area of insufficient and irregular rainfall in the centre and western half of the continent. Lack of high land in the tropics, where it might mitigate temperatures, and the location of most mountainous parts in temperate latitudes, where the land would be more valuable were it low, are further impediments to settlement.

These basic features go far toward explaining the peripheral character of settlement along the eastern, southern and western coasts of the continent. Although there is strictly no "dead heart" —the flourishing little town of Alice Springs lies right in the centre—it is only in the southeastern corner, with its regular, good rainfall, that intensive settlement has moved far from the coast. Elsewhere, the interior remains at best a barely populated area comprised of vast pastoral stations, with only widely scattered mining centres.

It is difficult to feel that basic geographical or climatic features account for the other major characteristic of settlement in Australia—the concentration of more than half the population (1961 census) in the metropolitan areas of the six capital cities. There historical, social and economic factors have probably been more influential; for instance, the fact that its people have been drawn from the most urbanized country of Europe, the early bias toward a large role for government given by its historical origin in convict



COMMONWEALTH BUREAU OF CENSUS AND STATISTICS, CANBERRA, AUSTRALIA

FIG. 7.—POPULATION DENSITY AND DISTRIBUTION IN AUSTRALIA: BASED UPON 1961 CENSUS

colonies, and the preponderant influence of extensive pastoral production in its economic development, which has discouraged intensive farming and at the same time raised incomes to levels at which demand for the products of secondary and tertiary industries has been high.

Immigration.—Immigration into Australia has generally been a major concern of governmental policy. Until the middle of the 19th century the issue of convict transportation versus free immigration dominated the scene. Thereafter immigration policy was characterized by three main features: alternating support for and opposition to large-scale immigration, closely linked to conditions of domestic prosperity; strong preference for immigrants of British origin; and, from the later decades of the 19th century, exclusion of coloured immigrants.

The main phases of large-scale immigration were as follows: 1852–58, 1876–91, 1909–13, 1921–25 and 1948– . Each phase corresponded to a period of domestic prosperity and rapid economic development. This prosperity and the consequent labour shortage attracted immigrants and induced governments to assist and encourage immigration, while large-scale immigration, in turn, stimulated domestic economic activity, chiefly through the actual and anticipated demands of immigrants for houses and other capital equipment.

Government assistance generally concentrated on payment of the whole or part of immigrants' passages to Australia, though in the post-1948 phase in particular the official immigration program included activity in the selection, transport, settlement and care of migrants.

Up to 1920 assisted migration was controlled entirely by the various state governments. In that year the commonwealth government assumed responsibility for the recruitment and transport of immigrants. In 1925 it entered into an agreement with the British government for the large-scale settlement of British migrants in Australia. While these schemes were generously conceived, the results were disappointing. Immigration reached a fairly high level during 1921–25, but after 1927 a decline set in and the depression years after 1929 saw a net loss of population, resulting from extensive emigration from the commonwealth. After a brief revival in 1938 and 1939, World War II put a stop to migration until 1945.

Then a new phase began. Optimism about the economic future of the country, coupled with a general feeling that the war had shown the danger of Asian attack to which an underpopulated white continent was exposed, stimulated a determined effort to develop a large immigration program. The temporary availability of large numbers of potential migrants in the unsettled conditions of postwar Europe added a further incentive. A separate department of immigration was established in 1945, led first by a Labor and then by Liberal ministers who shared an almost crusading zeal for the immigration program. Under an agreement with the British government, a new scheme for free passages for British ex-service men and women and assisted passages for other British migrants came into operation in March 1947; by June 1959 it had brought 322,000 migrants into the country. During 1947–52, 170,000 refugees, mainly Latvian, Lithuanian, Estonian, Polish and Yugoslav, were brought from the displaced persons' camps of Europe under agreement with the International Refugee organization. Assistance was also given to certain categories of European ex-servicemen and U.S. veterans. In addition to assisted migrants under these official schemes, thousands of British and non-British migrants went at their own expense. In 1952–53 Australia negotiated agreements with the Netherlands, Italy, the Federal Republic of Germany and the Intergovernmental Committee for European Migration (with respect to migrants from Trieste, Greece and Austria), involving joint assistance toward cost of passages by the governments concerned and selection of migrants according to employment opportunities in Australia. In the early years of the official assisted passage schemes, non-British migrants assumed an obligation to work for two years in public construction or other work assigned to them, but this requirement was later dropped. The emergence of some unemployment in 1952 reinforced widespread doubts that had developed earlier on other grounds about the ability of the economy to absorb immigrants at the 1949–52 rate. As a result of a government decision the rate of intake fell to 75,000 in 1953 but exceeded 100,000 in every subsequent year in keeping with the aim of maintaining net annual migration as nearly as possible at 1% of the population. In 1964 it was decided to extend to the countries of the middle east the areas from which the commonwealth would actively seek new settlers.

Meanwhile, the "white Australia" policy, officially termed "restricted immigration policy," remained a cornerstone of the immigration program. It arose gradually during the second half of the 19th century from fears of competition by Chinese immigrants and by imported labour from the Pacific islands. While economic support for it was centred in the labour movement, the policy was supported by all classes on both social and defense grounds.

However, after 1950 there was increasing discussion of its compatibility with Australia's need to live on good terms with its Asian neighbours. While the "white Australia" policy still enjoyed widespread public support, there was demand in some quarters for quota schemes. The "dictation test" that had been used to exclude coloured and other undesired immigrants was replaced in 1959 by an entry permit system, and in the early 1960s this was being administered in an increasingly liberal manner. Coloured students, tourists and businessmen had been admitted, since 1905, under temporary permits, and after 1945 large numbers of Asian students were encouraged to study at Australian universities and schools. (H. W. A.; A. J. Ro.)

V. ADMINISTRATION AND SOCIAL CONDITIONS

The Australian political system is closely modeled on that of Britain, the principal novelty being the federal division of functions between the national (commonwealth) and regional (state) governments. In this respect it resembles the federal system of the United States. Although the commonwealth government has been in existence since 1900, the six state governments (Queensland, New South Wales, Victoria, South Australia, Western Australia and Tasmania) remain responsible for police administration, education, hospitals, public housing, land settlement, irrigation and an ambitious range of fuel, power and transport undertakings.

More complex arrangements involving both levels govern the regulation of industrial conditions and standards, agricultural marketing, public health, and the courts and legal system. Fiscal resources, however, are highly centralized, and state governments depend for two-thirds of their revenue on commonwealth grants. Both commonwealth and state governments are liable to check by the high court, which pronounces upon the constitutionality of statutes. Local government in Australia is not strongly developed, and local authorities (of which there are roughly 1,000) are primarily concerned with road making.

In addition to the state governments there are two federally controlled territories—the extensive but sparsely populated Northern Territory and the small Australian Capital Territory. The latter includes the federal capital of Canberra. The federal legislature, like that of the United States, consists of two houses: the house of representatives, whose membership is drawn from the states according to their population, and the senate, in which all states are represented equally. Australia follows the British system of placing executive powers in the hands of a cabinet, headed by a prime minister and responsible to the lower house of the legislature. Members of the federal judiciary are appointed by the government, hold office for life and have a high degree of independence. The head of the judicial system is the high court of Australia.

The various public services are of somewhat uniform design despite the fact that each is quite self-contained. Officials are organized in ministerial departments free from political interference in recruitment and promotion and enjoy permanent tenure. Egalitarian sentiment for a long while successfully opposed direct recruitment of university graduates to administrative positions, which were filled by promotion from below. Extradepartmental boards are widely used for regulatory and advisory services,

as well as for work of a commercial or industrial character. A genial pluralism allows major interests a preponderant influence in domestic policy matters: farmers in marketing, manufacturers in the tariff, trade unions in wage fixation and the professions in occupational registration.

Living Conditions.—Since 1945 Australians have enjoyed conditions of remarkable prosperity, though an acceleration of inflation in several periods has caused the benefits of this prosperity to be awkwardly distributed. Throughout these years governments in Australia had little trouble with their postwar promises to maintain high and stable levels of employment. The distribution of income, which had long been one of the most egalitarian in the world and which wartime developments carried still further, has tended since the early 1950s to become more unequal, though labour's share in the national income has remained stable at 55% to 60%. Taxation is at American rather than British levels, almost half is still indirect and income taxation has become less steeply progressive. International comparisons of living standards put Australia among the richest eight or nine countries in the world—health statistics in particular being extremely favourable. The 40-hour working week was adopted in 1948.

Welfare Services.—Although Australian governments were early pioneers in the field of welfare legislation, measures to promote social security were somewhat spasmodic and limited up to World War II. Providing a living wage was the initial policy in this field. But as time went on, Australian governments supplemented this basic goal with additional social services. Before 1939, however, social services developed very unequally in different parts of the country and had not in total extended very far.

New benefits introduced during World War II and in the immediate postwar years in an effort systematically to meet causes of income deficiency included child endowment (family allowances), widows' pensions, unemployment and sickness benefits, hospital benefits, pharmaceutical benefits and free drugs, allowances for wives and children of invalid pensioners, funeral benefits, benefits for tuberculosis sufferers and their dependents and home nursing services. Expenditure on welfare services has not risen greatly as a proportion of the national income under full employment conditions.

The failure of the federal Labor government to win the support of the medical profession for its free medical and dental services left a serious gap in the security edifice, only partly filled by the introduction by the succeeding Liberal-Country party coalition government in 1951 and 1952 of voluntary insurance schemes for medical and hospital expenses. Nearly 70% of the population is insured for medical benefits. In 1964 the federal government paid £A12,000,000 to help them meet their doctors' bills. Many of the uninsured are covered by the pensioner medical service or by repatriation benefits paid to ex-servicemen.

Apart from the health services, all Australian welfare benefits are noncontributory, being paid from consolidated revenue. Most, however, and in particular the age pension, are only paid subject to a means test.

Education.—Primary and secondary education in Australia is mainly the responsibility of the state governments: they educate three-quarters of all children of school age. About one-fifth go to Roman Catholic schools, and the remainder to other private schools (principally Protestant owned); neither type receives public financial assistance on any scale. The state schools are notable for their highly centralized administration and their freedom from popular and political control. Although the compulsory school-leaving age has not everywhere been raised to 15, a very high proportion of pupils do in fact remain on voluntarily, though the enrollment ratios of the age groups 15–19 and 20–24 years in Australia compare unfavourably with those of many other countries. Expenditure on education as a proportion of gross national product places Australia 15th on international lists. The problem of reaching children in remote and sparsely settled areas led to a number of interesting experiments in correspondence teaching, area schools and school broadcasting. The Australian Broadcasting commission's "Kindergarten of the Air" was an original venture that proved highly successful. Kindergartens, which spread widely only after the 1940s, are a municipal responsibility. Technical education, including agricultural training, is highly organized, and children have in practice a free choice between three types of secondary education—technical, academic and general.

There is a well-established university in each of the seven capitals, the universities of Melbourne and Sydney being among the oldest in the Commonwealth of Nations outside of the U.K. Both cities have set up second universities to cope with increasing student numbers. A purely research institution, the School of Advanced Studies of the Australian National university, Canberra, began work in 1947 in the fields of medicine, the physical sciences, the social sciences and Pacific studies.

The Australian Universities commission set up in 1959 was given wide responsibilities in the field of university development, matching the increased and now predominant federal contribution to university finances.

Substantial equality of opportunity in education in Australia has, however, been only a late achievement, and the proportion of university graduates educated in private schools has greatly exceeded these schools' share in the total school population. Commonwealth scholarships for undergraduate (and postgraduate) study for most students with the requisite ability have improved matters, and the main neglect of talent is now at the secondary level. All states have established adult education services, in some cases building on privately developed workers' educational associations.

Health.—All levels of government—federal, state and municipal—are concerned with public health; the municipalities function largely as agents for the administration of state government policies in this field, the commonwealth government's concern being with the administration of benefits and medical research. An example of work involving all three levels was the Salk polio vaccination campaign, in which the commonwealth procured and paid for the serum, the states organized the distribution and provided doctors, and the local authorities provided premises and publicity.

Each state department of health is responsible for infant welfare and school medical and dental services, for the treatment of infectious and contagious diseases and tuberculosis, for industrial hygiene programs, for the maintenance of food and drug standards, for public hospitals and the regulation of private hospitals and for mental hospitals. The National Health and Medical Research council, a committee of senior commonwealth and state health officers and medical specialists, advises the federal and state governments on public health policies and supervises the distribution of the main federal grants for medical research. The commonwealth government maintains a large number of specialist medical research institutions, among the most notable being the Commonwealth Serum laboratories, the Commonwealth Acoustic laboratories, the Commonwealth Bureau of Dental Standards, the School of Public Health and Tropical Medicine, the Institute of Child Health, the X-ray and Radium laboratory and the Australian Institute of Anatomy.

Housing.—While both commonwealth and state governments assisted house purchases and some states had slum clearance schemes, housing was not widely regarded before 1939 as a public responsibility. The 1939–45 shortage and the pressure of postwar migration (at the peak of the program Australia was attempting to absorb a population increase of 3% annually including natural increase) brought public housing to the forefront of official preoccupation. In 1945 the commonwealth undertook the subsidizing of state-built houses to the order of about 10,000 each year. The renewal of the agreement in 1957 with a change of commonwealth government eliminated rent subsidies and needs tests and removed the emphasis on rental housing but maintained the level of output.

The emphasis on home ownership in Australia is remarkable, approximately 63% of the dwellings being owned or in process of purchase by occupiers. Houses are of reasonably high standard, with an average of 1.4 rooms per person in all residences. One of the most striking features of housing after World War II was

the high proportion of new houses that were owner built. In 1950 both Sydney and Melbourne prepared town plans, for unregulated sprawling had begun to impose serious difficulties on the development of public utilities.

Justice.—The Australian legal system is derived from, and still closely follows, that of England. Australian courts pay high regard to English judicial decisions, and common law supplements law made by parliaments and their delegates. Each state has a supreme court and a system of subordinate courts with a variety of names. Judges are appointed by executives, but convention secures them a high degree of immunity from executive interference. Juries are used in the more serious types of criminal prosecutions; they are not used in petty criminal courts, and only to a limited extent in civil cases. Unpaid justices of the peace, usually without legal training, are extensively used in subordinate courts.

The federal high court is a general court of appeal from the state supreme courts, as well as being the court of original jurisdiction for cases involving constitutional issues. The federal constitution gives a limited right of appeal from the high court to the privy council, but the leave of the high court itself is necessary and is rarely given (only a handful of major cases on the interpretation of the federal constitution has gone to the privy council since federation).

The growth of administrative tribunals in Australia has been steady; it has been estimated recently that three-quarters of all cases are heard outside the courts.

Defense.—Subject to the authority of the cabinet, the federal minister and department of defense are responsible for the formulation and general application of a unified defense policy. Within that policy separate ministers and departments of the navy, army and air are responsible for the administration of the services, and the department of supply for meeting the supply and production requirements of the services. The department of defense maintains three major policy-making bodies: (1) the defense committee, comprising the secretary of the department of defense and the chiefs of staff of the three services, which advises on policy as a whole; (2) the chiefs of staff committee, which is responsible for strategic appreciations and military plans, the control of special forces and control of war operations if a commander in chief is not appointed; and (3) the joint war production committee, which relates industrial war potential to strategic plans.

The numerical strengths of the three services, including citizen forces, in 1964 were navy 19,000, army 54,000 and air force 18,000. Expenditure on war and defense has averaged about 16% of expenditure by public authorities.

The government's three-year program of defense announced in 1964 would raise total defense spending by almost 50%. It introduced a selective compulsory training and service scheme for men aged 20. The new defense program would also hasten the modernization of the army and the further re-equipment of the navy and air force. In all three services the developments were primarily identified with a defensive role, but they could provide an offensive potential against an aggressor in southeast Asia if the need for one should arise. (A. F. Ds.)

VI. THE ECONOMY

Important changes took place in the structure of the Australian economy during and after World War II. The share of the gross national product earned by the agricultural and mining industries (primary) showed a relative decline, while a much greater proportion could be traced to manufacturing and building (secondary and tertiary) industries. There were similar changes in the distribution of labour. Employment in the primary industries declined relatively (although growing absolutely), whereas employment in the manufacturing and building industries grew both absolutely and relatively.

The importance of the pastoral and agricultural industries does not lie in their direct contributions to national wealth but in their export earnings. Fluctuations in world prices for primary products cause considerable variations in export earnings, but as the reserves of exchange have been built up the internal Australian economy has become less susceptible to swings in the level of business activity in the world at large.

Changes in the structure of the economy are also reflected in the composition of Australia's imports. A decreasing proportion consists of elaborately transformed articles, while an increasing share is made up of raw materials for Australian factories. Thus, the traditional view of Australia as a predominantly agricultural and pastoral economy, exporting foodstuffs and raw materials and receiving in return elaborately manufactured goods, is outmoded; an increasing proportion of Australia's requirements in goods and services is now being supplied from local sources.

A. Production

Agriculture.—*Environment and the Use of Land.*—The use of land in Australia is influenced by both the physical environment and the socioeconomic environment. Among the factors making up the physical environment are the topography, soils, vegetation and—of overriding importance in this continent—the climate, particularly the incidence and reliability of rainfall in relation to the rate of evaporation (see *Climate*, above). Aridity and the distance from markets prevent the commercial use of about 34% of the total land area of Australia; all attempts to introduce stock into this region, which stretches north from the Great Australian bight and includes large portions of South Australia, Western Australia and the Northern Territory, have failed. Another 42% of the land area, to the north, east and west of this arid zone, receives only enough rain to support cattle and sheep. Less profitable than sheep, cattle are found in the drier interior tracts, in the hot humid areas in the north and in humid upland and coastal areas in the southeast.

Elsewhere sheep grazing predominates except in areas suitable for crops. (For land use map *see* Agriculture.) The remainder, about 24%, receives sufficient rainfall to support agriculture, but much of this area is mountainous or has poor soils. Thus, the area suitable in all respects for the cultivation of crops is no more than 8%, but a considerable part of this is used for intensive sheep and cattle raising and dairy farming. Only a little more than 1% is actually under cultivation.

There have been many changes in the socioeconomic environment since the beginning of the 19th century. For example, mechanization made possible the extensive cultivation of wheat; refrigeration encouraged the development of beef production to supply northern hemisphere markets; and irrigation, particularly around the Murray river and its tributaries, permitted the growth of intensive mixed farming. At any given time, therefore, local and world market conditions, the accumulation of wisdom gained from practical experience and the state of technology considerably influence the actual use made of land within the broad limits set by the physical environment.

Special mention must be made of floods and droughts, pests and diseases. In northern areas of Australia, monsoonal summer rains bring road transport to a standstill and close stock routes, whereas during the winter dry season watering points are essential on properties and stock routes. Over most of the western half of Queensland extending into northern New South Wales, northeast South Australia and the southeast of the Northern Territory, water for stock can be obtained from the Great Artesian basin (see *Artesian Water and Irrigation*, above). In general this underground water is too high in mineral content for irrigation purposes. The presence of carbonate of soda, for instance, makes a hard pan of all but the sandiest soils. In southern areas winter rains cause flooding in some parts of the eastern coastal plain, while the relatively dry summer makes hand feeding or the movement of stock to more favoured areas a common practice in some regions of the inland pastoral zone.

Australia is well endowed with natural fodders; saltbush is nutritious and drought resisting, and a wealth of ephemerals, chiefly composites and grasses, are found after rains. In many parts of the extensive pastoral country the problem is to maintain even the present low carrying capacity by better management (improved watering, fencing, resting pasture and conservative stocking). In climatically more favoured zones pasture improvement

has been achieved by sowing introduced species and better strains of plants and by correcting soil nutrient deficiencies. The area under sown grasses and clovers increased substantially. Introduced species include perennial rye grass, cocksfoot, white clover, paspalum, Rhodes grass and, of particular importance, subterranean clover. Most Australian soils are deficient in nitrogen and phosphate, and the joint use of legumes, such as subterranean clover, and superphosphate and trace elements, such as copper, zinc and molybdenum, has done much to improve pastures in southern areas.

A wide range of plant and animal pests and diseases exists in Australia. In the inner more sparsely populated areas dingoes still cause heavy losses (up to half the calves and lambs born in some districts). Various control methods have been adopted, such as barrier fences, traps and poisoned baits, and a bounty is paid for each dingo killed. Rabbits were again becoming a serious pest by 1960 even though their numbers had been greatly reduced early in the 1950s by the use of the virus myxomatosis. Major pests in the pastoral industry are the blowfly, which attacks sheep, and the cattle tick, the monetary loss from which has been estimated at £A10,000,000 annually. Agricultural crops are subject to a wide range of insect, fungal, bacterial and virus diseases.

Sheep and Wool.—Sheep constitute the most important single element in the Australian pastoral industry. After 1947 (following a severe drought in 1945) there was a continuous upward trend in sheep numbers. These amounted to 160,000,000 in 1963 (17% of the world total) and produced about 30% of the world's wool.

There is a direct relationship between rainfall and sheep density. Densities are greatest in areas receiving from 15 to 20 in. (381 to 508 mm.) of rainfall each year. Below 15 in. the density decreases, but above 20 in. the density remains fairly constant until 30 in. (762 mm.), when sheep give way to cattle. Merinos predominate in areas having less than 20 in. annually, but relatively dense populations of crossbreds and British breeds are found in areas that receive up to 30 in. in temperate to cold climates. Sheep seem to do best when the average annual rainfall is between 15 and 25 in. and average temperatures are between 55° and 70° F. (12.7° and 21.1° C.). There are, however, dense sheep populations where midwinter average monthly temperatures are below 55° F. (coupled with relatively high rainfall), such as in the highlands of southeastern Australia, and where midsummer temperatures are above 70° F. (coupled with relatively low rainfall), such as in central Queensland. However, sheep are not run in such areas as the eastern coastal fringe and the far north, which experience both high rainfall and high temperatures.

A threefold specialization occurs within the sheep industry. First, in the semiarid areas with unreliable rainfall, emphasis is placed on the production of fine wool; most of the sheep are Merinos because of their ability to survive unfavourable conditions of heat and humidity and because of the high value of their wool. Second, in the wheat and sheep areas, which have higher and more regular rainfalls, there is a tendency to run dual-purpose crossbred animals producing wool and meat of good quality for local and overseas markets. Third, in southern Australia, with high rainfall and reliable seasons, the emphasis is on fat lamb and mutton production, with coarse wool as a by-product. The Merino is the dominant breed in most areas followed by comeback (Merino crossed with any English breed and offspring crossed back to Merino), crossbred and other. Carrying capacity reaches one sheep per acre on natural pastures throughout fairly large areas in the higher rainfall country but falls to one sheep per 30 ac. in the drier areas; country with a lower carrying capacity than this is generally used for cattle, which can seek fodder farther away from watering places.

The size of Australia and the wide variations in climate permit shearing to continue all the year round. The quality composition of the Australian clip is: 70s and finer, 2.7%; 60s to 70s, 72.0%; 50s to 60s, 22.7%; below 50s, 1.0%; and oddments, 1.6%. (The quality, 60s, etc., is a measure of the fineness and texture of wool for spinning purposes; broadly, it means the number of hanks of yarn, each 560 yd. long, that can be spun from one pound of combed wool; *i.e.*, wool of 60s quality will produce 60 such hanks.) Australia is particularly well suited climatically for the production of extra fine Merino fleeces and supplies about one-half of all Merino wool. After being graded, baled and transported to selling centres in the capital cities and main country towns, the wool is sold at open auction to buyers from all over the world. The annual production of wool in 1963–64 on a greasy equivalent basis exceeded 1,750,000,000 lb., of which (including raw wool, woolen tops, and woolen and worsted yarns) about 93% was exported, mainly to Japan, the United Kingdom, Italy and France. The average annual export of wool was about 35%–38% of all merchandise exports. The production (carcass weight) of mutton and lamb in 1963 was 594,000 tons.

Beef Cattle.—The Australian cattle industry has not attained a position comparable to that of the sheep industry, and, in general, cattle are found in areas not suitable for other pastoral activities (although most sheep farms have at least some cattle).

About 25% of the beef cattle are found scattered along the eastern and southern seaboards or over parts of the continent having temperate or subtropical climates, and generally only in the rougher country or as a means of controlling rapid growth on sheep properties. The other 75% of the cattle are in the north and northwest of the continent, where the conditions of summer heat, humidity and rank growth are unsuitable for sheep. The cattle there are run on large holdings, chiefly under open-range conditions: the carrying capacity in some areas being as low as one beast per square mile. In the least-favoured areas on holdings commonly exceeding 1,500 sq.mi. (the largest, Alexandria), the main concern is with breeding animals that, on reaching maturity are moved for fattening to smaller holdings in the better districts.

The southern area produces a greater proportion of Australia's beef than the share of the cattle numbers might suggest, because the turnoff is higher than in the north (where most beasts killed are at least four years old), because cattle numbers are increasing at a higher rate and because a considerable amount of beef comes from dairy cattle.

From the northernmost areas cattle move to the export meatworks on the Queensland coast; it is normal for cattle to be driven several hundred miles along stock routes (with watering points 20 and sometimes 70 mi. apart) to railheads and thence to the coast in stock trains. Arriving in deteriorated condition, the cattle are refattened, the average carcass weight of cattle slaughtered at the Queensland export meatworks being about 650 lb. From south-central Queensland the cattle move toward the main local markets in the southeast, 470,000 cattle (the equivalent of about 100,000 tons of beef) move into New South Wales each year and some move from New South Wales into Victoria.

In 1963 beef cattle in Australia totaled about 13,400,000. The important breeds are Shorthorns, Herefords, Aberdeen Angus, Devon and Red Polled, but crossbreeding occurs widely.

Australia consumes 56% of its beef output, cans 6% and exports 38%. The Australian industry was at a disadvantage until it was shown that beef could be successfully transported from Australia to the United Kingdom in a chilled condition. Chilled beef shipments began experimentally in 1932–33, but World War II put a temporary stop to this trade. After the war the export of chilled and frozen beef was resumed.

Dairy Farming.—In the early 1960s there were approximately 5,000,000 dairy cattle in Australia, of which about 65% were dairy cows. The main dairying areas are in the eastern mainland states, particularly Victoria, coastal New South Wales and southeastern Queensland, with smaller concentrations in the western lowlands of Tasmania, in the Mt. Lofty ranges east of Adelaide and south of Perth.

Some cattle, usually those producing whole milk for town supply, are given supplementary rations under stall-feeding conditions and are almost independent of climatic conditions. Some are raised on irrigated areas that generally are used to full capacity for nine months of the year, but most are maintained on dry pastures so that their production is related to climatic variations. Climatic conditions make it unnecessary to house cattle.

Field Crops.—The average acreage under cultivation in the early

1960s in Australia was about 30,000,000, of which 67.9% was cereals for grain, 14.9% green fodder, 10.0% hay, 1.7% industrial crops, 1.0% orchards and fruit crops, 1.4% vegetables for human consumption, 0.4% vineyards and 2.7% various other crops. It has been estimated that after taking into consideration climatic, physical and soil conditions, as well as competing land uses, this acreage is about half the maximum possible for cultivation, although expansion of the area is largely dependent on economic considerations. However, in some areas, notably in Victoria, crop acreage could increase only at the expense of other land uses. The agricultural areas of Australia consist of the wheat belt (which includes areas producing most of the barley, oats and sorghum) and intensively farmed areas where there is fertile soil and good supplies of rainfall or irrigation water.

Wheat.—The greater part of the wheat crop is grown in areas having between 15 and 20 in. (381 and 508 mm.) of rain annually, but the amount of rain between April and October, the growing season, is extremely important. Generally, wheat is sown on cultivated fallow land; to conserve moisture and assist nitrification the land is given an initial plowing in winter or early spring and then kept weed free until the following winter when the crop is sown. More commonly, in districts with adequate rainfall the fallow period is shortened to reduce soil erosion and to allow clover-based pasture to be introduced into rotation. Nitrogenous fertilizers are unnecessary, but superphosphate is applied to most parts of the wheat belt except in northern New South Wales and Queensland, and in some areas trace elements are also added. The area under wheat increased from an average of 14,345,000 ac. (5,805,000 ha.) in the 1930s to 16,900,000 ac. (6,839,000 ha.) in the mid-1960s. Yields increased from 11.8 bu. per acre pre-World War II to 20 bu. per acre in the mid-1960s.

Although Australian yields are low by European standards, output per man is high. This is because of the highly mechanized nature of the industry, the flat to undulating country and the exceptionally dry conditions at harvest time, which allow the grain to be reaped and threshed simultaneously in combine harvesters. The total size of the typical wheat farm is about 1,000 ac. (larger, however, in the drier districts), and the area of wheat per man is 200 ac. About one-third of the Australian sheep population is run on wheat farms; usually they are kept for fat lamb production, but in more remote districts the emphasis is on wool production. On smaller farms the whole area may be under wheat, with the sheep grazing on fallows and stubbles, but on larger properties perhaps only one-quarter of the area may be under cultivation.

Wheat varieties have been developed to suit local conditions, and include early maturing varieties and others resistant to diseases. Of the 45 varieties grown the most popular are Gabo, Bencubbin and Bungalla.

Annual exports of wheat (including flour in terms of wheat) average about 200,000,000 bu. (72% of the crop). In the 1960s China became the main buyer of Australian wheat, taking 35.3% of the exports in 1961–62 and 47.5% in 1962–63. No wheat is imported. Usually 70% of the wheat export is sent abroad as grain, mainly as complete cargoes in charter vessels. Most Australian wheat belongs to the soft white class; and although it has a poor protein quality (9%–10%), its high extraction rate and its whiteness make it popular for mixing with the hard red wheats of North America.

Other Cereals.—Oats and barley occupy approximately 15% and 11%, respectively, of the area sown for cereals for grain.

Oats are produced chiefly in the wheat-growing belt in Victoria, New South Wales, South Australia and Western Australia. Average production in the early 1960s was 64,000,000 bu., of which 28% was exported, chiefly to the Federal Republic of Germany, the Netherlands, China and the United Kingdom.

Barley is grown as a specialized form of cereal production in certain favoured regions of the wheat belt, with South Australia (particularly Yorke peninsula) and Victoria as the chief producing states. Average production in the early 1960s was 41,500,000 bu., of which half was exported.

Maize (corn) is cultivated chiefly along the eastern side of the continent from the Atherton plateau in Queensland south to Victoria. New South Wales and Queensland accounted for most of the 210,000 ac. (85,000 ha.) planted to this crop and for most of the production of 7,000,000 bu. The maize acreage has declined since before World War II and is now mainly a sideline activity on dairy farms.

Grain sorghum was of minor importance before World War II, but after the war the area planted and production both expanded to reach about 380,000 ac. (150,000 ha.) and 9,700,000 bu., most of it being grown in the higher-rainfall areas of Queensland and New South Wales. This crop has tended to replace maize in some of the drier areas because of its superior capacity to withstand low soil moisture conditions and because it can be handled mechanically from planting to harvesting.

Rice is grown commercially mainly in the Murrumbidgee and Wakool irrigation areas of New South Wales. Commercial production began in 1924–25 and, favoured by tariff protection and high average yields, expanded sufficiently to meet Australia's domestic requirements by the early 1930s. Further expansion occurred during and after World War II. By the early 1960s there were 55,000 ac. devoted to this crop, which produced 7,000,000 bu., of which 36% was exported, mainly to Papua and New Guinea, the Pacific islands and the United Kingdom. Rice is grown on irrigated pastures; it is a highly mechanized industry, with high yields by world standards. Rice acreage (averaging about 57 per holding) is controlled by the quantity of water made available to each grower. Attempts are being made to develop commercial rice production at Humpty Doo, Northern Territory, and in Western Australia.

Green Fodder and Hay.—The area devoted to green fodder crops includes more than 4,800,000 ac. (1,900,000 ha.) made up of oats, alfalfa, wheat, barley, sorghum, rye and others. The sowing of green fodder crops to supplement natural grazing is a growing practice in the dairying industry. The area cut for hay fluctuates according to climatic and economic conditions but averages about 2,500,000 ac. Wheat and oats are the main crops used for cereal hay although the acreage has dropped as mechanization has increased.

Industrial Crops.—The area planted to industrial crops, consisting of sugarcane, flax, peanuts, tobacco and cotton, averages more than 700,000 ac.

Sugarcane production is confined to the coastal fringe of Queensland and northern New South Wales (particularly the Richmond river district). As this area has high summer rainfall (at least 40 in. annually) and no frosts, it meets the climatic requirements of this crop. More than half the sugar acreage is north of Mackay, Queensland, and one-fifth of the acreage is irrigated. The average area cut for crushing (360,000 ac.) is about 76% of the total, the remainder being young and standover cane or required for plants. The industry is controlled by joint commonwealth and Queensland government legislation, production being limited to demand by restricting the area under cultivation. Sugarcane cultivation is mechanized, but only 3% is mechanically harvested. About 92% of the raw sugar in Australia is now handled in bulk without being bagged at any stage.

Production of raw sugar in the early 1960s totaled approximately 1,830,000 tons, of which 61% was exported (some in the form of manufactured products). The industry is protected by an embargo on imports of sugar and a two-price system under which the local price is adjusted to ensure a reasonable, equalized return to the producer.

Flax is grown for flax fibre and linseed oil. The acreage of flax for fibre averaged about 6,000 ac., but in 1961–62 it fell to 400 ac. as the commonwealth government, which had taken an active interest in this industry, decided to withdraw. Production of flax for linseed oil began in 1948–49 during a world shortage; about one-fifth of Australia's needs are now met from 95,000 ac., mainly on the Darling downs, Queensland. This crop competes with wheat in the better wheat-producing areas.

Peanut growing is mainly confined to the Kingaroy district in southern Queensland. Average production is about 14,000 tons from 35,000 ac.

Tobacco is grown chiefly at Mareeba-Dimbulah, Queensland;

at Texas (on Queensland-New South Wales border); near Myrtleford, Victoria; and at Manjimup, Western Australia. Total acreage under tobacco was about 27,000, and production totaled 20,000,000 lb. of dried leaf (about one-third of Australia's requirements).

Cotton growing used to be confined to Queensland, but is it now also being grown in New South Wales and, experimentally, in the Ord river area of Western Australia, in South Australia and Victoria. The commonwealth government pays a bounty to growers based on quality and related to 16.125*d.* per pound for middling one-inch white raw cotton.

Orchards and Fruit Crops.—The varieties of fruit grown in various parts of the continent range from pineapples, pawpaws and mangoes in the tropics to strawberries, raspberries and currants in the cooler parts of the temperate zone. The acreage under orchards and fruit gardens averaged 290,000 in the early 1960s.

Vineyards.—The acreage under vineyards in the early 1960s was about 130,000 (53,000 ha.), concentrated in the Murray valley areas of South Australia, Victoria and New South Wales, where the crop was grown under irrigation. About 49% of the acreage produces grapes for drying, and the production of raisins and sultanas totaled 88,000 tons (of which 66% was exported) and of currants 8,000 tons (of which 59% was exported). Wine grapes are produced in the Barossa valley, South Australia, and at other vineyards along the Murray and Hunter rivers, in the Murrumbidgee irrigation area and in the Swan river valley, Western Australia.

Vegetables for Human Consumption.—Of the 270,000 ac. (110,000 ha.) devoted to producing vegetables for human consumption, about 35% is used for potatoes, two-thirds of which are grown in Victoria, New South Wales and Tasmania. A substantial amount of the fresh vegetables is grown near the main urban markets, but distant specialist growing areas became increasingly important by the 1960s.

Agricultural Organization and Policy.—Agriculture and marketing of products within a state are functions of the state government, but the commonwealth government has powers over interstate and overseas marketing of rural produce. (Commonwealth and state powers are both limited by sec. 92 of the constitution, under which interstate trade must be absolutely free.) Each state has an agricultural research and extension service, although the intensity of extension activities is limited by the great distances to be covered. State research work is supplemented by investigations carried out by the Commonwealth Scientific and Industrial Research organization.

State marketing boards have been established for a variety of products; the most important exception is wool, which is sold at auction to buyers from all over the world. Exports of agricultural products are in most cases governed by a series of export control boards (wheat board, Australian meat board, Australian dairy produce board, etc.), on which producers have a majority representation. During and after World War II many rural exports (but not wool or wheat) were sold under intergovernmental contract on a bulk basis to the United Kingdom. Generally, policy has favoured stability in internal and overseas marketing of primary products because of the importance of agriculture and the inflationary effects of fluctuations in export income. Hence, Australia was a party to the International Wheat agreement and the Commonwealth Sugar agreement and introduced stabilization schemes for the wheat and dairy industries.

Internally, co-ordination of agricultural policy at the commonwealth level is achieved through the Australian Agricultural council (consisting of commonwealth ministers for primary industry and the territory and state ministers for agriculture) and its subsidiary, the standing committee on agriculture, on which administrative and technical officers of state and commonwealth are represented.

After World War II Australia suffered from a major drought (1944–46) and from grave shortages of materials, equipment and manpower. Thus, despite a stronger financial position than existed before the war, the rate of increase in farm productivity not only lagged behind need but also behind achievements in the United Kingdom and the U.S. A five-year agricultural expansion program began in 1952, which substantially assisted the industry; production in the early 1960s was 35%–40% above prewar, and 50% above immediate postwar, years.

Australia's agricultural problem at the beginning of the 1960s was not productivity but the steady deterioration in world commodity prices and hence declining export values, and the competition represented by high domestic subsidies in continental Europe and in the United Kingdom and the dumping of U.S. surpluses. Policies set forth in the General Agreement on Tariffs and Trade (G.A.T.T.) and elsewhere are concerned with minimizing restrictions on Australia's exports.

Forestry.—Most of the original forest cover was cleared to make way for crops, pastures and settlements, and to supply the timber needs of an expanding economy. It was estimated in the early 1960s that the total area of forest in Australia was 512,000,000 ac. (207,000,000 ha.), or about one-quarter of the total land area of the continent, but only 19,200,000 ac. consisted of residual prime native forest. Four-fifths of the total forested area carried only sparse, stunted tree growth. Of the accessible forest area (320,000,000 ac.), only 30,000,000 ac. were in productive use. Forests fit for commercial exploitation are mainly restricted to the wetter belts of the coastal areas and near-coastal highlands of the eastern states and to the extreme southwest of Western Australia.

About 94% of the indigenous forest area consists of hardwoods. The genus *Eucalyptus* (of which there are more than 500 species, most of them indigenous to Australia) grows under a wide range of climatic conditions, ranging from the cold, wet uplands of Tasmania to the hot, dry inland areas of Western Australia. The genus includes such species as the mountain ash (*E. regnans*) of Victoria and the karri (*E. diversicolor*) of Western Australia. In the drier areas, by contrast, there are thickets of small, multiple-stemmed eucalyptus trees collectively known as mallees.

Less than 100 eucalypts are used for sawmilling, and only about 40 are exploited intensively. Among the outstanding commercial species are jarrah (*E. marginata*), mountain ash, blackbutt *E. pilularis*), spotted gum (*E. maculata*), messmate (*E. obliqua* karri, alpine ash (*E. gigantea*), tallowwood (*E. microcorys*), Murray red gum (*E. camaldulensis*) and ironbark (*E. paniculata* and others).

Commercial hardwoods of other genera include numerous furniture, cabinet and veneer timber trees, well known among which are red cedar (*Cedrela toona*, variety *australis*), Queensland maple (*Flindersia brayleyana*), southern and northern silk oak (*Grevillea robusta* and *Cardwellia sublimis*), Queensland walnut (*Endiandra palmerstonii*), blackwood (*Acacia melanoxylon*) and rosewood (*Dysoxylum fraserianum*). Turpentine (*Syncarpia laurifolia*) ranks with the world's best for wharf piles.

The most important indigenous softwoods were the forests of hoop pine (*Araucaria cunninghamii*) of Queensland and New South Wales. Although the greater part of the original hoop pine forest has made way for intensive agriculture, some areas in Queensland and, to a lesser extent, in New South Wales have been replanted with this species. Other native softwoods that have played a useful but minor part in the Australian timber industry include the bunya pine (*Araucaria bidwillii*) and the kauri (*Agathis* species) of Queensland, and the Huon pine (*Dacrydium franklinii*), celery-topped pine (*Phyllocladus rhomboidalis*) and King William pine (*Athrotaxis selaginoides*) of Tasmania.

To help overcome the deficiency in softwoods, 580,000 ac. of softwood plantations (75% of this area government owned) have been established. The principal species is *Pinus radiata*, but in subtropical regions *P. caribaea* and *P. taeda* have proved more successful. There are 31,000 ac. of hardwood plantations (mainly *Eucalyptus* species), but of greater importance are the areas of controlled natural regeneration of native hardwoods.

Sawn timber production exceeds 1,350,000,000 super. ft. annually. Much of this total is hardwood. Other timber, *e.g.*, sleepers (railroad ties), piles, fencing material, timber for mining, fuel is also cut, and an increasing quantity of pulpwood is being made for paper and fibreboard manufacture.

Australia has always been an importer of timber, largely to

make up for its lack of softwoods. Exports consist mostly of hardwoods (logs and undressed timbers).

Mining.—Mineral deposits in Australia occur in a region of Pre-Cambrian rocks in the western and central part of the continent—the relatively stable shield area—and in the region of folded Paleozoic rocks of the Tasman geosyncline in the east.

Exposed Pre-Cambrian rocks include much of Western Australia, South Australia and the Northern Territory, as well as portions of western Queensland and western New South Wales. They contain deposits of lead-silver-zinc, gold, tin, tantalum, mica, beryllium, manganese, uranium, etc.

Paleozoic rocks fringe eastern Australia from northern Queensland southward to include much of Tasmania and are host rocks for deposits of gold, copper, lead-silver-zinc, tin, tungsten, molybdenum, bismuth, etc. The highest-quality coal is found in Permian strata (the youngest Paleozoic rocks) in New South Wales, Queensland and, to a lesser extent, in Tasmania and Western Australia. Triassic (the oldest Mesozoic) rocks contain the most important deposits of coal in Queensland, Tasmania and South Australia, and Tertiary deposits of lignite (brown coal) occur in Victoria.

The almost unfolded rocks of the great Jurassic-Cretaceous-Tertiary basin from the Gulf of Carpentaria to the lower Murray valley lack metallic ores. While it may be expected that the great mass of the Pre-Cambrian shield is as rich as its margins, vast areas are covered by thick desert sands. However, the sedimentary rocks were deeply weathered during the Tertiary period, and opals and bauxite were formed near the surface.

The development of the Australian mineral industry began with the discovery of copper in South Australia in 1842. It was followed by the discovery of gold in the eastern states in 1851; of copper, tin and lead-zinc in the eastern states and Tasmania (Mt. Bischoff, 1871; Broken Hill lode, 1883; Mt. Lyell, 1886); and of rich goldfields in Western Australia (Coolgardie, 1892; Kalgoorlie, 1893). Apart from their monetary value an important effect of these discoveries was the encouragement given to settlement inland.

Australia is deficient in a few vital minerals, including petroleum, rock phosphate, elemental sulfur and tin. New deposits of bauxite, iron ore, manganese, copper and uranium have been discovered, and new developments have occurred in some of the older mining areas, such as Broken Hill; Mount Isa, Queensland; and Mt. Lyell, Tasmania.

Of the total local value of Australian mineral output in 1961, metallic minerals made up 42% (copper ore 12%, lead and lead-silver ore 9%, gold ore 9%, iron ore 3% and zinc concentrate 3%); fuel mining made up 36%; and nonmetallic mineral mining 22%.

Each state administers its own mining industry, determines the

GODFREY LINGE WITH ACKNOWLEDGEMENTS TO THE "ATLAS OF AUSTRALIAN RESOURCES"

FIG. 8.—MAJOR MINERAL RESOURCES IN AUSTRALIA

level of royalties, provides financial assistance and operates a geological department. The commonwealth government administers mining in the territories, controls the export of certain metals and minerals, operates the bureau of mineral resources, geology and geophysics and provides financial assistance.

Coal.—All the good-quality coal in Australia is Permian or later. Of the measured and indicated reserves of semianthracite (small amount only) and bituminous coal, 90% is in New South Wales; of subbituminous reserves 65% is in New South Wales, and smaller amounts are in Western Australia and in South Australia; practically all the brown coal reserves are in Victoria. Inferred reserves of all grades of coal are large except in South Australia.

Black coal production in Australia exceeded 24,850,000 tons in 1963, 90% being obtained by underground working. The exploited seams are rarely deeper than 1,500 ft., and, although they vary in thickness, the gradients are flat and few problems arise from water or gases. At Callide and Blair Athol, Queensland, the seams, being 50 ft. or more thick, are among the thickest suitable for opencut working in the southern hemisphere.

Most Australian black coal is obtained in New South Wales and comes almost entirely from Permian deposits in a basin extending along the coast from Newcastle to Ulladulla and inland to Dubbo and Gunnedah. The chief workings are in the Hunter valley, in the vicinity of Newcastle, Maitland, Cessnock and Muswellbrook, with others around Lithgow and Bulli-Wollongong. Most large coalfields are located in the coastal region in areas with good rainfall, ample water supply and well-developed transport systems, and, being near large urban centres, are conveniently placed to supply secondary industry.

Australia exported 3,175,000 tons in 1963, mainly to Japan. In the 1960s overseas interests exploited coal deposits, particularly those that could be worked by opencut methods in Queensland, for export. For instance, from Moura, coal is exported to Japan through Gladstone, 200 mi. (320 km.) E.

The chief deposit of brown coal in Australia is a faulted-down trough of Tertiary brown coal around Morwell, 80 mi. E. of Melbourne. This fuel is used for electricity generation (at Yallourn), for briquetting and for the production of town gas (at Morwell), which is piped to Melbourne.

Iron.—Iron ore is widely distributed throughout Australia. In recent years very large reserves have been discovered—those in Western Australia alone have been conservatively estimated at more than 8,000,000,000 tons. In 1938 the commonwealth government prohibited the export of iron ore but early in the 1960s relaxed this embargo and by the end of 1964 had given approval for the export of 500,000,000 tons (mainly from Western Australia) over a period of years. Output in the early 1960s came from the Iron Monarch and Iron Baron deposits (Middleback range, South Australia) and from Yampi sound (Western Australia). Although some ore is smelted at Whyalla, South Australia (30 mi. [48 km.] from Iron Baron), and ore from Koolyanobbing is smelted at Wundowie, Western Australia, all that from Yampi sound is shipped to Newcastle and Port Kembla on the coalfields of New South Wales.

Lead, Zinc and Silver.—Australia is also a major producer of lead, zinc and silver. Much of the output of these metals comes from Broken Hill; other sources include Mount Isa, and Read-Rosebery, Tasmania.

Ore is dressed to concentrates at the mines. The Broken Hill lead and silver are converted into metal at Port Pirie or exported as concentrates, and the Mount Isa lead is smelted at the mine and exported as bullion. About half the Broken Hill zinc concentrate is exported overseas from Port Pirie, and the remainder is electrolytically treated (together with the whole of the output from Rosebery) at Risdon, near Hobart, Tasmania. Mount Isa zinc concentrates are all exported. About 92% of the silver is a by-product of lead-zinc mining.

Tin.—The annual mine production of tin averaged about 2,700 tons, produced mainly in Queensland and Tasmania, with small quantities coming from the other states. Imports of refined tin exceeded 1,775 tons.

Copper.—The mine copper production increased considerably after World War II and by the mid-1960s averaged about 120,000 tons. Half the Australian total comes from the Mount Isa mine and lesser amounts from Mt. Lyell; Mount Morgan, Queensland; and the Peko mine at Tennant Creek, Northern Territory. Blister copper is produced at Mount Isa, Mount Morgan, Port Kembla and Mt. Lyell, and refined at Townsville, Port Kembla and Mt. Lyell.

Gold.—Gold produced since 1851 amounts to more than 181,000,000 fine ounces (gold content of minerals produced), most of which comes from Western Australia and Queensland. With an annual average production of 1,100,000 fine ounces, Australia ranks fifth in world output. Of the Australian output, Western Australia produces 81%, more than one-half from the Coolgardie fields and much of the remainder from the Murchison, Dundas and Yilgarn fields. Other producing areas are Broken Hill; Chewton, Victoria; Mount Morgan and Cracow, Queensland; Tennant Creek; and Rosebery.

Original diggings were in superficial alluvial deposits that contained several nuggets of more than 1,000 oz., including the "Welcome Stranger," which weighed 2,520 oz. The exhaustion of easily worked deposits and increased costs of deep mining caused gold production in Australia to decline after 1903.

Uranium.—Production of uranium oxide is now confined to treatment at the Rum Jungle (Northern Territory) plant of stockpiled ore, and at the current rate it would operate until 1971. Production of uranium oxide totaled 1,084 tons in 1963, but the Mary Kathleen plant ceased operations at the end of that year.

Oil.—Australia is deficient in oil; crude oil and petroleum products form the largest single import item. The 70-year search for oil was rewarded in 1961 when a field was discovered at Moonie, 190 mi. (306 km.) W. of Brisbane (Queensland). Since then new strikes or developments have been frequently announced. In March 1964 the Moonie field came into commercial operation, and crude oil was pumped along a new 200-mi., 10-in. pipeline (built at a cost of £A5,000,000) to Brisbane. More recently oil has been found at Alton, 55 mi. S.W. of Moonie, and the pipeline was to be extended there.

Natural gas prospects are also good. Since 1961 natural gas from Roma (280 mi. W.N.W. of Brisbane) has been used for electricity generation, and there are proposals for a pipeline to Brisbane. Four potentially important discoveries of natural gas have been made 280 mi. W. of Roma, 500 mi. N. of Adelaide, 120 mi. S.W. of Alice Springs and on Barrow Island, 900 mi. N. of Perth.

Total expenditure to 1962 on oil exploration in Australia and its territories exceeded £A100,100,000, 14% of which was contributed by government sources. During the years 1956–60 alone £A20,775,000 of overseas capital was invested in oil exploration, of which 60% was spent in Papua and New Guinea, 32% in Western Australia and 5% in Northern Territory. The commonwealth government encouraged the search for oil by tax concessions, subsidies and geological and geophysical investigations.

Bauxite.—Large deposits of bauxite at Weipa (north Queensland) and Darling range (Western Australia) were being developed in the 1960s. Weipa output grew from less than 20,000 tons in 1962 to 310,000 tons in 1963, of which two-thirds was exported to Japan and one-third smelted at Bell bay (Tasmania). A 200,000-ton capacity smelter was built at Kwinana (Western Australia), and one of 600,000-ton capacity was being built at Gladstone (Queensland) to begin operations in 1967.

Other Minerals.—Australia is the world's leading producer of rutile and zircon. Rutile (an oxide of titanium) is the main raw material for titanium metal and the principal mineral recovered from the eastern coast beach sands. Australian titanium production, stimulated by growing world demand, increased greatly. Opals are obtained mainly from the Coober Pedy and Andamooka fields, South Australia, and Lightning Ridge, New South Wales.

Adequate supplies are available of nearly all the raw materials required for the production of plaster, glass, earthenware, bricks, 'les and cement. Materials required in metal smelting, such as mite, fluorspar, magnesite and limestone, are also produced in Australia, and salt is obtained by evaporation of seawater and from inland salt lakes.

Fisheries.—Fish stocks in the southern hemisphere are small by comparison with those in the northern hemisphere, where most of the world's fish are obtained. The Australian catch is small, and sea food has to be imported.

Estuarine fishing takes place around the coast from Cairns, Queensland, to Ceduna, South Australia, and from Geraldton to Esperance, Western Australia. Mullet, Australian salmon and tuna make up about 40% of the Australian fish catch. Demersal fishing grounds consist of the reefs from which cod, snapper, etc., are taken, extending from northern Queensland around the southern part of the continent to Western Australia, and the continental shelf, from which flathead, morwong, etc., are taken off southeastern Australia and off the eastern Tasmanian coast. Demersal school shark grounds lie principally in Bass strait and off eastern South Australia. Snapper, flathead, morwong and shark make up 25% of the catch.

Pelagic or deep-sea fishing grounds include that for Spanish mackerel off the northeastern coast; that for barracuda in Bass strait and off eastern Tasmania; that for jack mackerel off southeastern New South Wales, eastern Tasmania and Western Australia; and that for tuna off New South Wales and Tasmania. Pilchards (sardines) are found from Moreton bay, Queensland around the southern coast of Australia to Western Australia, and anchovies are caught in Port Phillip bay and in Lakes Entrance, Victoria. Australian fisheries developed from onshore fishing to demersal reef fishing with long lines and, during World War I to trawling off the New South Wales coast; most vessels are Danish seiners. Tuna fishing increased considerably after the commonwealth government demonstrated in 1950 that this species could be caught in commercial quantities.

The annual average production of crustaceans totaled 39,000,000 lb. gross weight in 1961–62, of which crayfish represented 74% and prawns 20%. Crayfish production increased after 1945 to take advantage of the U.S. market for crayfish (lobster) tails.

Australia is the world's chief producer of pearl shell. Pearling is centred on Thursday Island, Torres strait, and at Broome, Western Australia and Darwin, Northern Territory. In 1956 a company began culturing pearls in Brecknock harbour, 270 mi. N of Broome.

In the early 1960s five coastal whaling stations operated, but by 1965 there was only one, at Cheyne Beach, Western Australia. The others had closed because of the shortage of whales.

Manufacturing.—Apart from the growing local market, events that fostered the growth of factory industry include: federation in 1901, with centralized customs and tariff control, a single tariff policy toward other countries and internal free trade; the extension of protection during the 1930s; and the stimulus of World Wars I and II. Spectacular growth took place during and after World War II. employment in manufacturing increased, and large amounts of capital were invested in both new and existing industries, including oil refining and the manufacture of motor vehicles, steel, chemicals and plastics. Although the United Kingdom has traditionally been the largest investor in Australian industry the United States provided about 30% during 1953–60. Net immigration from overseas (averaging about 90,000 persons a year since 1946) has greatly assisted in providing manpower for expansion and in stimulating local demand for manufactured products in the iron and steel industry, for example, about 25% of labour is supplied by immigrants.

The net value of production of Australian factories was about 60% of the total net value of recorded production. The chief groups were industrial metals, machines and conveyances; food drink and tobacco; clothing and textiles; chemicals, dyes and explosives; and paper, stationery and printing.

Manufacturing is concentrated in the state capitals, which have 73% of all factory workers as compared with 56% of the population. Each of the mainland capitals has attracted a dominant share of the state's industrial activities because of the availability of markets, labour, fuel, business and government contacts, and access to overseas and internal transport systems. Much of the

remaining industrial activity is located at a few large provincial centres on or near the coast, *e.g.*, Newcastle, Wollongong-Port Kembla, Geelong and Launceston, and at some inland urban areas; *e.g.*, Ballaarat and Bendigo. The leading industrial state is New South Wales followed by Victoria. The state governments compete with one another for industrial development and conduct separate promotion programs at home and overseas.

Industrial self-sufficiency has been pursued in Australia since the beginning of World War II, but the local market was not large enough to warrant the manufacture of some specialized machinery and apparatus. The metallurgical industry, by far the most important, does provide a measure of self-sufficiency in the basic requirements of manufacturing.

Basic Metal Industries.—The main centres of iron and steel production are the coastal cities of Newcastle, Wollongong-Port Kembla and Whyalla. There are completely integrated steelworks at Newcastle and Port Kembla, with a combined ingot steelmaking capacity in the early 1960s of 4,400,000 tons. These works draw ore from the Middleback range (South Australia) and from Yampi sound on the northwest coast. Limestone is obtained from Rapid bay, 60 mi. (97 km.) S. of Adelaide, and from Marulan, 75 mi. N.W. of Port Kembla. In May 1965 work was completed on a second blast furnace and other facilities that transformed Whyalla into Australia's third integrated iron and steel centre; it used coking coal from New South Wales and ore from the Middleback range. The rolling mill at Kwinana was being extended, and plans were in hand for a blast furnace and, later, for other facilities to make this the fourth steelworks in Australia; it would use iron ore from Koolyanobbing (360 mi. N.E. of Perth).

The Broken Hill Proprietary Company Ltd. (B.H.P.), by far the largest nongovernment enterprise in Australia, dominated the iron and steel industry both directly and through its subsidiaries and associates. In the mid-1960s this organization owned all the Australian blast furnaces and steelmaking capacity, except for a few electric and charcoal furnaces. Also within this combine are factories making pipes, wire and stainless steel products. In addition, B.H.P. operates the largest privately owned fleet in Australia, to carry ore, coking coal and finished products. Firms outside the group operate rolling mills and galvanizing works at Newcastle and Port Kembla, using feed from the steelworks, and have fabrication factories in most states.

Transport Equipment and Engineering.—World War II stimulated the Australian shipbuilding and repairing industry. There are five major shipyards, located at Sydney, Newcastle, Whyalla, Melbourne and Brisbane, and from 1942 to 1960, 75 merchant vessels, as well as naval and other craft, were launched.

Eight firms, all associated with overseas organizations, with a combined capacity of 330,000 units a year, assemble or manufacture locally about 95% of the passenger motor vehicles sold in Australia. In 1964 the commonwealth government compelled car manufacturers to increase the Australian component in their total costs to 95% within five years or suffer heavy tariff penalties. This stimulated still further investment in the industry. Exports total about 10,000 units annually. About 25,000 persons are engaged in the manufacture of vehicles, and 100,000 in their repair.

Australia produces much of its requirements of electric motors, as well as transformers, cables, electrical control gear, and radio and television equipment. Other products include railway equipment, machine tools, metal-working machinery, agricultural machinery, gasoline engines, pumps, builders' hardware and domestic appliances.

Oil Refining.—The eight main refineries in Australia are located on the coast at Kurnell (two), Matraville and Clyde (New South Wales); Geelong and Altona (Victoria); Kwinana; and Halletts Cove (South Australia). Only one of these was in operation before 1948. Two refineries under construction at Brisbane would receive part of their crude oil by pipe from the Moonie and Alton fields. Capacity increased from 800,000 tons in 1954 to 21,330,000 tons in 1965. A new oil refinery was being constructed near Melbourne.

Textiles.—The Australian wool textile industry consumes about 7% of the wool clip. There are about 135 woolen mills (mainly in Victoria and New South Wales) producing woolen and worsted cloth, blankets and rugs. Many mills are vertically integrated, undertaking all or most of the processes from wool scouring to weaving and finishing. Cotton-spinning and weaving mills use mainly imported raw cotton to produce an extensive range of goods, including duck and canvas, denims, drill, etc., and tire cord and fabric. Since 1961 three firms have started fine count spinning.

Power.—The total installed electric generating capacity was 7,220,000 kw.hr. in 1962. Steam plants generated power mainly from coal, of which nearly one-half was from the lignite deposits in southeastern Victoria. In addition small but increasing amounts of fuel oil were used. Improvements in high-voltage transmission and rising transport costs inspired the building of coal-fired steam plants near the coalfields, away from the main load centres.

Hydroelectric power plants are restricted to the elevated regions that receive adequate and reliable rainfall, such as the highlands of Tasmania and southeastern mainland Australia, as well as some minor schemes in Queensland. Most hydroelectric power projects have been built primarily for electricity generation, *e.g.*, the Tasmanian system and the Kiewa scheme in Victoria, or as ancillary to water storage for irrigation purposes; *e.g.*, Burrinjuck dam in New South Wales and Eildon dam in Victoria.

The Snowy Mountains hydroelectric scheme is a 30-year project being designed and constructed by the Snowy Mountains authority (a commonwealth instrumentality constituted in 1949), which will supply both electricity and irrigation water by diverting the waters of the Snowy river system to the inland, westward-flowing Murray and Murrumbidgee systems. The scheme is due to be completed in 1972 and is expected to cost about £A400,000,000.

In Tasmania hydroelectric power stations produce both the base and the peak load power, whereas in general the mainland stations are used to supplement the thermally produced base load at times of peak demand. (G. J. R. L.)

B. Trade and Finance

Foreign Trade.—Australia has always depended on foreign trade. During the 19th century the Australian colonies developed as suppliers of primary products to the British market and relied on British industry for most manufactured items. Domestic industrial development has not significantly diminished the importance of foreign trade to the Australian economy, although there have been great changes in the types of goods imported, and by mid-20th century there were the beginnings of an export trade in domestic manufactures. The average annual exports in the mid-1960s accounted for about 20% of the gross national product.

As an exporter of primary products whose prices have tended to fluctuate greatly in world markets and as a borrowing country dependent on fluctuating supplies of overseas capital, Australia has always been exposed to balance of payments difficulties. Between 1940 and 1960 it relied heavily on quantitative import controls to cushion the domestic economy against these disturbances, in addition to substantial international reserves.

Since the 1880s Australia has fostered domestic industrial development by protective tariffs, administered after the 1920s by a tariff board, which hears applications by industries seeking protection and makes recommendations to the government. In 1932 Australia subscribed to the Ottawa agreements, under which it granted preferential tariff treatment to British manufactures in exchange for preferences granted to its own exports in the British market under United Kingdom tariff and quota restrictions. After World War II the importance of these preferences diminished.

Imports.—Until the early 1950s industrialization had little effect on Australia's dependence on imports, measured by the ratio of imports to gross national product. But there has been a striking change in the types of goods imported. The share of finished consumer goods fell from 28% in 1913 to less than 17% in the 1960s; that of capital equipment rose from 17% to about 30%; that of producers' materials remained stable around 45%, but within this category there was a sharp shift from elaborately transformed to crude materials. There was some evidence of effective import replacement, real gross national product rising by 20% without any increase in imports. 1860s

The United Kingdom remained Australia's largest supplier. In the mid-1960s the United States and Japan came next, followed by the Federal Republic of Germany, Canada and the Arabian states (oil). Sterling area countries supplied two-fifths of the total.

Exports.—Primary products (including minerals) accounted for about 85% of the exports, and manufactures (including processed foodstuffs) for the remainder. Chief export items were wool, meat, wheat, dairy products, sugar, fruit and minerals (chiefly lead and zinc). By the mid-1960s the U.K. barely retained its lead as Australia's major market, taking only 19% of Australia's exports, just half of the total sterling area share. Both Japan and the European Economic community approached the British level, followed by the U.S. and the People's Republic of China.

Other Overseas Payments and Receipts.—Even in years of balanced merchandise trade, Australia had a regular deficit in its balance of payments on current account usually amounting to about £A200,000,000. This resulted from interest and profit due overseas on capital invested in Australia and from other invisible imports, especially freight, insurance, travel and immigrant remittances. Much of this deficit was offset by a substantial inflow of overseas capital. Whereas in the 19th century overseas investment in Australia mainly took the form of borrowing in London by Australian governments, the large inflow after World War II consisted mainly of direct investment and reinvestment by overseas (chiefly British and U.S.) companies in Australian industries. The only substantial net overseas borrowing on government account was from the International Bank for Reconstruction and Development.

Finance.—Since federation, the Australian system of public finance has undergone a drastic shift of financial power and responsibility from the states to the commonwealth. The main stages in this process, which accompanied the growth of governmental responsibility for economic policy and of the public sector in the economy, were: the commonwealth-state financial agreement (1928), under which the commonwealth assumed responsibility for state public debts and for all borrowing by the government; the introduction of uniform taxation (1942), under which the commonwealth assumed a monopoly of income taxation, coupled with reimbursement grants to the states; and the assumption of *de facto* control by the commonwealth over the total amounts available to the states for current and capital expenditure. The state governments remained responsible, under the constitution, for most functions of government involving expenditure (other than national debt interest, defense and social services), but their current expenditure was financed chiefly by commonwealth grants and to a lesser degree by their own tax revenue, while the larger share of their capital expenditure was financed by commonwealth taxation.

Total (commonwealth and state) taxation absorbed about 23% of the national income. Tax revenue of the commonwealth was derived mainly from personal income tax, company tax and indirect taxes (chiefly customs and excise, sales tax and payroll tax). State and local authorities relied for their tax revenue mainly on miscellaneous indirect taxes (rates and land taxes, stamp duties, etc.) and succession (inheritance) duties. The main items of public authority expenditure include cash social service benefits, national debt interest, public works, defense, education and health.

Australia's system of private finance was, until the 1950s, dominated by the large trading banks; there are seven private banks (two with head offices in London) and the government-owned Commonwealth Trading Bank of Australia. There are also some small state banks, the Reserve Bank of Australia (until 1959 called the Commonwealth Bank of Australia) and several savings banks. After the establishment in 1912 of the Commonwealth Bank of [illegible]stralia as a central bank with trading functions, banking [illegible] bject of political controversy. The Labor govern[illegible] ion in 1947 to nationalize the private banks was [illegible] tional by the courts. The reorganization of the [illegible] 1959 grouped the trading, development and sav[illegible] ies of the central bank into a separate Common[illegible] poration.

By the early 1960s the domestic Australian capital market had developed greatly. The main features were the rapid growth of hire-purchase (installment) finance, the new issue market (especially for fixed interest finance by companies), development banking and the establishment (1959) of an official short-term money market. The older financial institutions, the trading banks and life assurance companies reacted to this competition by themselves branching out into the new fields of finance.

In 1964 Australia announced the monetary system would be converted from the British system of pounds, shillings and pence to the decimal system of dollars and cents, effective in 1966.

(H. W. A.; A. J. Ro.)

C. Transport and Communications

Australia covers a large area, with a low density of population in its arid interior and a concentration of settlement in a comparatively narrow coastal belt. Long distances separate the main centres of population and industry. These factors explain the peripheral arrangement of the various transport systems that radiate from the state capitals. Much of the railway mileage, for example, lies within 200 mi. of the coast, with occasional lines penetrating inland to tap pastoral or mineral resources.

Until about the end of the 1930s roads and railways were essentially complementary, but since then they have become highly competitive as road haulage has proved more economical and flexible for nonbulky and specialized types of freight. State governments, having considerable sums of money invested in their state railway systems and being compelled for political or community reasons to keep many unprofitable lines open, attempt to control road and rail competition. New South Wales, for instance, makes a levy per ton-mile on intrastate (but not, by constitutional bar, on interstate) road journeys. Queensland forbids road haulers to charge less than the railway rate for a given journey. Even so, and despite road maintenance taxes imposed by state governments on freight-carrying road vehicles on both interstate and intrastate journeys, road transport can still compete effectively with railways. By offering freight concessions, state railway systems compete for the border trade of neighbouring systems, but occasionally they have taken joint action to prevent trade from falling into the hands of road haulers: thus concessions are offered by the New South Wales railways on wool dispatched from Riverina through Tocumwal, despite the fact that it then goes to Melbourne or Geelong on the Victorian system.

Roads.—There are about 61,000 mi. (98,000 km.) of proclaimed or declared main roads out of a total of 564,000 mi. (908,000 km.) of road, that are open for general traffic. World War II stimulated the construction of an all-weather bitumen road between Alice Springs and Darwin—the 950-mi. Stuart highway—and the reconditioning of others, such as that across the Nullarbor plain between Port Pirie and Norseman. After World War II road authorities faced great problems: maintenance had been neglected, and there was a greater volume of traffic traveling at faster speeds and carrying heavier loads.

Despite existing shortcomings, a tremendous effort has been put into road improvement since 1945. Motor transport is playing an increasing part in the development of the pastoral industry both in the movement of wool and stock and in the carriage of fodder during droughts. "Road trains," which consist of a diesel-engined prime mover and two or three trailers that can carry about 800 shorn sheep or 80 cattle at about 15–20 m.p.h., are used in remote parts of Australia. The commonwealth and state governments are financing a "beef roads" complex in northern areas designed to allow stock to be moved quickly in all seasons to the fattening country. The use of heavy road vehicles for long-distance haulage between capital cities has been a feature of postwar years.

Railways.—The railway systems, originating independently, were each centred on a state capital and used different gauges. Victoria adopted the broad gauge (5 ft. 3 in.), New South Wales the standard (4 ft. 8½ in.), Queensland, Western Australia and Tasmania the narrow (3 ft. 6 in.). South Australia built some lines linking with the Victorian broad-gauge system, and others on narrow gauge. The costs and delays at the breaks of gauge a

GODFREY LINGE

FIG. 9.—RAILWAYS IN AUSTRALIA

the state borders and elsewhere greatly affected Australian development. In 1930 the standard-gauge line from Sydney to Kyogle was extended to Brisbane, and in 1962 a standard-gauge line from Melbourne to Wodonga joined Sydney and Melbourne. Melbourne is linked to Adelaide by a broad-gauge line. A 380-mi. standard-gauge line from Kalgoorlie to Kwinana and Fremantle was due to be finished in 1967 at a cost of £A41,000,000.

The state systems are under the control of their respective governments, and, with the exception of Tasmania and Queensland, each radiates outward from the state capital—usually the chief port. Victoria has the densest railway network with 4,290 route miles. The Townsville to Mount Isa line has been modernized.

The commonwealth owns a short line linking the Australian Capital Territory with the New South Wales system, and three major lines, namely the Trans-Australian railway (standard) linking Kalgoorlie and Port Augusta with Port Pirie, the Central Australia railway (mostly narrow) linking Port Augusta with Alice Springs, and the North Australia railway (narrow) linking Darwin and Birdum.

Freight rates are calculated within each state on a tapering principle—a lower rate per ton-mile for longer hauls. Even though the states have reached some measure of agreement about goods traveling interstate, the rates charged are still higher than if the tapering principle were fully operative on such journeys. This is one of the main reasons why commodities tend to be sent to the capital of the state in which they are produced in spite of the fact that the capital of another state may be nearer. The processing of local products in country towns has been discouraged by the high rates charged on finished goods as against those on primary produce traveling to the seaboard. Freight handling at breaks of gauge is speeded by the use of bulk containers that are transferred bodily from one freight car to another, and some use is made of the "piggyback" system, whereby fully laden road trailers are transported on flat rail freight cars.

Some lines have been electrified, including that from Sydney to Lithgow, from Sydney to Gosford and from Dandenong to Gippsland. Several unprofitable lines have been closed, especially in Western Australia. The only underground railway is in Sydney.

Most of the several hundred miles of privately owned narrow-gauge railway serving mining, quarrying, forestry and sugar enterprises are not open for general use. However, part of the standard-gauge railway system around Newcastle is privately owned, although parts are operated by the New South Wales railways and some of it carries passengers.

Shipping.—Competition from commonwealth-owned shipping and from road and rail transport caused severe setbacks to private shipowners. Furthermore, lower productivity, partly brought about by the working conditions demanded by labour organizations, has slowed down the turn-round of vessels; in 1937, for instance, 2,500 tons of general cargo usually could be handled at the port of Melbourne in three and a half days whereas the time taken in 1956 was six and a half. The only prospering trade in post-war years has been the carrying of bulk cargoes, such as sugar, from Queensland to the southern ports, and iron ore from Yampi sound and Whyalla to the steel plants at Newcastle and Port Kembla. The Australian Coastal Shipping agreement (1956) has helped to minimize uneconomic competition.

Relatively long hauls along the coasts of Queensland and Western Australia allow the vessels engaged in intrastate trading to remain reasonably competitive for some types of cargo. However, coal shipped from Newcastle and Catherine Hill Bay to Sydney formed more than one-half the tonnage of intrastate cargo carried in 1957–58, and since then shipments of coal have decreased partly because of the increasing use of diesel locomotives, the construction of power stations at the coalfields and the substitution of by-product fuel oil from the Australian oil refineries. In the 1960s new passenger-vehicular vessels began operating between Tasmania and the mainland.

Ports.—About 100 commercial ports are situated along the coastline of Australia, together with many small seaports, jetties, landing stages and inland river ports at which trading vessels seldom call. Sydney, Melbourne, Fremantle (the port for Perth), Port Adelaide, Geelong, Port Kembla, Whyalla, Brisbane and Hobart handle (in that order) the greatest tonnages. Included are the ports of each of the capital cities, which contain a considerable proportion of the population of each state and much of their industrial and commercial activity. Some ports have highly specialized trades; for example Whyalla, Yampi sound, Rapid bay, Strahan and Catherine Hill bay, which are chiefly concerned with the handling of minerals.

Some ports, *e.g.*, Sydney, Hobart and Albany, are situated in natural deep harbours. Others lie behind artificial breakwaters, *e.g.*, Port Kembla, Burnie, Portland, Townsville and Mackay, or are located at river mouths, *e.g.*, Melbourne, Newcastle, Fremantle and Port Adelaide, or are a few miles upstream; *e.g.*, Brisbane, Launceston, Maryborough and Rockhampton.

Inland Waterways.—The river trade in Australia, particularly on the Murray and Darling rivers, reached its zenith in the 1860s

and 1870s. Being unable to compete against other forms of transport, it has now almost completely ceased. Some small craft operate on a few east coast rivers, such as the Hunter and Hawkesbury, but a revival of the river steamer and barge traffic on a large scale is unlikely.

Air Transport.—Regular air services operating throughout the continent link most major towns and many smaller centres. Frequent passenger and freight services operate between the capital cities. The volume of freight handled per head of population is greater than in any other country, and the passenger mileage per head is exceeded only by the U.S. Two airlines account for most of the passenger miles performed and the bulk of the ton-miles of freight carried within Australia. Six other companies operate regular services, some of which provide the only regular contact with many widely spaced cattle stations; and a number of firms undertake charter services or specialized work, such as spreading fertilizer and dusting crops.

The air ambulance and royal flying doctor services provide medical aid for the outback regions of Australia when called upon by a widespread system of local transmitters and radio bases. The commonwealth department of health operates the Northern Territory aerial medical service, and the royal flying doctor service, founded in 1928 by the Australian Inland mission, operates several bases in outback Northern Australia. The Bush Church Aid society for Australia and Tasmania (supported by Church of England funds) and the Federal Methodist Inland mission operate aircraft in the outback.

Overseas services go to the United Kingdom via North America, Mexico or the middle east, and to South Africa, Japan, New Zealand and other parts of the Pacific.

Postal Services and Telecommunications.—Letter sorting has been mechanized at the main offices, and distribution is carried out by road, rail, ship and air transport.

Communication facilities include a radiogram service to certain isolated places, a phototelegraph service for the reception and transmission of overseas photographic images and a teleprinter service. Transceivers bring remote stations and townships into the postmaster general's communication system. The Overseas Telecommunication commission operates overseas radio and cable services.

Current history and statistics are summarized annually in *Britannica Book of the Year*.

AUSTRALIAN ABORIGINES, the native race of Australia, have dark chocolate-brown skins. Their head hair, varying from slightly wavy to curly, is black, though children's hair in desert regions is frequently sandy, and facial and bodily hair is usually plentiful. The head is dolichocephalic or nearly so, with retreating forehead and deep excavation of the temporal region, deep-sunk eyes and the bridge of the nose receding beneath prominent eyebrow ridges. The lower part of the nose is splayed, the mouth wide, the lips usually thick, but not everted, and prognathism is common. Average male height is about 5 ft. 6 in., ranging from about 4 ft. 10 in. to a little over 6 ft., and the women's average is about 4 in. less. The build is linear.

Origin and Classification.—Three theories have been put forward.

Similarities of hair form and its distribution and certain features of the bony head structure suggested that the aborigines were archaic Caucasoids; *i.e.*, primitive Europeans. Further, the absence of definite evidence of throwbacks from consistent matings of descendants of European-aboriginal half-castes with Europeans was attributed to a common ancestral stock for both races; progressive dilution is the more likely and logical explanation. Blood-group analysis does not support the Caucasoid theory. Apart from Melanesian influence in the northeast, aborigines lack the B group, a regular European feature, and the S antigen, common in Europe (77%). Of the A group, there are 27%, western Europe's 45% and, of this 27%, all is A_1, whereas A_2, which is regular in Europe, is absent from Australia and, mostly, from the Pacific. Further, the aborigines' O-group frequency, 73% significantly exceeds that of western Europe which is under 50%. Finally, N is higher among them than elsewhere, whereas M and the Lutheran antigen are rare (*see* BLOOD GROUPS). If, the if aborigines and Europeans were archaically one stock, the

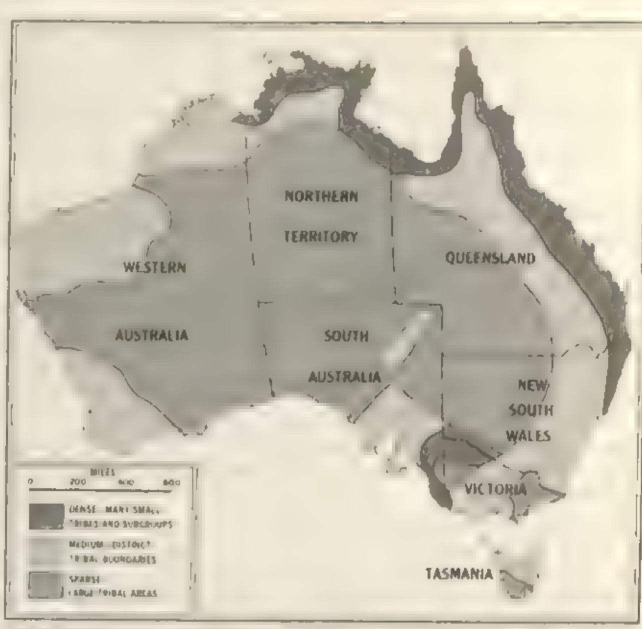
gence in blood has been remarkable. This is true also of the aborigines' fingerprint pattern, with its high frequency of whorls, differing completely from the Europeans'. Two other significant facts are: (1) the morphology of aboriginal facial musculature is highly undifferentiated; and (2) the external morphology of the aboriginal brain is marked by retention of very primitive forms (*e.g.*, of the intrastriate sulci) and by comparative underdevelopment of the new cortical areas.

J. B. Birdsell ascribed a trihybrid origin to the aborigines. The first occupants of the continent were Tasmanoids; *i.e.*, woolly haired, black Negritos. Next came stockily built, lighter-coloured Murrayians, with wavy to straight hair and with facial features "coarse and rough-hewn, but definitely Caucasoid in configuration." With their closest affinities to the Ainu, they were "related to some of the Upper Palaeolithic types of Europe." In Australia they remained in their least mixed form around the southeast and south. The third wave consisted of tall, linear and very dark Carpentarians whose general appearance was and is "extremely primitive, generalized and non-White." They are the true Australoid with closest affiliation to the Veddoids of Ceylon and southern India and are considered to be most clearly represented in northern and central Australia. All three stocks are said to have arrived in turn during the Fourth Glacial period by way of the Sahul shelf, which then joined New Guinea and northern Australia, and the aborigines are the result of their miscegenation in varying degrees. Thus, the archaic Caucasoids are only one element in the population and are distinguished from the later Australoids, while the crossing of the Negrito and archaic Caucasoid stocks accounts for the Tasmanians. These views have not been substantiated with sufficient data, and are not supported from blood analysis and fingerprinting. The differences in the aboriginal population can be explained by accepted biological processes without recourse to a triracial hypothesis, and the study of currents and winds shows that the Tasmanians could be the offspring of groups or a group drifting by canoe from Melanesia, probably the New Hebrides (a view with which physical anthropology can agree).

The third theory (held by E. Dubois, F. Weidenreich and A. Keith) is that the Australoids became differentiated in the Malaysian-Australian region, as indicated by the series *Pithecanthropus* (Java man), *Homo soloensis, Homo wadjakensis* and *Homo talgai* (southeast Queensland), all of which are fossils, and the Australian aborigines. They spread north and east to the Malay peninsula, southern India and Ceylon, and also east and south to New Guinea, Melanesia and Australia. Isolated in the latter, they retained their typical characteristics, whereas in New Guinea and Melanesia they were submerged by later waves of migrants with different blood group patterns.

Peopling of Australia.—The aborigines, whether in one or several periods, probably arrived either by way of the now submerged Sahul shelf or, where land connections were absent, by rafts and canoes. They brought with them the dingo, a species of dog. There are apparent surviving pockets of a common Australian language, not necessarily the original, in Cape York peninsula and northeast Arnhem Land. The aborigines were not gardeners and Australia provided no animals suitable for herding, so they lived by food-gathering and hunting, in which activities they were limited by distance from fresh water. With increase of numbers, subgroups set out to find other waters: "paths" of mythological heroes and "trade" routes indicate the directions of the migrations. The total population in 1788 was probably about 350,000, though some estimates have put the figure as low as 150,000, divided into about 500 tribes, each with its recognized territory and its distinct language or dialect, some of which developed marked differences. Archaeological research points to an occupation of probably 10,000 years or more.

Social Structure.—A tribe consists of several local groups which, food permitting, associate for most of the year. Each group, membership of which is in the male line, regards a particular part of the tribal territory as its country; *i.e.*, the country to which it belongs. Within it is a watering place where the group's ancestors originally settled and where the pre-existent spirits of



DISTRIBUTION OF ABORIGINES IN AUSTRALIA AND TASMANIA, 1788, YEAR OF THE FIRST EUROPEAN SETTLEMENT. TOTAL POPULATION OF ABORIGINES WAS ESTIMATED FROM 150,000 TO 350,000

its members are believed to have sojourned ever since, waiting for incarnation and reincarnation. Founders of secondary settlements and their descendants are forever kinsfolk of the primary group and its descendants, regardless of how far they are separated in space, time and customs. A system of classifying everyone as a relation codifies reciprocal behaviour based on recognized indirect kinship links (if any), on apparent generation level, on membership of clans or other social groupings and on ritual affiliation.

In much of Australia, relations are divided into two, four or eight groups (termed respectively moieties, sections and subsections), which are correlated with rules of marriage and descent and, like clans, are normally exogamous (*see* EXOGAMY). Such divisions serve to regulate kinship terms and behaviour especially in intertribal arrangements. Marriage is based on kinship. In a few tribes a man may marry his cross-cousin, *i.e.*, the daughter of his mother's brother or of his father's sister, but in most he may not marry anyone nearer than the daughter of his mother's or father's cross-cousin. The most widespread, preferred marriage is between persons classified as second-degree cross-cousins.

Adaptation.—The aborigines possess detailed knowledge of each tribal territory and when and where food can be obtained. This is summarized in the seasons, which vary from five to eight in different regions, each being marked by the normally expected climatic conditions and by the kinds of procurable foods.

Aborigines face the recurrence of droughts and food failures by regarding natural species and the rain as part of man's social and moral order and by entering into ritual relations with them. Each group within a tribe consists not only of men and women but also of several species, so that all are relations. The group (clan) bears the name of one of these, its totem (*see* TOTEMISM). The human members (totemites) do not injure or eat this totem or any other species of the group, unless in dire need and after due ceremony; on the other hand, the totem helps the totemites in waking life or in dreams by conveying information or by strengthening them when sick. Further, the men are divided into lodges, each of which is custodian of the mythology, ritual, sites and symbols associated with one or more natural species and with ancestral heroes. Through ritual re-enactment the creative past becomes operative in the present and the life of species and man is assured. The myths and ritual, usually called cult-totemism, are to the aborigines the "dreaming," signifying continuity of life unlimited by space and time. The initiation into cult-membership, which is open to men only, is a ritual form of death and rebirth or rising to life, an experience of passing from ignorance to a

conscious share in the "dreaming" and to an assurance of life. This is continued in the burial ritual, which varies in form in different regions and even in one region, but which always ensures the return of the spirit to its "dreaming," its spirit home, from which it will be reincarnated. Only the old men have full knowledge of the "dreaming" and therefore authority in ritual. This also gives them authority in matters of social behaviour, for the precedents are found in the behaviour and institutions of the ancestral heroes, but they actually apply the norms of customary behaviour, with which all are familiar.

Except in the case of infants and old persons, or when caused by a weapon, death is attributed to sorcery and only the medicine man, the "clever fellow," can extract the "badness" and restore confidence and the will to live. A psychic expert and a good psychologist, he comes in his "training" into association with the dead, with some totem spirits and with the sky-world. If he fails to cure, it is because he has been called too late, or the sorcery is too strong (as in fat and blood extraction), or the victim deserves his fate.

Culture.—Aboriginal myth and ritual are expressed in art, poetry, music and dance. The myths are preserved in chants which are poetic in expression, rhythmic in structure, linguistically interesting and musically significant. Sacred symbols and even weapons are painted and engraved to express myths, which are also chanted "into" them. The actors' bodies are painted in ritual, and mythological designs are engraved or painted on stone, painted on bark and even on the ground, the painting and engraving being themselves rites. Painting is also done for pleasure, just as singing and dancing take place at the camp-social corroboree as well as on the secret ground. There are regional schools of art and music and also regional differences in the form and decoration of implements and weapons. The content of some major religious cults also vary regionally.

(A. P. E.)

AUSTRALIAN ALPS, a term applied somewhat loosely to the mountain mass which occupies the southeasternmost corner of Australia (eastern Victoria and southeastern New South Wales). In a more local sense it denotes the ranges on the Victoria-New South Wales border forming the watershed between the Murray system and the Snowy and other rivers flowing directly to the Pacific. Strong vertical movements of the earth's crust have disrupted the original drainage to produce a pattern very complex in plan, well shown by the great fishhook bend of the upper Murrumbidgee. The term Alps as applied to these mountains denotes their general characteristics as massive and seasonally snow-clad highlands rather than their special structural features. In this latter sense they are not Alpine mountains but are a powerfully developed block massif composed of elevated areas and downfaulted areas. This Tertiary faulting affected a region of comparatively homogeneous topography and diversified it into a series of massive flattish uplands and comparatively roomy depressions. It was followed by a local glaciation (Pleistocene-Kosciusko Ice Age) which further emphasized the flatness of the summit topography. The result is an upper surface of broad undulating highlands upon which even the highest elevations (Kosciusko, 7,316 ft., the highest peak in Australia) are not distinctly remarkable. Because of the spasmodic nature of the uplifts the streams have worked out characteristic "valley-in-valley" forms. There are also evidences of extensive river capture.

The highlands are snow-clad in winter, though the timber line lies at 5,000 ft. and the area of alpine flora is small. The rocks of these highlands are extensively, if not richly, mineralized and a good deal of mining mainly in small and scattered workings (*e.g.*, Kiandra [altitude 4,640 ft.], the highest settlement in Australia) was once carried on. The valleys and basins and the lower uplands have been utilized mainly for pastoral purposes.

All development, however, is dominated by the Snowy hydroelectric project, a joint undertaking of the commonwealth and the two states. This scheme involves a complex system of dams and tunnels (one of them 35 mi. long) to divert water from the Snowy across the divide and so generate eventually at 16 power stations (the first of which was opened in 1955) about 3,000,000 kw. The project also adds considerably to the irrigation facilities of the Murray basin. New roads and construction camps have been built and the old rural service centre of Cooma, the main base, has been dwarfed by the boom town of its suburbs (pop. [1961] 8,716). In addition, this area was in 1960 becoming increasingly a national winter playground and health resort. *See* also AUSTRALIA, COMMONWEALTH OF.
(O. H. K. S.)

AUSTRALIAN CAPITAL TERRITORY, a separate political entity of the commonwealth of Australia, situated within the confines of the state of New South Wales and comprising the national capital of the commonwealth, Canberra, and some surrounding country. The site was selected in 1908–09 and the territory was turned over to the commonwealth by New South Wales in 1911. It lies on the Murrumbidgee river at the foot of the southern Alps and at an altitude of 1,900 ft. The population of the territory in 1954 was 30,315; its area is 939 sq.mi. Apart from the governmental, administrative, constructional and other activities of the capital city, there is some primary industry in the territory, mainly concentrated on wool and meat production, dairying and forestry. In 1915 the commonwealth also acquired from New South Wales sovereign rights over an area of 28 sq.mi. of land and water at Jervis bay for possible use as a port. *See* also CANBERRA.

AUSTRALIAN LANGUAGES, the languages spoken by the aboriginal inhabitants of the Australian mainland. The total number of aborigines in 1788 has been variously estimated from 150,000 to 350,000. N. B. Tindale's map locates almost 600 tribes. Geographical barriers and long isolation produced a great diversity of highly developed languages, the majority of which exist only in scanty vocabularies and grammars, often phonetically and grammatically inadequate, which were written largely by linguistically untrained missionaries, explorers and officials before 1930. By the 1930s, when trained linguistic research workers began their investigations, the native population was estimated to have decreased to somewhat less than 50,000 persons, and some languages and many dialects had become extinct.

No complete dictionary had been printed in any Australian language by mid-20th century; in only a few had adequate native texts been recorded.

The paucity and uncertainty of records of the Australian languages are such that statements concerning their characteristics and classification must be treated with reserve. There are two schools of thought: one sees grammatical features such as appear in inflected languages, and this seems to be the fact in some of the Australian languages; others deny this assertion, at least in the Aranda language and perhaps some others.

Phonetically, the Australian languages show great uniformity. Of the fricatives, only *v* and the velar fricative denoted by the phonetic symbol [γ] occur in isolated languages. The glottal stop is found in some northern languages. There is so little distinction between *p* and *b*, *t* and *d*, *k* and *g*, that some linguists assume the existence of only a single sound in each pair; viz., completely unvoiced *b*, *d* and *g*. Distinctions are made between dental, interdental and cerebral forms of *n* and *d* or *t*, also between dental and cerebral *r*, and several varieties of *l* sounds. A common sound is *ng*; it often begins Australian words. The *j*, which is pronounced as the "y" in "young," is frequently found in the combinations dj

or *tj*, *nj* and *lj;* and *w* is another common sound. The vowels *a, e, i, o, u* occur, but native speakers rarely preserve their exact shades.

Differing widely in grammatical structure, the Australian languages have certain features in common. There is great similarity in the word order. Two nominative case forms generally exist: first, the noun as the "name" (when followed by an intransitive verb), secondly the noun as the "agent" (when followed by a transitive verb). In many declension systems the cases are nominative, agentive, objective, possessive, ablative and locative, to which may sometimes be added a dative, instrumental and vocative. The adjective normally follows its noun. The personal pronouns, except in the Victorian languages, are built up out of different stems (as in the European languages). Numerals are always represented very poorly. In the verb, a reflexive voice, also a negative voice, may occur, but no passive. Postpositions replace the European prepositions. Some words are distributed over the whole continent; *e.g., mil* "eye," *kutara* "two," *mara* "hand."

These common phonetic and structural features suggest that the Australian languages may have developed from a common parent. No relationships between these languages and those of Papua, Melanesia, India or even Tasmania have been conclusively established on linguistic evidence. (*See* also PIDGIN; SLANG.)

MAIN LANGUAGE GROUPS

Prefixing Languages.—These stretch from near Broome along the Fitzroy river toward the Roper river and the Gulf of Carpentaria, covering the Kimberleys, Arnhem Land (except for its northeastern corner) and the top portion of the Northern Territory, also such northern islands as Groote, Bathurst and Melville. These languages stand out sharply because of their use of prefixes in the inflections of both nominal and verbal forms, whereas the remaining Australian languages use only suffixes for all flectional purposes. These prefixes are almost identical over the whole area, whereas the vocabularies of these languages show little resemblance. The agentive case is absent in the dual and multiple classifying languages. Some suffixing is found also in the prefixing languages. Incorporation of the pronoun objects into the verb is a second common characteristic. Some languages incorporate the noun object.

In most of the prefixing languages noun classification forms a further characteristic feature, permitting the following three divisions:

Multiple Classifying Languages.—These include Ungarinjin, Wunambal, Worora, Larakia, Kakadu, Anjula, Andiljaugwa. Here the noun classes vary from three to nine. The noun classes suggest the grammatical gender divisions of the European classical languages. This generally involves concord in the adjectives, numerals and pronouns.

One complex example is Andiljaugwa. This has nine noun classes; singular, dual, trial and plural are expressed by prefixes in its pronouns; transitive verbs incorporate the object pronouns; the verbs show many tenses and moods and also a separate negative conjugation.

Dual Classifying Languages.—Examples of this group are Gunavidji, Djerag, Worgaidj. Only two noun classes exist, corresponding roughly to a grammatical masculine-feminine division.

Nonclassifying Languages.—Examples include Iwaidja, Njulnjul and Rainbarngo. These conjugate the verb by prefixes and incorporate the pronoun objects, but lack noun classes.

Suffixing Languages.—These occupy the mainland south of the prefixing area; also Cape York peninsula and the northeastern corner of Arnhem Land with its adjoining lands. The following categories rest on the available printed material:

Western Desert Languages (Capell).—These are spoken over the huge arid area of central and western Australia, comprising probably one-third of the continent. The prefixing, southwestern peripheral and Aranda areas form the northern, western and eastern borders; and the Nullarbor plain marks the southern limit. Among the western desert languages are Garadjeri, Wolmeri, Julbre, Mudbura, Pitjantjara and Kukatja (better known as Loritja or Aluridja).

A practically uniform set of pronouns found throughout this area, and a distinctive verb conjugation are the characteristic features of these languages. In the Garadjeri group the root of the verb is either monosyllabic or a verbal noun conjugated by an auxiliary. Time, mood and person are indicated by the addition of suffixes to this root. A pronoun object may be added. In Pitjan(tja)tjara the suffixes indicating the personal pronouns may be appended to the first inflected word in the sentence, not merely to the verb root. Though allegedly one of the simplest Australian languages, Pitjan(tja)tjara has four declensions and four conjugations.

Southwestern Peripheral Languages.—These are the languages spoken in the peripheral coastal areas of southwestern Australia; *e.g.*, Pibelmen, Mineng, Whadjuk, Inggada. Many are extinct. Extant scraps of linguistic material indicate merely that these languages were distinct from those of the western desert tribes.

The Aranda Group.—The Aranda languages are found in the geographical centre of Australia, stretching from there northeastward across the Queensland border. Among them are the various Aranda dialects, Unmatjera, Kaititja, Iliaura, Jaroinga and others.

Aranda has case endings for five singular cases in the nominals (noun, adjective, pronoun). Dual and plural are normally expressed by the addition of *tara* "two" and *intjara* "many" respectively. When a noun is followed by the article, a pronoun, or an adjective, or a combination of several of these, such a group forms a nominal phrase, and the case endings are attached only to its last member. In the dual and plural forms of the first and second Aranda personal pronouns, distinctions are made linking them with the local sectional organization. In the verb a positive and a negative conjugation exist, each with an active and a reflexive voice. There are 4 tenses and 26 possible moods. Distinctions of singular, dual and plural are possible in each form. By means of reduplication and suffixes, up to 69 periphrastic verbs can be formed from the simple verbs, all capable of full conjugation. The sacred songs reveal the existence of a ceremonial language, characterized by many archaic words and a special poetic diction.

Victorian Languages.—This group includes most of the languages spoken in Victoria, also Jaralde (or Narrinyeri) in South Australia, and it stretches over into southern New South Wales. The area occupied reaches from the Murray valley to the southern coast. In these languages difficult and unusual consonant groups occur not only medially but also at the ends of words, and considerable use is made of suffixed pronouns. In their personal pronominal systems, person and number are normally expressed by pronominal suffixes attached to a common root, in sharp divergence from normal Australian practice. In the verb person and number are generally indicated.

Mixed Languages.—The mixed languages comprise the following:

The south-central group, which includes Pangkala, Dieri and the Darling river languages. The group stretches from the central portion of the south Australian coast into southwestern Queensland.

The north-central group, occupying most of southwestern and central Queensland. The north-central and south-central groups show evidence of a considerable mixture of the various Australian language types so far indicated. No real homogeneity is apparent.

New South Wales languages, which also form a very mixed group of languages. Among the best known are Kamilaroi, Wiradjuri and Gumbainggar. In Wiradjuri-Kamilaroi the dual and plural forms of the nouns are formed by adding the equivalents of "two" and "many" to the singular. In Wiradjuri, the possessive pronouns appear as suffixes attached to their appropriate nouns. In Gumbainggar the adjectives usually precede the noun and are inflected with it; prepositions precede the noun they govern.

Cape York and northeastern Arnhem Land group, among which

are the Wik- and Koko- languages of northern Queensland and the Murngin languages of northeastern Arnhem Land. In Wikmunkan there is incorporation of pronoun objects, and the adjective alone is declined when it qualifies a noun (as in Aranda). Wikmunkan and Kokoyimidir have no agentive case. The personal pronouns of Kokoyimidir and of the northern Murngin languages are similar to those of the western desert group. Murngin languages show agreement with the western desert languages in the objective and possessive case suffixes of their nouns.

BIBLIOGRAPHY.—W. Schmidt, *Die Gliederung der australischen Sprachen* (1919) and *Die Personalpronomina in den australischen Sprachen* (1919) indicate the older groupings. The former contains a full bibliography of the older linguistic sources. This has been continued to 1949 by Cestmir Loukotka in "Supplementary Notes to the Classification of Australian Aboriginal Languages," *Lingua Posnaniensis*, T. iii (1951). N. B. Tindale, "Distribution of Australian Aboriginal Tribes," *Transactions* of the Royal Society of South Australia, vol. 64 (I) (1940), contains a tribal map. Much research work has appeared in *Oceania* (published by Australian National Research Council) since 1930: A. Capell's classification of languages in Arnhem Land and Northern Australia, vol. 10 (1940), vol. 12–13 (1942); R. M. Trudinger, "Pitjantjatjara Grammar," vol. 13 (1942); U. H. McConnel, "Wikmunkan Phonetics," vol. 15 (1945); W. E. Smythe, "Gumbainggar Grammar," vol. xix–xx (1948–49). *Oceania* monographs are No. 3, *Studies in Australian Linguistics*, ed. by A. P. Elkin, and No. 7, *Aranda Phonetics and Grammar*, by T. G. H. Strehlow. *See* also J. Guiart in A. Meillet and M. Cohen, *Les Langues du monde*, pp. 691–710 (1952); A. Sommerfelt, *La Langue et la société* (1935). (T. G. H. S.; J. Wh.)

AUSTRALIAN LITERATURE. The history of Australian literature may be divided into four periods. Literature from 1788 to 1850 is mainly description by visitors, immigrants and native-born people of oddities produced by convict origins and the novel environment; the literature of the second period, from 1850 to 1910, is mainly an account of the way of life and values of the men and women in that pastoral and agricultural society; that of the third period, from 1910 to 1940, is the literature of the transition from rural to urban life; and in the fourth period, after 1940, literature reflected anxiety and doubt.

The Pre-Gold Period, 1788–1850.—The first period is much richer than the followers of a narrow nationalism admitted. The first fleet had men of literary talent among its officers. Two of them kept and published diaries of permanent value—D. Collins in *Account of the English Colony of New South Wales* (1798) and W. Tench in *A Narrative of the Expedition to Botany Bay* (1789) and *A Complete Account of the Settlement at Port Jackson in New South Wales* (1793). From 1788 to 1850 and even later the book of memoirs was the most usual form of literary expression. One of these was "A. Harris' " *Settlers and Convicts* (1847).

Another form in which men with literary gifts found expression was the political pamphlet. The distance from the seat of government, the contribution of the convicts to the wealth of the few and the morals of the many, the struggle for a secure title to the rich grazing lands of eastern Australia—all these provoked pamphlet wars, and some of these pamphlets are worthy of mention; *e.g.*, W. C. Wentworth's *A Statistical, Historical, and Political Description of the Colony of New South Wales and Van Diemen's Land* (1819), and J. Mudie's *The Felonry of New South Wales* (1837). Almost in the same category as the political pamphleteers are the early historians of the colonies of Tasmania and New South Wales. The two most important used history as political propaganda. J. West wrote his *History of Tasmania* (1852) as a supplement to his campaigns against the transportation system. J. D. Lang, an aggressive Presbyterian, published *An Historical and Statistical Account of New South Wales* (1834) as an apologia for his political campaigns against the British government, the squatters, the Irish and the pope.

Of poetry, novels and plays the first period was almost barren. Barron Field's *The First Fruits of Australian Poetry* (1819) is mentioned in histories of literature simply because it was the first. Charles Harpur (1813–68) used Australian themes, but he was a better writer of satirical prose than of poetry.

The Pastoral Period, 1850–1910.—The discovery of gold in 1851 had important effects on literature. Gold created a larger reading public; gold made Melbourne the economic and possibly the cultural centre of Australia; a generation after the discovery of gold, *i.e.*, by 1870, native-born Australians outnumbered the immigrants—the immediate occasion for the development of cultural chauvinism. Two poets of this period may be mentioned. Adam Lindsay Gordon (*q.v.*) used for his themes the everyday life of the Australian bushman. But although Gordon expressed the bushman's philosophy of resignation, he never became the bushman's poet. His contemporary, Henry Kendall (*q.v.*) also used material familiar to many—gum trees, the bush, the sea—but he wrote for the few.

Four prose writers made their mark at this time. The first was Henry Kingsley (*q.v.*), whose novel *The Recollections of Geoffrey Hamlyn* (1859) was an idyll of the squatter-gentleman from England who used Australia as a place to make money with which to return later to gracious living in England. The second was Marcus Clarke (*q.v.*), a gifted if wayward writer who poured forth a series of sketches, essays and short stories on the political and sectarian controversies of his day. By making extensive use of the material in the 1837–38 *Report of the Select Committee on Transportation*, and of the literary advice of Sir Charles Gavan Duffy, Clarke completed his indictment of the colonial system in his novel *For the Term of His Natural Life* (1874). Despite its wide popular appeal it is doubtful whether Clarke's work showed the understanding of the convict mind, or the literary ability of a less-known writer on the convicts, "Price Warung" (William Astley, 1854–1911) who published four collections of stories: *Tales of the Convict System* (1892), *Tales of the Early Days* (1894), *Tales of the Old Regime* (1897) and *Tales of the Isle of Death* (1898). The other prose writer of importance was "Rolf Boldrewood" (Thomas Alexander Browne, 1826–1915). He wrote one exciting story about bushranging, *Robbery Under Arms* (1888).

All these writers tended to accept the assumption that Australians as "colonials" were inferior to Englishmen. The federation movement was connected with the development of a nationalist literature in the last 20 years of the 19th century. The Sydney *Bulletin*, which began publication in 1880, provided a market for the nationalist writer. The result was a steady stream of distinctively Australian work, defiantly proud of the crudities, the coarseness, the vulgarity and the irreverence of Australians and confident in their doctrines of mateship and social equality for Australians and in their contempt for the rest of the world. The most important of these writers was Henry Lawson (1867–1922), author of *While the Billy Boils* (1896), *On the Track and Over the Sliprails* (1900) and *Joe Wilson and His Mates* (1901). Just as firm in his nationalism and belief in social equality but with a stronger intellectual content was "Tom Collins" (Joseph Furphy; *q.v.*). His three main works were: *Such Is Life* (1903), a rambling, discursive volume with a slender plot used as a peg for some brilliant discussions of the problems of Australia and of life; *Rigby's Romance* (published serially in 1905 and as a novel in 1921), a book with a slender plot, but valuable for its discussion of socialism and its knockabout humour; and *The Buln Buln and the Brolga* (first published in 1948), a nationalist allegory which contains some of the best slapstick comedy in Australian literature. The other aggressively Australian writer, "Steele Rudd" (Arthur Hoey Davis, 1868–1935), used comic relief as a poultice for the squalor of the lives of his characters—small farmers in Queensland. One writer who refused to use humour or idealism to relieve the gloom of her work was Barbara Baynton, whose important book was *Bush Studies* (1902).

By contrast with the skill and confidence of the prose, the poetry was disappointing. Lawson wrote from the heart, but rarely rose above the level of doggerel verse. Victor James Daley (1858–1905) had most success with his mordant political satires. Other poets were Dowell O'Reilly (1865–1923), Barcroft Henry Boake (1866–92) and Edward Dyson (1865–1931). During the same period, but quite unaffected by the noise and excitement of the nationalist movement, George William Rusden brought out his *History of Australia* (1883) and Gyles Turner published his *History of the Colony of Victoria* (1904).

The Urban Period, 1910–40.—In comparison with the optimism and the swagger of the works of the nationalist school, the

work of the third period seems pervaded by nostalgia, doubt and drabness. One reason for this was that economic changes had destroyed the unique conditions of bush life by 1910 and life in the big cities, which became the raw material for writers in the 20th century, was no different from life in industrial cities in Europe, the Americas or South Africa. The possible exception was the larrikin—the centre of Louis Stone's *Jonah* (1911) and Edward Dyson's *Fact'ry 'Ands* (1906). Different from other books of the period was a work whose main theme, the disintegration of a great character, could belong to any time or place—*The Fortunes of Richard Mahony* (1917–29), a trilogy by "Henry Handel Richardson" (*q.v.;* Ethel Lindesay Robertson). Her other works on Australian subjects were *The Getting of Wisdom* (1910) and *The End of a Childhood* (1934).

Two other women writers published important work during this period. One of them, Miles Franklin (1879–1954), did her best work by an imaginative, if nostalgic, recreation of the life of the pioneers of the Yass-Goulburn-Canberra-Brindabella districts; books of this class are *My Brilliant Career* (1901), *Old Blastus of Bandicoot* (1931), *All That Swagger* (1936) and *My Career Goes Bung* (1946). The other distinguished woman writer, Katharine Susannah Prichard (1883–   ), began her literary career as a warm-hearted, spirited teller of exciting stories, and moved slowly toward the social "message" of the spirit of the 1890s. Her books included *Working Bullocks* (1926), *Coonardoo* (1929), *The Roaring Nineties* (1946), *Golden Miles* (1948) and *Winged Seeds* (1950). "Brent of Bin-Bin" wrote a trilogy on the pioneers of the Canberra, Brindabella and Cooma districts.

Within this period the subjects and the methods of the novelists gradually widened. Mrs. Aeneas Gunn (1870–1961), published two moving accounts of the aborigines: *The Little Black Princess* (1905) and *We of the Never Never* (1908). Xavier Herbert published a brilliant though savage indictment of Australian behaviour to the half-caste in *Capricornia* (1938). Vance Palmer (1885–1959) wrote *The Swayne Family* (1934), a novel about the way of life and aspirations of a middle-class family in a Melbourne suburb. Eleanor Dark in *The Timeless Land* (1941) and *Storm of Time* (1948) used the historical setting of New South Wales from 1788 to 1808 as the medium for her sensitive conception of human relations and the relations between men and earth. Frank Dalby Davison wrote about animals in *Man-Shy* (1931) and *Dusty* (1946). Martin Boyd's witty and sophisticated books *The Montforts* (1928), *Lucinda Brayford* (1946), *The Cardboard Crown* (1952) and *A Difficult Young Man* (1955) discussed the great problem, for intellectuals and artists, of England versus Australia. Kylie Tennant (Mrs. L. C. Rodd; 1912–   ) published social satires. Gavin Casey (1907–   ), "Brian James" (1892–   ), Cecil Mann (1896–1967), Alan Marshall (1902–   ) and Dal Stivens (1911–   ) were the main writers of short stories.

Among poets Andrew Barton Paterson ("Banjo"; 1864–1941) won a wide audience with such ballads as "The Man From Snowy River" and "Waltzing Matilda"; C. J. Dennis (1876–1938) jerked many a tear with *Songs of a Sentimental Bloke* (1915). By contrast, men of talent received little attention from the public, though for the first time Australia had produced poets with technical equipment and maturity of outlook. These included Christopher Brennan (*q.v.*), Kenneth Slessor (1901–   ), R. D. FitzGerald (1902–   ), Frederick Macartney (1887–   ), Furnley Maurice (Frank Wilmot; 1881–1942), J. Shaw Neilson (1872–1942), Bernard O'Dowd (1866–1953) and William Blocksidge (William Baylebridge; 1887–1942).

The Period of Anxiety, After 1940.—The boundary between the third and the fourth periods is almost imperceptible. The expulsion of the European from south Asia and national and class wars stimulated, in some quarters, a reaction against the nationalism, the egalitarianism and the sentimentality to which the ideal of mateship frequently degenerated. This revolt was led by the poets and verse dramatists—a revolt which by the 1960s was still groping for a definition of values to substitute for the cheeky nationalism, the belief in material well-being for all, in equality and in "being mates." The most significant writers of this new age were the poets Douglas Stewart (1913–   ), Judith Wright (1915–   ), James McAuley (1917–   ) and A. D. Hope (1907–   ) and a novelist, Patrick White (1912–   ).

So the developments in literature corresponded roughly with the course of economic history. Like most new world literature, in the early period it was strong in narrative and humour, but rough in style and weak in intellectual content. Indeed, as late as 1960 the literature of ideas was still struggling for recognition in a society which seemed to be reluctant to drop the myth that the bush was the great creator in Australia.

AUSTRALITE: *see* TEKTITE.

AUSTRALOPITHECINE, creatures which, when first discovered in South Africa, were regarded as apes with manlike features of skull, teeth and posture but were later recognized as representing collectively that crucial phase in human evolution when the body posture had become erect but the brain was no bigger than that of living apes.

History and Nature of Finds.—R. A. Dart (1924) first gave the name *Australopithecus africanus*, or South African ape, to the fossilized skull, with its internal cast, of a six-year-old child blasted from the Buxton lime cliff at Taungs, Bechuanaland.

R. Broom in 1936 discovered adults in dolomitic cavern deposits, called bone-breccias, in Sterkfontein valley, 30 mi. W. of Johannesburg. Three sites near Johannesburg, Sterkfontein, Kromdraai and Swartkrans, proved so rich in jaws, teeth, skulls and other skeletal remains that parts of approximately 100 specimens of representative ages were found before Broom's death (1951). Broom distinguished three different genera, *Plesianthropus*, *Paranthropus* and *Telanthropus;* but Ernst Mayr (1950) contended that generic distinction is unwarranted and that all australopithecines belong to one species of earliest man: *Homo transvaalensis.*

From 1945 onward, at Makapansgat, nearly 200 mi. N. of Johannesburg, Dart recovered over 100 tons of bone-breccia containing a rich fossil fauna accompanying another form of australopithecine, *A. prometheus.* The outstanding characteristic of all australopithecines (apart from their small brains and erect stature) is their human dentition—especially the small nibbling front teeth (incisors and canines) as contrasted with the large grinding back teeth (premolars and molars).

In 1959, in the bed of the Olduvai gorge, Tanganyika, L. S. B. Leakey and his wife found an almost complete adult skull of yet another form of australopithecine, *Zinjanthropus boisei.* The contrast between the front and back teeth was most exaggerated and the skull was accompanied by stone implements. Stone implements had been reported previously in the upper Makapansgat breccia by C. K. Brain and C. van Riet Lowe in 1955 and in the upper Sterkfontein breccia by J. T. Robinson and R. J. Mason in 1957. At both sites australopithecine teeth accompanied the tools.

Robinson showed in 1953 that an upper-jaw fragment found by L. Kohl-Larsen near Lake Eyasi, Tanganyika, and called *Meganthropus africanus* by H. Weinert (1950), fell within the australopithecine range. He also claimed as australopithecine two lower-jaw fragments found by G. H. R. von Koenigswald between 1939 and 1941 at Sangiran, Java (Indon.), and called *Meganthropus palaeojavanicus.*

The *Gigantopithecus blacki* of Von Koenigswald—known first from fossil teeth bought in Hong Kong drug stores in 1935 and 1939 and attributed then to a "giant orang"—was found by Pei Wen Chung and his helpers in 1956 to belong to another intermediate, cave-inhabiting, hunting type which the Chinese anthropologists still regard as anthropoid but which Broom (1939 and 1946) and Von Koenigswald (1952) have recognized to be hominid. The three lower jaws found came from two bone-bearing but geologically distinct Pleistocene faunal levels, the older one regarded by the Chinese scientists as being of Villafranchian antiquity, in a cave on Lêng-Chian-Shan, a mountain in Kwangsi province in southern China.

Apparently the old world from southern Africa to eastern Asia was inhabited by diversified australopithecine human types followed successively by pithecanthropine and neanderthaline types before *Homo sapiens* appeared.

Dating.—The fossil faunas accompanying australopithecine remains are classified as of the Villafranchian epoch. Until the International Geological congress of 1948, fauna of the Villafranchian type were associated with the late Pliocene epoch. By attaching Villafranchian deposits instead to the subsequent, early Pleistocene epoch, the congress probably trebled the length of the latter period. According to the recent potassium-argon isotope dating technique, the Pleistocene began 1,000,000 or more years ago.

Significance.—The australopithecines have afforded substantial support of Charles Darwin's theory that man evolved and that Africa was probably his cradle. From the vast areas of the African and Asiatic continents over which they ranged and the extensive time lapse they flourished, it is not surprising that the australopithecines diverged in dental and other characteristics so greatly, nor that discussion of their exact zoological relationships to one another and to other human beings, whether varieties, species or genera of mankind, continued. For example, it was being debated whether remains found in the 1960s at Olduvai were australopithecine, or represented a new species *Homo habilis*.

Their discoverers (*e.g.*, Dart at Taungs and Makapansgat, Broom at Sterkfontein, the Leakeys at Olduvai and Pei at Lêng-Chian-Shan) have agreed that these intermediate forms were hunters of animals upon which they mainly lived and with whose bones their own remains have been found. Some scientists, however, still retain the view originally promulgated by Dean Buckland (1822) that broken bones found in caves were all carried into them haphazardly by carnivorous beasts, especially hyenas.

Others following Dart believe that a great many of the bone, tooth and horn-core objects found on australopithecine sites were utilized as tools after being split and pounded in human fashion and even made into utensils by australopithecines. No admitted stone tool having been found hitherto in the lowest strata at Makapansgat, these observers believe man's earliest stone cultural phase was preceded by this kind of osteodontokeratic (bone, tooth and horn) cultural phase. *See* also Africa: *Archaeology: Fossil Hominid Remains;* Man, Evolution of: *Australopithecinae.*

AUSTRASIA (sometimes also Austria), in the Merovingian period of French history, was the eastern Frankish kingdom as distinct from Neustria (*q.v.*), the western. The name, derived from a Germanic word meaning east, first occurs in the *Historia Francorum* of Gregory of Tours, in a passage dealing with the year 577. Austrasia then meant what had been the kingdom of Clotaire I's son Sigebert I (*q.v.*), covering the north and northeast of Gaul and spreading into Germany. Originally, however, the Romance areas of Aquitaine and Provence were also attached to the kingdom, so that the individuality of Austrasia, with its largely Germanic population, did not emerge clearly until the dukes of Aquitaine had made themselves virtually independent.

Clotaire II, king of the Franks, gave his son Dagobert to the Austrasians as their separate king in 623, and Dagobert, after succeeding to his father's kingdom, gave them likewise his own son Sigebert in 634. From then onward the kingdom had its capital at Metz and its own mayor of the palace, who after Dagobert's death in 639 became increasingly important (*see* Mayor of the Palace). The mayoralty of Austrasia was held by Pepin I and Grimoald, ancestors of the Carolingian dynasty, and after Pepin II had secured it for himself it remained in the family's possession, passing from father to son.

In the 7th century Neustria, in combination with Burgundy, was long successful in contesting Austrasian influence and was the dominant power until Pepin II's victory at Tertry in 687 assured the final ascendancy of the Austrasian mayors over the Frankish monarchy. In 751 Pepin III, the Short, deposed the last Merovingian king, Childeric III, and was himself elected king instead. Under the Carolingian dynasty royal authority was restored in France and an intellectual renaissance took place after the long decadence of the Merovingian period. *See* France: *History.*

AUSTRIA (Bundesrepublik Österreich), for centuries the core of a multiethnical state of central Europe (*see* Austria, Empire of and *History* below), became a German-speaking state on its own on Oct. 30, 1918. From March 13, 1938, until the end of World War II it was incorporated by Adolf Hitler into his greater Germany. On April 27, 1945, a new provisional Austrian government was formed and, following a general election, it was, on Jan. 7, 1946, recognized by the four Allied powers, though Austria remained under military occupation, divided into four occupation zones. On May 15, 1955, the four powers signed at Vienna a state treaty with Austria which recognized and guaranteed the latter as "a sovereign independent and democratic state" and terminated its military occupation. By an act of parliament on Oct. 26, 1955, the day after the last foreign soldier had left Austrian soil, Austria declared itself a permanently neutral state. It did, however, join the United Nations (elected on Dec. 15, 1955).

Austria lies between latitude 46° 22′ and 49° 1′ N and longitude 9° 32′ and 17° 10′ E. Its area is 32,374 sq.mi. (83,849 sq.km.), its greatest extent (along 47° N) is 360 mi. (580 km.), its narrowest section is only 18½ mi. (30 km.). Its national boundary (total length 1,639 mi. or 2,637 km.) in the northeast toward Czechoslovakia largely follows the watershed between the Danube and the Vltava and then the March (Morava) River; in the east toward Hungary, it runs in the Hungarian plain and the Alpine foothills; in the southeast, toward Yugoslavia, it is formed by the Mur River, the watershed between the Mur and Drau (Drava) rivers, and then the crest of the Karawanken and Karnische Alpen. It continues westward toward Italy along the main crests of the Central Alps and toward Switzerland and Liechtenstein along the Silvretta Gruppe and Rhätikon mountains and then the Rhine. The boundary toward Germany follows the Northern Limestone Alps and the Salzach and Inn rivers.

This article contains the following sections and subsections:

I. PHYSICAL GEOGRAPHY

1. Geology and Geographical Regions.—While about two-thirds of Austria is formed by the Eastern Alps, it also includes part of the Bohemian massif, so that nearly three-quarters of its surface is mountainous. The hilly or lowland regions consist of the Northern Alpine foreland, the Vienna basin and Eastern lowland, and the Southeastern Hill country.

The Eastern Alps.—These stretch from a western boundary, running from Lake Constance via the Rhine and Splügen Pass to Lake Como, eastward to the Vienna woods (Wiener Wald) and the hills of eastern Austria which form a link with the Carpathians. They are lower in altitude than the Western Alps and gain in width but gradually decrease in altitude eastward, thus the easternmost parts were never subject to glaciation. In contrast to the Western Alps, faulting in addition to folding played a greater part in their formation and they have a more regular lithological arrangement. They can be divided into three principal parts: (1) the Central; (2) the Northern; and (3) the Southern Alps, separated from each other by structural longitudinal troughs (the line Arlberg Pass, Tirolese Inn Valley, upper Salzach, Enns, Mur, and Mürz valleys, Semmering Pass, dividing the Northern from the Central Alps, and, within Austria, the Drau [Drava] Valley separating the latter from the Southern Alps).

The Central Alps consist mainly of a granite or gneiss core with a mantle of Paleozoic crystalline schists. These rocks weather relatively easily and except at high altitudes or around the cirques of the Quaternary glaciers they give rise to gentle forms covered with a thick layer of debris and soil and support extensive summer pastures and forests. The chief mountain groups of the Central Alps are, from west to east: the Silvretta Gruppe, Ötztaler Alpen and Stubaier Alpen, and, after the much lower section containing the Brenner Pass, the Zillertaler Alpen and the Hohe Tauern with Austria's highest peak, the Grossglockner (12,457 ft.; 3,797 m.). These groups have extensive glaciers, the largest in Austria being the Pasterzen Kees (of the Grossglockner) which is 6 mi. (9 km.) in length. East of a line from the source of the Enns River to Spittal an der Drau the Central Alps split into two branches: the northern consisting of the Niedere (low) Tauern and some other groups (Gleinalpe, Fischbacher Alpen, Wechsel) stretching toward Wiener Neustadt and Bratislava in Czechoslovakia, and a southern group of the Gurktaler Alpen and Seetaler Alpen and Koralpe, ending at Maribor in Yugoslavia.

The Northern Alps border directly on the Central Alps only in the extreme west of Austria, otherwise they are separated from each other by a narrow zone of Paleozoic rocks, shales, porphyry, or graywacke of low altitude. This zone forms separate mountain groups only east of the Brenner Pass (the Tuxer Gebirge and Kitzbühler Alpen) and north of Leoben (the Eisenerzer Alpen).

The Northern Limestone Alps, which follow the northern graywacke zone, are in the western part shared between Germany and Austria, whereas the eastern part lies entirely within Austria. They consist of Mesozoic limestone, the highest mountain groups being formed of Triassic rocks. In the west, the Lechtaler Alpen and Tirol Limestone Alps are of chainlike character with numerous glacial cirques, while farther east in the Salzburg Alps, the Salzkammergut Mountains, and the Upper and Lower Austrian Limestone Alps, massiflike mountain groups with extensive plateau surfaces prevail. Where the surface is formed of pure limestone it is barren and riddled with karst (*q.v.*) features with underground drainage and numerous caves. The name Totes Gebirge ("Dead Mountains") in the Salzkammergut reflects their barren appearance. Where the surface is of dolomite, as in the Limestone Forealps, they are largely wooded or covered with summer pastures (*Almen*). Because of their lower altitude and ruggedness there are only a few glaciers. The Hochkönig, in the Salzburg Alps, is capped by a plateau glacier and there are valley glaciers on the Dachstein Gruppe in the Salzkammergut Alps.

To the north the Limestone Alps are fringed by a zone of late Cretaceous to early Tertiary sandstone, the so-called Flysch. Only in the extreme west and east does this give rise to mountain groups with names of their own, the Bregenzer Wald and the Wiener Wald respectively. North of the Tirol Alps this zone lies outside Austrian territory. The Flysch zone reaches its greatest altitudes (up to 5,500 ft.; 1,680 m.) in the Bregenzer Wald, the name Wald ("wood") being only applicable historically as most of its heights were cleared for meadows and pastures. (*See* ALPS.)

The Southern Alps.—The equivalent to the northern zone in the south is more limited in extent and is largely represented by the Karnische (Carnic) Alpen and by part of the Karawanken. The separation between the lithological zones is, however, less clear cut in the south and is further complicated by the interposition of the Klagenfurt basin, the largest of the interior basins within the Austrian Alps. In the south the graywacke zone is followed and intermixed with the Southern Limestone Alps.

The Bohemian Massif or Austrian Granite Plateau.—This is geologically the oldest part of Austria and belongs to the Hercynian mountain system. It rises steeply from the Alpine foreland and forms an undulating surface occasionally overtopped by rocky crags and covered by block fields with raised bogs in between. In its eastern part it is well wooded. Generally the Danube forms its southern boundary, but in a few cases it separates some outliers by gorges. Of these the Wachau, between Melk and Krems, is the most famous and with its vineyards and ruined castles rivals the Rhine gorge.

The Northern Alpine Foreland.—This stretches from the border along the Salzach and the Inn rivers. On the whole gently undulating, it rises only in the forested Hausruck to 2,500 ft. (760 m.). Otherwise the surface is largely made up of more recent material: ground moraines and terminal moraines giving rise to hills and enclosing lakes in the southwestern part as far east as the Enns River and, to the north and east of that, gravel sheets and terraces consisting of the glacial outwash partly covered by the valuable loess, deposited by the

FIG. 1.—RELIEF MAP OF AUSTRIA

wind in the last glacial period. The base rock, a fine-grain impermeable marl, comes to the surface only in the lowest parts, though it reaches a thickness of over 3,000 ft. (900 m.). It contains iodine and thermal wells, natural gas, and oil (discovered in 1959 near Ried). There are extensive lignite fields. The woodland which formerly covered the Alpine foreland is now limited to three forests on the poorest gravel soils.

The Vienna Basin and the Eastern Lowland.—These continue the Alpine foreland eastward and are similar in character. The northern part between the Granite plateau and the March (Morava) River is a hilly country of 650 to 1,300 ft. (200 to 400 m.) in height occasionally overtopped by Jurassic hills 300 to 650 ft. higher. Structurally it is divided by a fault (running southwest to northeast) and its eastern section is geologically part of the Vienna basin. There the base rock has been much fractured and downfaulted to great depths. The northern Vienna basin contains Austria's major oil and natural gas fields. The surface consists of gravels and sands widely covered by loess, the basis for arable cultivation and viticulture.

The southern part of the Vienna basin forms an embayment also in a morphological sense. It extends in a triangular shape toward the Semmering Pass and is bounded in the west by the steep edge of the Limestone Alps which end in a fault line. This is known as the thermal line because of the many spas which are located there. The eastern boundary of this so-called Vienna Bay is formed by the wooded Leitha Mountains, an uplifted horst. The downfaulting of the Vienna basin began in Miocene times. First a fresh-water lake, it later became part of the Miocene sea, and then land again during the Pliocene period. In this process brown coal was formed. More important economically is the Miocene Leitha limestone which is widely used as building material. During the Ice Age great amounts of gravels were deposited in the southern part, which now support only pinewoods and heath.

The lowland east of the Leitha Mountains has a character of its own. Dominated by the Neusiedler Lake (*q.v.*), with its grazing areas to the east and its wells, it resembles the Hungarian *puszta*. On the eastern slopes of the Leitha Mountains and the shores of the lake there are extensive vineyards.

The Southeastern Hill Country.—Like the northern part of the Vienna basin, a structural though not a morphological basin, the Southeastern Hill country is the last of the physical regions. Formed at the same time as the Vienna basin, the faulting there resulted in volcanic activity. There are also many warm and mineral springs. During Pliocene times the basin was filled with gravel, and brown coal also was formed. But, since there the uplift continued longer, the Pliocene gravel sheet became heavily dissected by the rivers which cross it in gorges up to 300 ft. (90 m.) deep.

2. Climate.—Austria's climate is determined by its location and by its relief. The Northern Alpine foreland and the Granite plateau, dominated by Atlantic influences, are characterized by a moderate mean annual range of temperature of 38° F (21° C) and precipitation in every month with a maximum in summer and a minimum in February and March. The amount of precipitation varies on an average between 24 and 60 in. a year, depending on the relief and nearness to the Alps. Eastern and southeastern Austria have a more continental climate characterized by a greater (mean) annual range of temperature, of up to 41° F (23° C) and a smaller amount of precipitation ranging between 18 and 40 in. (45 to 100 cm.) depending on relief. The rainfall maxima occur from May to August.

The climate of the Alps has some peculiar features of its own. Normally the temperature decreases for every 1,000 ft. (300 m.) rise in altitude by 3° F (1.7° C), but during the winter air drainage can cause a temperature inversion in the Alps. While deeply incised valleys and basins are in the grip of heavy frost the mountains above experience much higher temperatures, which in the sun may approach summer values. For that reason the mean annual range of temperature in the interior basins and valleys with their hot summers is greater than either in the north or the east, whereas that of the peaks is considerably smaller (Sonnblick, 10,187 ft. (3,105 m.), range 26° F (14.4° C). In addition on the peaks the maxima and minima occur later adding a further oceanic touch to their climate. There is no absolute parallel between altitude and amount of precipitation. The effect of the mountains in increasing precipitation is very pronounced in the marginal northern chains, but it is not continued by the further rise in altitude toward the Central Alps, and some sheltered interior basins and valleys have only 24 in. (61 cm.), thus necessitating irrigation. Maximum rainfall occurs during the summer months except in the Gail and upper Drau valleys where an autumn maximum betrays Mediterranean influences.

A further characteristic of the Alpine climate is its winds. During high-pressure weather winds that blow along the valleys are a regular feature. Of greater importance, however, is the föhn, a warm and extremely dry south wind. It is caused by a depression passing north of the Alps and is of great force, often causing damage, but it speeds the melting of the snow. It is particularly felt in the Tirolese Inn Valley, where it enables maize to be cultivated.

3. Vegetation and Animal Life.—The lower parts of the Alps, the Northern Alpine foreland, and the Granite plateau share the middle European (or Baltic) type of vegetation. These regions were formerly covered by continuous high forests: deciduous trees, especially beech at the lowest altitudes, followed by mixed forests and spruce woodland higher up, intermixed toward their upper limit with larch and stone pine. The lower slopes have been largely cleared for agriculture. Many of the native animals of this zone have either disappeared, such as the boar, bear, wolf, and lynx, or have become much rarer, as have red and roe deer. Hares, squirrels, and martens, and, among the larger birds, blackcocks, hazel hens, hawks, buzzards, sparrow hawks, and pheasants are still frequent.

The eastern parts of Austria also were originally largely forested, the prevailing trees being pubescent oak, hornbeam, and sweet chestnut. Fairly large areas of these, in the form of brush and scrubwood, still cover the eastern hills. Where they have been cleared arable cultivation, fruit growing, and viticulture have taken their place. Pine forests cover extensive areas on the poorer soils. In the Neusiedler Lake area and on dry soils near Vienna the natural vegetation cover is of a steppe type (*Steppenheide*). Characteristic animals are the hamster and, in the riverside woods of the Danube and the shores of the Neusiedler Lake, there are numerous water birds, storks, herons, wild geese and ducks, and many others.

The highest parts of the Alps have their own flora. Above the upper limit of forest dwarf pines certain willow species and various low shrubs like the alpine roses, cranberries, and bilberries are interspersed with natural meadows. At greater altitudes, where vegetation becomes intermittent, there are cushion plants and rare species like the edelweiss, while at the greatest altitudes only algae, lichens and mosses are found. Of the characteristic alpine animals the ibex has become very rare and is now only found in a few preserves but the chamois is still frequent. The marmot has to be protected to prevent its extinction. The ptarmigan is still common but the golden eagle is now rare.

The forests and their animals, most of whom enjoy a closed season to ensure their survival, are looked after by foresters. Many rare plants and animals, especially numerous bird species, are protected absolutely. There are also areas conserved for their outstanding beauty, and smaller areas, about 40 in all, have been designated nature preserves and may only be entered with special permission.

II. THE PEOPLE

1. Ethnology.—Austrians are on the whole a mixture of the Dinaric and Nordic and to a lesser extent east Baltic and Mediterranean types. Pure representatives of a single race, even in mere appearance, are rare. Ethnically about 98% of the Austrians are German, and the German language is understood even within the small non-German areas. Although the Austrian usage of German has a number of common characteristics, the differences between the dialects of one area and another are considerable. Most of these local dialects belong to the Bavarian group except for those spoken in the west which belong to the Alamannic group. Accord-

ing to the 1951 census, there were about 74,000 Austrians who habitually spoke Croatian, Slovene, Hungarian, or Czech either exclusively or together with German. The Croatian minority, which is the largest group (34,000), is almost exclusively located in the Burgenland; they do not form a compact group but live in a number of villages separated from each other by German-speaking areas. The Slovenes form the second largest group (24,000). They are concentrated in southern Carinthia (Kärnten), but nearly half their number give German as their first choice of language. The other groups are smaller. There are about 11,000 Hungarians, mostly in three districts in the Burgenland, and about 5,000 Czechs, largely in Vienna.

2. Religion.—In religious denomination the Austrian people are nearly as homogeneous as they are ethnically. According to the 1951 census 89% were Roman Catholic, 6.2% Protestant and 3.8% of no denomination. The Jewish element (200,000 in 1934 and 11,000 in 1951) is almost exclusively located in Vienna and the Protestant group also has its largest concentration there, though there are small Protestant communities in the Burgenland, Carinthia, Styria (Steiermark), and Upper Austria (Oberösterreich) which were established before the Counter-Reformation. The Roman Catholic Church divides Austria into two main parts under the archbishops of Vienna and Salzburg, and Roman Catholicism is still a potent political factor.

3. Settlement.—The type of settlement depends on the way in which individual farmsteads are associated with each other. In the Alps, except in the larger valleys and in the Northern Alpine foreland, farmsteads are irregularly scattered (*Einzelhöfe*) and are compact farms; *i.e.*, have all their land in one piece. As a result of division of holdings up to five farmsteads may form an irregular hamlet, a *Weiler;* this is the prevailing type in the Bregenzer Wald. In the larger valleys of the Alps and in eastern Austria the dominant type of settlement is the village. West of the Enns River they are generally very irregular in their ground plan; these are the *Haufendörfer*. East of the Enns River, in the formerly Slavic areas colonized since approximately 1000 A.D., the villages are much more regular. Street villages (*Strassendörfer*) of great length, or variants of these where the street widens to a central village green (*Angerdörfer*), are characteristic. Where farms are grouped together in villages the land is usually divided into many individual parcels. (K. A. S.)

III. HISTORY

For Austrian history prior to 1918 *see* AUSTRIA, EMPIRE OF.

1. Deutschösterreich.—On Oct. 21, 1918, the German members of the imperial parliament (*Reichsrat*) of Austria formed themselves into a national assembly for Deutschösterreich or German-Austria; and on Oct. 30 they proclaimed this an independent state under the direction of a state council (*Staatsrat*) composed of the leaders of the three main parties and other elected members. Revolutionary disturbances in Vienna and, more important, the news of the German revolution forced the state council on the republican path. On Nov. 12, the day after the emperor Charles's abdication, the national assembly resolved unanimously that "German-Austria is a democratic republic" and "German-Austria is a component part of the German republic." Karl Renner (*q.v.*), a leading Socialist, became head of a coalition government with Otto Bauer (*q.v.*), the acknowledged spokesman of the left wing of the Social Democrats, as foreign minister. On Nov. 22 a further law defined the territory of the republic. The national assembly claimed the provinces with a majority of Germans in their integrity; it also claimed the German areas of Bohemia and Moravia.

The greatest danger to the new republic seemed to be Bolshevism, especially when a Soviet republic was established in Hungary at the end of March 1919. The Austrian Social Democrats were determined to resist Bolshevism with their own forces, not to make an alliance (as the German Social Democrats did) with the old order. Julius Deutsch organized the *Volkswehr* ("People's Guard"), and this was twice effective (April 17 and June 15) against Communist attempts at a *Putsch*. Otto Bauer and Friedrich Adler staked their popularity on defeating the Communist agitation in the workers' and soldiers' councils, which had been set up on the Soviet model. By mid-1919 Communism had been defeated, and a Communist party never raised its head again in the days of the republic.

More dangerous was the tendency of the provinces, or states, to break away from Vienna or to claim almost complete independence. Though the principal motive of this was reluctance to send food supplies to Vienna, it represented also a genuine feeling that, with the fall of the Habsburg (*q.v.*) dynasty, nothing higher than the province remained. Vorarlberg voted for union with Switzerland in May 1919, and Tirol attempted to secede also. In February 1919 elections for a constitutional assembly were held, and when this assembly met (March 4), it had to make wide concessions to federalism in order to appease the provinces; in exchange Vienna (hitherto part of Lower Austria) was also elevated to the rank of a state, with the mayor as equivalent to state governor. This proviso subsequently enabled "red Vienna" to pursue an autonomous policy despite the existence of a non-Socialist government—a result not foreseen by the Socialists, who were the strongest supporters of unitary government on orthodox Marxist lines. The territory acquired from Hungary (*see* below) was also formed into a separate state, Burgenland, thus making nine states in all.

The constituent assembly also settled the constitution of the federal republic (Oct. 1, 1920). The state council was abolished and a bicameral chief legislative assembly, the *Bundesversammlung*, was established. The upper house or *Bundesrat* (federal diet) was to exercise only a suspensive veto and was to be elected roughly in proportion to the population in each state (this represented a defeat for the federal elements in the states, which had wanted the *Bundesrat* to exercise an absolute veto and to be composed of equal numbers of members from each state). The lower house or *Nationalrat* (national diet) was to be elected by universal suffrage on a basis of proportional representation. The *Bundesversammlung* in full session elected the president of the republic for a four-year term, but the federal government, with the chancellor at its head, was elected in the *Nationalrat* on a motion submitted by its principal committee, this committee being itself representative of the proportions of the parties in the house.

2. Republic of Austria.—The programs of the major political parties and, especially, the foreign policy of Otto Bauer insisted firmly on *Anschluss* ("union with Germany"), but article 88 of the peace treaty of St. Germain (*q.v.*), signed on Sept. 10, 1919, forbade *Anschluss* without the consent of the League of Nations and also stipulated that the republic should cease to call itself Deutschösterreich (German-Austria). The republic was, however, treated as the heir of the Habsburgs and saddled with payments of reparations (which were never paid). The German-speaking areas of Bohemia and Moravia had to be ceded to Czechoslovakia. The southern frontier with Yugoslavia was threatened by Yugoslav armed invasion. As the population of the disputed area put up a stiff resistance despite opposition by the central government in Vienna, it was finally decided that the question should be settled by a plebiscite; this, when held (Oct. 10, 1920), returned a majority of 59% in favour of Austria. The German-speaking districts of western Hungary were to be ceded to Austria outright; but Austria was obliged to hold a plebiscite in the face of Hungarian resistance, and Sopron was finally restored to Hungary.

In the elections of February 1919 for the constituent assembly the Social Democrats, under Karl Renner, had been returned as the largest single party, with 69 seats against 63 won by the Social Christians and 26 won by the German Nationalists. Renner had then formed another coalition government, but he was obliged to resign in June 1920. A new cabinet was formed in July under the premiership of Michael Mayr, a Social Christian, with Renner as foreign minister. In the elections of Oct. 17, 1920, the Social Christians gained 82 seats, the Social Democrats 66 and the German Nationalists 20. Mayr remained premier and also took the portfolio for foreign affairs. In December 1920 Michael Hainisch became the first president of the republic. The political composition of Austria was now stabilized and no decisive change took place during the following years. Moreover, the accurate system of proportional representation, though it did not (as in other countries) encourage a multiplicity of parties, combined with the ideo-

logical background of Austrian parties to lessen oscillations of membership in the assembly. Of the two mass parties which the republic had inherited from the Habsburg monarchy, the Social Democrats had an unshakable majority in Vienna (in which about a third of all the inhabitants of the republic lived), while the Social Christians had an equally unshakable majority among the conservative-Catholic peasants. The former "imperial" classes (army officers and landowners) usually became Social Christians, though the program of the party was as demagogic as that of any party of the masses. The urban middle classes, hostile to both workers and peasants, became German Nationalists. But German nationalism was not limited to the middle classes. The workers and even the peasants felt themselves to be Germans and would also respond to the national appeal—as a series of unauthorized plebiscites held in the western provinces in 1920–21 clearly demonstrated by their overwhelming majorities in favour of an *Anschluss*.

The main task of the non-Socialist governments in power in Austria from autumn 1920 was to restore financial and economic stability. Between 1919 and 1921 the urban population of Austria lived largely on relief from the United States and Great Britain, and, though production improved, distress was heightened by inflation which culminated in financial collapse in 1922. In October 1922 the chancellor, Ignaz Seipel (*q.v.*), negotiated the Geneva protocols, securing a large loan through the instrumentality of the League of Nations, which enabled Austrian finances to be stabilized. In return Austria had to undertake to remain independent for at least 20 years. The controller general appointed by the League of Nations reported in December 1925 that the Austrian budget had been balanced satisfactorily, and in March 1926 the international financial control was withdrawn.

Seipel's success in October 1922 gave Austria some years of stability and made economic reconstruction and relative prosperity possible. In Socialist-controlled Vienna, during the years that followed, an ambitious program of working-class housing, health schemes and adult education was carried out, giving "red Vienna" a unique reputation in Europe. These schemes were financed principally by heavy taxes on property in Vienna, which virtually eliminated private income from house rents.

In 1920 all three major parties spoke in democratic terms. Despite democratic phrases, however, preparations for civil war had never been abandoned. The Social Christians, led by Seipel, who believed in strong government, were convinced that they had to protect the existing social order against a Marxist revolution. The Social Democrats felt their social reform program endangered by reactionary tendencies. The Social Democrats, moreover, had their own armed force, the *Schutzbund*, descended from the People's Guard of 1918. In the provinces reactionary forces, originally formed for defense against the Yugoslavs or merely against internal disorder, gradually took on the general description of the *Heimwehr* ("home defense force"). The Social Democrats and the reactionary forces regularly demonstrated against each other, and these demonstrations sometimes led to conflict. In 1927, in the course of a clash between *Schutzbund* and "front fighters" at Schattendorf, an old man and a child were accidentally shot by the "front fighters." When the "front fighters" were acquitted by a Vienna jury on July 14, the Social Democrats called for a mass demonstration. This took place on July 15, but got out of hand and ended in the burning down of the ministry of justice. In street fighting between the police and the demonstrators almost 100 persons were killed. The Social Democrats then launched a general strike, but this had to be called off after four days. Seipel had used the opportunity for a violent assertion of authority. The balance between Socialist and non-Socialist forces in Austria was never secure after this decisive date.

The Social Christians, increasingly pressed by the *Heimwehr*, now began to take the offensive against the Social Democrats. Wilhelm Miklas, a leading Social Christian, was elected president as successor to the nonparty Michael Hainisch. There were repeated attempts to revise the constitution, principally with the object of strengthening the power of the executive. After protracted negotiations, in view of the worsening economic situation, a compromise was reached late in 1929. On Dec. 7, 1929, a series of constitutional amendments gave increased powers to the president, especially that of appointing ministers and of issuing emergency decrees; on the other hand Vienna preserved its autonomy, and the democratic principle was preserved against the far-reaching authoritarian demands of the *Heimwehr*. In the elections of November 1930 the Social Democrats were returned as the largest single party with 72 seats, the Social Christians held 66, the German Nationalists 19 and the *Heimwehr* (now posing as a fascist party on the Italian model) 8.

These political events were overshadowed by the great economic crisis. Though the Social Democratic leaders believed that the crisis should be met by the orthodox means of deflation and economy, they were resolved not to be compromised by supporting these measures and refused to enter a coalition government. On the other hand, in October 1931 they acquiesced in suspending the election of the president by direct popular vote, as had been provided by the constitution of 1929, and agreed to the re-election of Miklas by parliament for a further four years. Meanwhile the government, led by Otto Ender and Johann Schober (*q.v.*), was driven to desperate devices in order to stave off collapse. Schober, leader of the middle-class German Nationalists, launched the project for a customs union with Germany in March 1931; this provoked violent opposition from France and the Little Entente (Czechoslovakia, Yugoslavia, and Rumania) and was subsequently condemned by a majority of The Hague court. The bankruptcy of the Creditanstalt, the most influential banking house in Austria, in May 1931, brought Austria close to financial and economic disaster. This, together with the rise of the National Socialists in Germany, brought considerable support to the Nazis in Austria, and the provincial elections in 1932 showed that they had now a considerable mass following. The Nationalists began to demand a general election, and this demand was taken up by the Social Democrats in their anxiety not to be associated with the Social Christian government.

3. Dollfuss and Schuschnigg.—As a result when Engelbert Dollfuss (*q.v.*) formed a Social Christian government on May 20, 1932, he could count on a majority of only one vote. Dollfuss belonged to a new generation which had been educated in the conservative conviction that the western form of parliamentarian government had been forced upon the central Europeans as a result of military defeat and socialist revolution, and that the political and social order could be restored only by the establishment of some kind of strong authority. The leaders of the Social Christian Party found themselves under attack from two ideological enemies, the Marxists and the Nazis, who apparently threatened the very basis of the conservative order. The weak position of the Social Christian government made it imperative for Dollfuss to replace the democratic government by an authoritarian one. The opportunity to do this came in March 1933 when, during the debate on a minor bill, an argument arose over alleged irregularities in the voting procedure. Renner, the president of the *Nationalrat*, resigned; the two vice-presidents followed his example and Dollfuss declared that parliament had proved unworkable. It never met again with full membership and Dollfuss governed henceforth by emergency decree.

By this time (spring 1933) Hitler was in power in Germany, and Nazi propaganda for the incorporation of Austria was vastly increased. In this situation Dollfuss turned to Italy for help, being convinced that British and French aid would be ineffective. This shift in foreign policy can also be attributed to the fact that Dollfuss had to rely on the help of the *Heimwehr* to stay in power. The anti-Marxist *Heimwehr* had been in close contact with the Italian Fascist Party for a number of years already, and when Dollfuss visited Mussolini at Riccione in August 1933 he secured Mussolini's promise to protect Austria's independence only on the condition that he would give the *Heimwehr* a free hand in the destruction of the Social Democratic Party in Austria.

The Social Democrats were subjected to increasing provocation and on Feb. 12, 1934, took to arms. Civil war followed. Though the workers operated a general strike, the armed resistance was limited to the members of the *Schutzbund*, now a small force. After four days fighting Dollfuss and the *Heimwehr* were victori-

ous. The Social Democratic Party was declared illegal and driven underground. In the course of the same year, all political parties were abolished except the *Vaterländische Front* ("Patriotic Front"), which Dollfuss had founded in 1933 to unite all conservative groups. In April the rump of the parliament was brought together and accepted an authoritarian constitution. The new constitution had its spiritual basis in the social teaching of the Roman Catholic Church as expressed in the papal encyclical *Quadragesimo anno*. The framework of organization was to be a system of occupational estates, and the executive was given complete control over the legislative branch of government. The elected assemblies disappeared and were replaced by advisory bodies, appointed in complicated and futile fashion. The rights of man guaranteed under the democratic constitution were also swept away. "Republic" was removed from the official name of the state which was now merely "the Federal State of Austria."

On July 25, 1934, a group of Nazis seized the chancellery and attempted to proclaim a Nazi government. Dollfuss, whom they had taken prisoner, was murdered. The plan, however, miscarried: the Nazi party in the chancellery was compelled to surrender, and its leaders were executed; a Nazi rising in Styria was suppressed; and, faced with the mobilization of an Italian army on the Brenner Pass, Hitler repudiated his Austrian followers. Franz von Papen was sent as German ambassador to reduce Austria by other means.

Kurt von Schuschnigg, who became chancellor on the death of Dollfuss, was a man of gentler personality and of less violent political passions. The administration of the authoritarian constitution became, in the easygoing Austrian fashion, less oppressive than its Italian and German counterparts. In a vague way Schuschnigg would have liked to restore the Habsburgs, but he shrank from the international complications that this would involve. Therefore the regime drifted on without popular favour, weakened by the personal rivalries and ambitions of its leaders and sustained only by a guarantee from Italy. The temporary accord of Great Britain, France, and Italy in the "Stresa front" (April 1935) seemed to promise new security, but the Ethiopian crisis soon destroyed the unity of the western powers, and Austria's isolation was complete when Hitler and Mussolini allied themselves in 1936. On the other hand, Hitler was not yet ready for any great stroke. Schuschnigg was therefore able to negotiate a compromise with Germany on July 11, 1936: Germany promised to respect Austrian sovereignty; in return Austria acknowledged itself "a German state." Schuschnigg promised amnesty to the Nazis and held out a prospect of including some "nationally minded" Austrian in his ministry in the future. The agreement of July 1936 did not bring any serious change but left Austria open to Nazi infiltration. The Austrian Nazis continued to conspire. In January 1938 the Austrian police discovered that a new Nazi *Putsch* was in the offing. Schuschnigg thought to defeat this conspiracy by a meeting with Hitler, where he would confront him with the evidence, but Hitler, though he had not ordered the plot, came down on the side of the conspirators. At Berchtesgaden on Feb. 12 terms of surrender were dictated to Schuschnigg. He had to agree to give a general amnesty to the Austrian Nazis, to suppress the evidence of the plot and to include some leading Nazis in his cabinet. Mussolini had by then abandoned hope or intention of protecting Austria. Nevertheless Schuschnigg resolved to challenge Hitler alone. On March 9 he announced that a plebiscite would be held on March 13 to decide in favour of Austrian independence.

4. Anschluss.—Hitler could not allow Schuschnigg's plebiscite to be held: having himself much experience with plebiscites, he knew it would go in favour of whoever was running it. Though the Austrian crisis had taken him unawares, he acted with energy and speed. Mussolini's neutrality was assured, there was a ministerial crisis in France and Neville Chamberlain in Great Britain was in the first flush of appeasement. On March 11, 1938, two peremptory demands were made for postponing the plebiscite and for the resignation of Schuschnigg. Schuschnigg gave way. German troops, accompanied by Hitler himself, entered Austria on March 12.

It seems to have been Hitler's original intention merely to establish a Nazi government in Austria, headed by Arthur Seyss-Inquart, but once on Austrian soil Hitler was intoxicated by the general enthusiasm and proclaimed the union of Austria with Germany on March 13. A plebiscite on April 10, held throughout greater Germany, recorded a vote of more than 99% in favour of Hitler.

Austria became the Ostmark (east mark) and was absorbed into Germany for all purposes. There was at first some friction between local Nazis and those brought in from the old *Reich;* but this ceased as the local Nazis were given positions elsewhere. There was, on the other hand, an Austrian movement of resistance against Hitler, but this was naturally obliged to operate in secrecy.

5. Second Republic.—Nevertheless a myth of Austrian independence persisted, and the Allies in World War II committed themselves to this at the meeting of foreign ministers in Moscow on Oct. 30, 1943. This was subsequently confirmed at the meeting at Teheran, though Winston Churchill made various proposals for a unification of Austria and Bavaria or other neighbouring countries as late as spring 1945. As a result, when the Soviet troops captured Vienna on April 13, 1945, they at once set up a government under Renner, based on a coalition of Social Democrats, Social Christians, and Communists. The Allies agreed in July on the division of Austria, including Vienna, into zones of occupation, in which the respective Allied military commanders had supreme political powers. In October 1945 the Renner government was finally recognized by all four occupation powers as an all-Austrian government. A general election held in November 1945, in which former Nazis were excluded from voting, returned 85 members of the Austrian People's Party (corresponding to the Social Christians of the prewar period), 76 Socialists (corresponding to the Social Democrats), and 4 Communists. Renner resigned and was elected president of the republic; Leopold Figl, leader of the Austrian People's Party, became chancellor, though still with a coalition ministry. The occupying powers called on the assembly to draw up a new constitution; it replied on April 13, 1946, that the constitution of 1929 should be restored. In June 1946 the control agreement of July 1945 regulating the machinery of Allied political supervision was modified by restricting Allied interference essentially to constitutional matters.

In November 1947 the only Communist minister, K. Altmann, resigned from the government in protest against the monetary reform bill. The Austrian People's Party and the Socialists were thenceforth to be for years the sole partners in a coalition government which was formed in proportion to the parties' strength in parliament. This principle of proportional representation, originally introduced into Austrian politics for election purposes in 1919, was to be the main factor of Austrian public life from 1945.

From 1945 to 1952 Austria had to struggle for survival. After liberation from the Nazi rule the country faced complete economic chaos. Aid provided by the United Nations Relief and Rehabilitation Administration (UNRRA) and, from 1948, support given by the United States under the Marshall Plan made survival possible. Heavy industry was nationalized in 1946, and by a series of wage-price agreements the government tried to control inflation. Reconstruction was especially difficult in the Soviet zone of occupation, where the military commanders continuously interfered in political and economic affairs. The result was a migration of capital and industry from Vienna and Lower Austria to the formerly purely agricultural western provinces. This brought about a far-reaching transformation of the economic structure of the country.

Austria long remained occupied by U.S., British, French, and Soviet forces. A treaty had been expected early and the western allies were anxious to conclude one, but the Soviet government frustrated them. In 1947, however, at the time of the Italian peace treaty, the British government declared that it regarded the state of war as ended. In 1953, moreover, a heavy burden was removed from the Austrian economy when the Soviet government declared that it would pay its own occupation costs (as the U.S. had done since 1947). Thereupon the British and the French followed suit.

When, in 1949, the former Nazis were allowed to participate in

the general election, the third group in Austria's prewar party life was restored. The Union of Independents (later renamed as the Freedom Party), corresponding to the former German Nationalist group but free now from ideological ties, won 16 seats in parliament. In the subsequent elections (1953, 1956, 1959) the relationship of the three parties remained stable (1959: Austrian People's Party, 79 seats; Socialists, 78; Freedom Party 8).

When Renner died (Dec. 31, 1950), Theodor Körner, the Socialist mayor of Vienna, was elected president of the republic by direct popular vote. On his death (Jan. 4, 1957) the leader of the Socialist Party, Adolf Schärf, was elected president.

The influence of the Socialists in the coalition government, which had been relatively strong under Leopold Figl's chancellorship, was reduced when the Austrian People's Party replaced Figl with Julius Raab in spring 1953 and had Reinhard Kamitz appointed minister of finances. The subsequent economic reconstruction and the advance to a prosperity unknown to Austrians since the years before World War I is generally identified with the so-called Raab-Kamitz course, based on a modified free market economy. The nationalized steel industry (VÖEST [Vereinigte österreichische Eisen und Stahlwerke] at Linz), electrical power plants (notably Kaprun in the Tauern) and oil fields (in Lower Austria), together with the privately owned lumber and textile industries and the tourist traffic, were the major economic assets.

6. Austria Free and Neutral.—The Berlin conference of the foreign ministers of the Big Four (January 1954) raised Austrian hopes for the conclusion of a peace or state treaty. There for the first time Austria was admitted as an equal conference partner, but the failure of the foreign ministers to agree on the future of Germany again prejudiced Austria's chances. It appeared that the Soviet government was not prepared to forego its strategic advantages in Austria so long as Germany was not "neutralized."

Early in 1955 the Soviet government suddenly reversed its ten-year-old Austrian policy, probably in the hope that the Austrian example would induce the Federal Republic of Germany also to follow the road of neutrality. The Soviet government was now ready to sign the Austrian state treaty and, on its entering into force, to evacuate the occupation troops.

The treaty was signed in Vienna on May 15, 1955, by the representatives of the four powers and Austria. It formally reestablished the Austrian republic in its pre-1938 frontiers as a "sovereign, independent, and democratic state," but did not include a guarantee of neutrality. It prohibited *Anschluss* or union between Austria and Germany as well as the restoration of the Habsburgs. It guaranteed the rights of the Slovene and Croatian minorities in Carinthia, Styria, and Burgenland. The United Kingdom, the United States, and France relinquished to Austria all property, rights, and interests held or claimed by or on behalf of any of them in Austria as former German assets or war booty; but the U.S.S.R., in addition to about $1,250,000,000 taken during the occupation, obtained tangible payment for the restoration of Austrian freedom. This included $150,000,000 for the confiscated former German enterprises that Austria had to buy back from the Administration of Soviet Property in Austria, together with $20,000,000 allegedly advanced to these enterprises by that administration; $2,000,000 for the confiscated German assets of the First Danube Steamshipping Company; and 10,000,000 metric tons of crude oil as the price of Austrian oil fields and refineries that had been Soviet war booty.

The state treaty came into force on July 27, 1955. By Oct. 25 all occupation forces were withdrawn and Austria recovered its full sovereignty. On Nov. 5, duly approved by both houses of the parliament, a constitutional law of perpetual Austrian neutrality was promulgated. (F. F)

In April 1961 Raab resigned and was succeeded as chancellor by a fellow member of the People's Party, Alfons Gorbach. In the election of November 1962 the People's Party won 81 seats, the Socialists 76, and the right-wing Freedom Party 8. The government coalition was patched together with difficulty, the Socialists opposing return of the archduke Otto of Habsburg, eldest son of the last emperor. In February 1964 Gorbach resigned and Josef Klaus (chairman of the People's Party) became chancellor. On the demand of the Socialists, he published a statement excluding the archduke from Austria. President Schärf, who died on Feb. 28, 1965, was succeeded by Franz Jonas.

In the seventh general election (March 6, 1966) since World War II, the People's Party took 85 seats (of 165 in the *Nationalrat*); the Socialists dropped to 74 seats, and the Freedom Party to 6. A new era in Austria's political history began on Apri. 19 when Klaus and his People's Party formed the first noncoalition government of the postwar period. In June the archduke Otto was granted a visa to return.

After recovery of national independence, Austria's principal difficulty in foreign affairs was with Italy on the old question of Alto Adige (*see* TIROL). Agitation against Italian rule by some of the Germans there, who occasionally resorted to terrorism continued in the 1960s and provoked diplomatic protests from Rome against the toleration allegedly accorded by Austria to refugee terrorists. (X.)

IV. POPULATION

The total population at the 1961 census was 7,073,807. (In 1951 it was 6,933,905.) This figure included about 350,000 former refugees, most of them naturalized. The disparity between areas, and especially the great concentration in and around Vienna is due to historical reasons as well as to the physical nature of the country. (Distribution by *Bundesländer* [states] is shown in the table.) The principal centres of population outside Vienna are Graz, Linz, Innsbruck, Salzburg, and Klagenfurt (*qq.v.*).

Of the 3,370,000 persons gainfully employed in 1961, 47% were engaged in industry and trade and 23% in agriculture and forestry; more than a reversal of the 1910 percentages of 27.5 and 33. The birth rate increased from 14.8 per 1,000 in 1951 to 18.6 per 1,000 in 1961. The death rate declined from 12.7 to 12.1 in the same period. Despite the absence of official family-planning facilities, birth rates are lowest in the larger cities; these owe their growth—or in the case of Vienna the arrest of its decline—to the

trend of urbanization; *i.e.*, migration from rural areas to towns. Thus the countryside, despite its surplus of births over deaths, has experienced a slight but steady decline in population, especially in the eastern parts of Austria that formed the Soviet zone of occupation. Also characteristic of the rural areas is a high rate of illegitimate births, generally around 25%. This is largely due to the custom whereby a farmer's son does not marry before taking possession of the farm. Another population movement that has been going on for some time has been from higher to lower altitudes, although the growth of tourism has in some valleys reversed this trend.

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—The constitution in force in the early 1960s was a slightly modified version of that of 1929 which itself incorporated certain amendments, principally in a centralist direction, of the original constitution that had established Austria as a democratic republic and a federal state in 1920. There is a sharp separation between legislative, executive, and judiciary powers, and adequate guarantees of human rights and liberties are included, many of them originating in laws dating as far back as 1862 and 1867. The constitution also embodies a section of the Treaty of St. Germain (1919) guaranteeing the rights of minorities. It may be summed up as a parliamentary-presidential type of federal constitution with a strong bias toward centralism.

The federal nature of the state is expressed both in the division of administrative powers between the central government and the *Bundesländer*, and in the composition of the central legislative body. A fairly comprehensive list of powers is allocated to the central government for both legislation and administration. There is a further mixed sphere of government where the centre legislates, either in detail or in principle, and the *Bundesländer* carry out the administration. All further residual powers remain with the *Bundesländer*.

The legislature consists of a lower house (*Nationalrat*) elected directly by the nation on the basis of equal, direct, secret, and personal suffrage of all persons over the age of 20, under a modified system of proportional representation, and an upper house (*Bundesrat*) drawn from representatives of the *Bundesländer*, whose influence on national legislation is restricted to the exercise of a suspensory veto. Each *Bundesland* has its own assembly (*Landtag*) and elected governor (*Landeshauptmann*), the latter acting in a dual capacity as chief provincial official for the central administration and premier for the *Bundesland*. An independent constitutional court acts as guardian over the constitutional rights of the citizen and mediates in constitutional disputes between the *Bundesländer* and the central government, and a similar administrative court deals with violations of administrative powers.

2. Political Parties.—The second republic is characterized by the small number of parties and the dominance of the two main parties, the Austrian People's Party (Ö.V.P.) and the Austrian Socialist Party (S.P.Ö.) which since 1945 have formed coalition governments. The People's Party in all general elections gained the majority of seats in parliament and provided the chancellor. It is progressively conservative and believes in free enterprise, although it has carried through measures of nationalization. Its largest following is among farmers, the middle classes, and active Roman Catholics of the intelligentsia. It enjoys the unofficial support of the church and is colloquially referred to as "the black party" (from the priests' cassocks). The Socialist Party would like to see the economy nationalized in all its branches, but it stands much nearer the centre than its predecessor the Social Democratic Party, though still popularly known as the "red party." Its principal following is in the industrial areas, especially Vienna, where since 1918 all elected mayors have been Socialists. In all presidential elections after 1945 they gained the majority. The Austrian Communist Party (K.P.Ö.) gained its maximum of five seats in 1949, but lost its three remaining seats in 1959. The other party of any significance, and since 1959 the only opposition party in parliament, is the Austrian Freedom Party (F.P.Ö.). It was started in 1949 as the Union of Independents, and tends to the right wing; its backing (16 seats in 1949; 8 in 1959) comes mainly from former "nationalists" and also from liberals. The composition of the *Nationalrat* after the election of 1962 was: Ö.V.P., 81 seats; S.P.Ö., 76 seats; F.P.Ö., 8 seats.

3. Taxation.—Austrians are among the most heavily taxed people in Europe. In the early 1960s national taxes amounted to over one-fifth of the gross national product, and local taxes and national insurance contributions tended to raise the proportion. National taxation includes: (1) income tax, payable by all individuals on the amount by which the joint household income exceeds 9,500 schillings a year, subject to the graded tax-free allowance and allowances for dependents; standard rate varies according to the level of income up to an absolute maximum of 52% of total income for an unmarried person under 40, and allowances are similarly graded. (2) Corporation tax, paid by companies and other legal persons in lieu of income tax and assessed on total profits before payment of dividends. (3) Turnover tax, payable on all sales and services except exports, public utilities, public undertakings, and postal services, which is of the "cascade" type levied at each transfer of ownership. (4) Transport tax levied on the gross receipts for conveyance of persons or commodities. (5) Equalization of burdens tax, at 18% of income or corporation tax, which is a kind of surtax designed to even out family burdens and promote housing. (6) Property tax assessed at 0.5% of the value of all assets owned inside and outside Austria, subject to an allowance for Austrian residents against the first 40,000 schillings. (7) Acquisition of rights tax payable on share issues and contribution of capital to a partnership or by a foreign company to an Austrian branch. (8) Estate transfer tax payable on purchase or acquisition of real estate. (9) Insurance tax on insurance premiums. Indirect taxation affects goods such as tobacco, beer, wines, spirits, and petroleum products, and there are taxes on motor vehicles, casinos, and lotteries, stamp taxes on bills, petitions, etc., and customs duties. Local taxes include those on industry and trade and on real estate, though nearly one-third of the latter goes to the federal authorities, and taxes for fire protection, housing construction, etc. Taxes for specific purposes may be levied nationally or locally. The two principal religious denominations are legally entitled to collect from their members a tax assessed on income.

4. Employment.—Recovery after World War II was substantial. Full employment was achieved by 1960 and real wages on an average were about 45% higher than in the immediate prewar years, and in no case had they lagged behind increases in the cost of living. There is no state control of wages (except for a statutory minimum), which are fixed by collective bargaining, agreements being legally binding for all employees, both union and nonunion. Wages were improved by holidays and bonuses. Many classes of salaried employees received a double monthly salary twice yearly.

The rights of employees are safeguarded by a closely knit system of laws and regulations. They can receive free advice and representation from the Chamber of Workers and Employees of the *Bundesland*. In every factory with more than five employees a workers' delegate, and in one with more than 20 employees

Austria: Population Distribution, 1961 Census

Bundesländer	Area sq.mi.	Area sq.km.	Population	Density per sq.mi.	Density per sq km.	Capital or administrative seat
Vienna (Wien)	160	414	1,627,566	10,172	3,931	
Lower Austria (Niederösterreich)	7,402	19,170	1,374,012	186	72	Vienna
Styria (Steiermark)	6,326	16,304	1,137,865	180	70	Graz
Upper Austria (Oberösterreich)	4,625	11,978	1,131,623	245	94	Linz
Carinthia (Kärnten)	3,681	9,534	495,226	135	52	Klagenfurt
Tirol	4,883	12,647	462,899	95	37	Innsbruck

a works council, must be elected by secret ballot. The 16 unions of the Austrian Federation of Trade Unions are not linked to any political party. By the early 1960s trade union membership, which is not compulsory, was about 1,500,000 or about two-thirds of all employed.

5. Housing and Welfare.—In the early 1960s rents were low, on average 5.2% of income of a working class family. There was an almost absolute rent control by the state except for nonsubsidized houses built privately after World War II. Few improvements could be made by landlords of older property.

The first laws regulating sickness and accident insurance were passed toward the end of the 19th century, and under the first republic a ministry of social welfare was established. A new beginning was made in 1945, and the basis of the present system is the General Social Insurance act of Jan. 1, 1956. All employees and most self-employed are obliged to belong to a comprehensive social insurance plan. In the early 1960s there were about 300 hospitals and nursing homes and the over-all ratio of doctors and dentists to inhabitants was 1 for 560, the lowest in Europe. Other public expenditure for welfare purposes included child allowances to wage earners and salaried employees, school meals and holidays for children, special training of physically handicapped persons, and scholarships for university students.

6. Justice.—According to the constitution justice is a federal matter. All courts (except those of arbitration) are state courts and all judges are appointed by the federal president or on his behalf by the minister of justice. Once appointed, judges have complete independence and can neither be dismissed nor transferred. They give judgment according to the law but have the right to interpret it according to the circumstances. In addition to the professional judges there are also *Schöffen* ("lay magistrates"), who in certain cases sit on the bench with professional judges. Juries are only called upon for the most serious crimes. In case of conviction they determine the sentence jointly with the judges.

The lowest courts are the 231 *Bezirksgerichte* ("district courts"), which are only competent to deal with minor misdemeanours and minor civil cases. Linked with these courts administratively but not functionally are the *Arbeitsgerichte* ("industrial courts"). The next higher level consists of the 20 provincial courts, *Kreis- und Landesgerichte*. These, besides being courts of appeal against judgments of the lower courts, may try all civil cases and criminal cases liable to penal servitude of up to the limit of ten years. More serious cases, which include political crimes such as high treason, are tried by a *Geschworenengericht* ("jury") of three judges and eight jurors. The *Oberlandesgerichte* ("high courts") at Vienna, Graz, Linz, and Innsbruck, presided over by three professional judges, are courts of appeal in criminal and civil cases. The *Oberster Gerichtshof* ("supreme court") of five judges is the final court of review in civil cases and court of appeal in criminal cases. It is also the final appeal court for cases previously heard before the *Handelsgericht* ("commercial court") or the *Jugendgericht* ("juvenile court"), both at Vienna. The *Verfassungsgericht* ("constitutional court"), also at Vienna, is responsible for cases involving interpretation of the constitution. The police are empowered to collect fines on the spot for certain minor offenses (especially traffic offenses). The accused, however, has the right of trial by a regular court.

The basis of the civil law is the general civil code of 1812 with additions, including those after World War II. The criminal code, dating from 1852 and since frequently amended, imposes sentences of fine, imprisonment, penal servitude, and loss of civil rights. Corporal punishment was abolished in 1867 and capital punishment (except under martial law) first in 1919 and, after reintroduction in the early 1930s, again in 1950. Commercial law is largely based on the German commercial code of 1897; additions were made after 1950. Industrial law includes clauses applicable to all types of employment (*e.g.*, the protection of children and juveniles and employee representations) and to various groups of employees. Normally the only permissible language at court is German, but exceptions are made for Austrian citizens of a different mother tongue. Court cases, even while still *sub judice*, may be the subject of free comment in the press.

7. Education.—The standard of education in Austria is high, and the modern methods of teaching associated with the reforms of Otto Glöckel (1874–1935) in the 1920s won general recognition abroad. A new education act was introduced in 1962 concerned with reorganization in secondary schools. Compulsory school attendance between the ages of 6 and 14 was introduced in 1869. The basic school is the eight-year elementary school (*Volksschule*) but there is in most of the larger places a four-year advanced school (*Hauptschule*) which replaces the last four years of the elementary school and provides a somewhat higher level of general education. In the early 1960s there were more than 4,500 elementary schools (with about 570,000 pupils) and 866 public advanced schools (with 187,000 pupils). Education in the first four years of the *Volksschule* is universal, after which the pupil may continue either in the *Volksschule* or the *Hauptschule*, or upon passing an entrance examination may attend a secondary school from the age of 10 to 19. The secondary schools, which numbered about 200 with an attendance of 82,000, are of three main types: the classical *Gymnasium*, teaching Latin and Greek and one modern language; the *Realgymnasium*, teaching Latin and two modern languages; and the *Realschule*, which emphasizes mathematics and science, with two modern languages. Obtaining the leaving certificate confers the constitutional right to a place at an institution of higher education. In addition to the secondary schools there are various vocational, technical, commercial, and agricultural schools, which the pupil may enter at the age of 14; there are also about 30 teacher training colleges with about 8,000 students. Adult education of every type is also highly developed, particularly in Vienna, where it is largely associated with the Socialist Party. Austria has four universities—at Vienna, Graz, Innsbruck, and Salzburg. The last, refounded in 1963, offers only a limited range of subjects. There are also nine colleges of university rank and academies of fine arts and music. The total number of students exceeded 50,000 in 1964.

8. Defense.—The state treaty of May 15, 1955, authorized Austria to restore its national armed forces and fixed no limitation of their size. However, the treaty prohibited the service in the Austrian armed forces (1) of persons not of Austrian nationality (2) of Austrian nationals who had been German nationals before March 13, 1938; (3) of Austrian nationals who served with the rank of colonel or higher in the German armed forces between March 13, 1938 and May 8, 1945; and (4) of Austrian nationals who had been members of the National Socialist (Nazi) Party or its subsidiary organizations, except those who were exonerated by the appropriate body in accordance with Austrian law.

On Sept. 7, 1955, a defense act establishing Austrian armed forces was promulgated. It introduced compulsory military service for all fit males between the ages of 18 and 51. The peacetime army consists of recruits serving nine months, of volunteers for longer service and of professional officers. Special technical units are recruited from volunteers serving 15 months. In 1960 the Austrian forces consisted of 245 units with about 50,000 men. The supreme command is vested in the federal president. The *Militärakademie* (officers' training school) at Wiener Neustadt, originally founded in 1752, was reopened on Dec. 14, 1958. In September 1961 it was decided to set up an organized militia of 20–25 units for frontier guard service in the border zone.

VI. THE ECONOMY

When the new Austrian republic came into being in 1918, it was economically unbalanced. Cut off by customs barriers from the areas which had supplied coal and much of its food, and which had been its major markets, it seemed to have little chance of survival. In the early years of the republic, banks and many other enterprises failed, inflation set in and there was widespread unemployment.

Recovery did not begin until the mid-1920s and was largely initiated by international loans (see *Finance* below). Much progress was made during the next few years toward an adjustment to the new conditions which necessitated the development of water-power resources, agriculture, and manufacturing industries. The developing tourist trade and earnings from international transit

traffic also helped toward stabilization. This stage came to an abrupt halt after the world economic crisis of 1929, and the resulting unemployment and decline of living standards gave rise to a political restlessness which led to civil unrest. Politics dominated Austria's economy until the *Anschluss* with Germany in March 1938. Thenceforward Austria's economy became geared to the requirements of German rearmament and war. This resulted in expansion and modernization in all heavy industries, the establishment of large plants, like the iron and steel works at Linz, erection of industrial plants in some Alpine valleys for strategic reasons, the building of hydroelectric power stations, and a great increase in the exploitation of the oil fields northeast of Vienna where production rose from under 33,000 tons in 1937 to almost 1,250,000 tons in 1944.

After World War II Austria once more became a separate state, and again faced vast economic problems. There had been considerable damage to housing, industries, and communications, and in the Soviet occupation zone there was much interference with the economic life. The basis for this was a clause in the Potsdam Agreement of August 1945 which gave each occupation power title to the German assets in its zone. While the western Allies transferred their German assets in 1946 to the trusteeship of the Austrian government and in 1949 relinquished their claims altogether, the Soviet authorities took over every enterprise which they considered had been under German control. These numbered about 250, the largest being part of the First Danube Steamshipping company and the entire oil industry. After initially removing machinery and equipment, they changed their policy and appointed an Administration of Soviet Property in Austria (USIA) which had also its own retail organization. Thus until the conclusion of the state treaty in 1955, when Austria agreed to buy these enterprises back in cash and goods to the total value of $332,000,000 (£110,-650,000), this large section of Austrian industry was exploited without reference to the requirements of Austrian economy.

Although the annexation by Germany was the cause of these difficulties, Austria economically experienced a net gain, notably in iron and steel, nitrogenous fertilizer and aluminum industries, staple fibre manufacture, hydroelectric power stations, and communications. The *Anschluss* period had also increased the industrialization of the western *Bundesländer* and thus evened out the unequal distribution of industry of the time before 1938.

As after World War I, the economic recovery of Austria after World War II was largely made possible by foreign aid. Until late 1947 even a bare survival would have been impossible without this aid, given largely by UNRRA, the United States, the United Kingdom, and private bodies (the value of goods received was approximately $500,000,000 or more than £165,000,000). Similarly, the long-term reconstruction plan was only made possible by the inclusion of Austria in the European Recovery Program (Marshall Plan aid), under which it received altogether $962,000,000 (£320,-650,000). Of this, the bulk was used for investment in the following (in order of magnitude): industry, hydroelectric power plants, agriculture and forestry, and public communications. Internal measures contributing to the success of the recovery program included currency reforms and price and wage agreements. In 1954 the budget was balanced for the first time, and the financial year closed with a surplus of 500,000,000 schillings (about $19,600,000). Progress continued into the 1960s. In May 1960 Austria formally became a member of the European Free Trade Association. Since, however, more than 50% of her exports go to the Common Market she applied in 1964 for associate membership of the EEC.

A. Production

1. Agriculture.—Because of its mountainous character barely half of the surface is suitable for agricultural use, more than one-third is under forest, and about 13% is unproductive. Although mixed farming prevails there is a principal subdivision of live-stock or arable farms, but statistics distinguish nine different types of farm, depending on the different proportions of land use. For instance, three different types of wine-producing farms are noted, devoting a varying proportion of their land to the production of wine; such are frequently found in the *Weinviertel* ("wine quarter") of Lower Austria, the Neusiedler Lake region, and southeastern Styria. The total area under vineyards is about 98,850 ac. (40,000 ha.) and in 1961 production was approximately 1,195,000 hl. (about 26,300,000 imperial gallons).

Fruit cultivation is widespread but subsidiary to other farming. Apples take first place, especially in Styria. In Upper and Lower Austria much of the apple crop is made into *Most* ("cider"), largely for farm consumption. Two-thirds of the pear harvest also is of cider quality. Stone fruits (plums, apricots, and peaches) are also grown. Walnuts are grown chiefly in the Burgenland.

Of the agricultural land (9,416,000 ac. or 3,851,000 ha. in 1960), arable accounts for about 40%, followed by meadows and pastures, and alpine grassland with approximately 38% and 22% respectively. The bulk of arable land is in the Alpine foreland and the Eastern lowland; these regions account between them for more than 90% of the total, 40% being in Lower Austria. Most of the meadows and pastures are in the southern part of the Alpine foreland and the Flysch zone, the Granite plateau, and the lower Mur Basin in Upper Austria, Styria, and Lower Austria. More than one-third of the alpine grassland is in the western Central Alps.

Grain, which takes half of the plowland, is the most important crop. In the early 1950s rye was overtaken by wheat, a reflection of changing consumption habits. Various measures have resulted in increased yields per hectare and since 1961/62 self-sufficiency in bread. While self-sufficiency in potatoes was maintained it dropped in sugar to around four-fifths. In the mountainous areas, where most farm land is for hay and grazing, cattle are the mainstay of the economy; during the summer months most of them graze on the mountain pastures, a practice which makes for a healthy stock besides bringing the high areas into use. The number of horses has declined though horse breeding in the Alpine area remains important. The raising of goats and sheep, which in the Alps use the poorest and highest pastures, is insignificant.

The Alpine areas cannot compete in stock numbers with the arable areas of the Alpine foreland and the Eastern lowland, where fodder crops occupy much of the farm land. As in arable farming, there has been a steady improvement in stockbreeding, reflected by the increase of milk yields. Difficulties are that the principal breeds are not specifically dairy cattle, and that on small farms about one-quarter of Austria's cows are used also as draft animals. However, the country did become self-supporting in dairy products after 1956. Most farms have a few pigs which have increased in quality through improved breeding methods. Hens are raised everywhere.

To be fully competitive within a free European market, a great deal more has still to be done. Since 1961 a "green plan" has been in operation to improve the agricultural structure. The most urgent task is reallocation of farm land of which in the 1960s more than 2,500,000 ac. (approximately 1,000,000 ha.) still needed attention. Equally serious is the prevalence of small farms: 23% of the total of about 400,000 farms and holdings are under 5 ac. (2 ha.) and another 24% under 12½ ac. (5 ha.). About 90% of Austrian farmers own all or most of the land they farm and only 5% of holdings are pure tenant farms.

2. Forestry.—Forests cover more than 7,500,000 ac. (3,000,-000 ha.), about 37% of Austria's surface. In percentage of the productive area Austria takes fourth place among European states. The forests yield approximately 9% of the national income and in the early 1960s timber, timber products, and paper accounted for almost one-fifth of the total exports.

Conifers, mainly spruce, form about 84% of the forest area; the rest is deciduous in which beech predominates. Here, as in farming, the major handicap to efficiency is the property structure, as a result of which more than half of the total forest area is privately owned and consists of lots smaller than 123½ ac. (50 ha.). Lack of capital and training makes for inefficiency and about one-quarter of the total yield is consumed by the producers. State forests (15% of the total) and large private forests are the best kept. Owners of the small forests are encouraged to combine into forest utilization co-operatives. Overcutting took place during and after World War II, and the state has subsidized reforesta-

tion schemes and the building of access roads.

3. Mining.—Mining of salt, copper, and iron in Austria is of prehistoric standing and attracted people into areas otherwise hostile to settlement, like the Hallstatt region, where the wealth of the salt mines made it an important cultural centre, giving its name to the Early Iron Age period. The mining of these products continued during the Middle Ages and gold, silver, and precious stones in the Central Alps, and lead in Carinthia were also won. By mid-20th century the mining of precious metals had ceased, but other minerals such as coal, magnesite, kaolin, petroleum, and natural gas were extracted. By the early 1960s the total number of employees in the extractive industries averaged 30,000, nearly half in coal mining. While hard coal resources are small, the only economical mines being at Grünbach in Lower Austria, there are many brown-coal fields. The total coal reserves are estimated at 300,000,000 tons and production has much increased since 1937. There are, however, marketing difficulties, and competition from imported coal or oil. Calculated on the basis of the calorific value of hard coal, home coal production can satisfy only about one-third of Austria's needs.

Oil was discovered in 1932 near Zistersdorf, north of Vienna. Production rose slowly until 1937 (33,000 metric tons), and reached a peak of nearly 3,700,000 tons in 1955, after which it declined by more than 1,000,000 tons. Associated with oil is the production of natural gas, which increased from 285,000 cu.m. (1 cu.m = 35.314 cu.ft.) in 1937 to 1,699,000,000 cu.m. in 1963, making Austria third producer in western Europe after Italy and France. Proved reserves were estimated at 58,500,000 tons of oil and 30,000,000,000 cu.m. of gas. A modern oil refinery at Schwechat (Vienna) began operating in 1960. Home production satisfied 60% of needs in the early 1960s.

Iron ore is the most important metal. About three-quarters of it comes from the Erzberg in Styria where it is quarried rather than mined and production costs are low. It is also mined at Hüttenberg in Carinthia. Although annual production normally exceeds 3,700,000 tons (iron content about 1,200,000 tons), this is insufficient and a considerable amount of ore, pig iron, and scrap has to be imported. The total reserves are estimated at 330,000,000 tons. Next in importance are lead-zinc-molybdenum and copper ores. The former occur in Triassic rocks at a number of places in the southern Limestone Alps and mining is centred in Bleiberg ob Villach. Annual production exceeds 190,000 tons; the lead from these ores amounts to about 5,000 tons or half the requirements and the zinc is of similar tonnage. Copper ore occurs in the northern Shale Alps but the copper content is low (2.2%) and only the largest deposits near Bischofshofen (Salzburg) and near Schwaz (Tirol) are used. (At the latter place the ore contains small amounts of mercury and silver.) Annual production averages 140,000 tons. The copper smelting is done at Brixlegg (Tirol); production averages 10,000 tons, of which about one-fifth comes from home produced ores.

The mining of magnesite, for which Austria once possessed a world monopoly, is important to the Austrian economy. Deposits occur in the Central Alps and the Shale Alps. The most valuable mines are at Radenthein (Carinthia), Veitsch, and Breitenau in Styria. Annual production, which exceeded 1,500,000 tons in 1960, has since declined. Raw magnesite and magnesite products are exported.

Important saline deposits occur in the lowest Triassic strata in the northern Limestone Alps. The salt is generally mixed with clay so that most is extracted by filling underground cavities with water and subsequently pumping out and evaporating the brine. The total production of salt in the early 1960s was about 170,000 tons. Brine is also used in the chemical industry and for medicinal purposes at the spas. Salt has been a state monopoly since the Middle Ages.

Other minerals mined include: antimonial ore, bauxite, graphite (much increased in the 1960s by use in iron ore smelting), gypsum and anhydrite, manganese ore, oil shales, quartz and quartz sand, talcum, and wolframite ore. A great deal of stone is quarried, mostly for public buildings.

4. Power.—Relief and climate combine to give Austria a water-power potential of about 5,000,000 kw., the greatest in central Europe. The largest hydroelectric power stations utilize the Danube. Total annual production by 1963 reached 18,444,000,000 kw-hr. (*c.* 85% hydroelectric). Most of the thermoelectric stations use Austrian brown coal except those at Vienna and Linz where Austrian oil and natural gas provide much of the fuel.

5. Industries and Crafts.—Trades and crafts occupy a leading position and form the most numerous occupation group. Apprenticeships of three to four years assure high quality and competition with industry. Most of the trades supply internal consumption, but those that produce for export contribute between them about 15% in value of Austrian exports—these are bone china, ceramics, high-quality glass goods, glass costume jewelry, petit point work from Vienna, lacework, and wood carvings.

Manufacturing industries, which employ nearly as many people as the crafts, range from heavy industries to optical or radio manufacture. In Austria the tendency is toward a large number of small specialized industries. By two acts in 1946 and 1947 a high proportion of industries were nationalized. This was in part due to complications arising from formerly German-owned plants. The controlling body for these industries, which include petroleum, coal, electricity, metal ore mining, iron and steel, and part of the chemical, electrical, machine, and vehicle industries, is a holding company set up in 1956, the Österreichische Industrie und Bergbau-Verwaltungsgesellschaft (Austrian Board of Industry and Mining). Heavy iron and steel industry is concentrated in two places: an old centre in Styria near the iron ore deposits and a newer one at Linz. Annual pig iron production, 390,000 tons in 1937, exceeded 2,000,000 tons in 1963, and production of crude steel increased from 650,000 tons to nearly 3,000,000 tons, in spite of the lack of coking coal. An important Austrian contribution to metallurgy was the development of the LD (Linz-Donawitz) oxygen converter process. Production of aluminum, the greater part for export, rose from 4,400 tons in 1937 to more than 90,000 tons in the early 1960s.

Austria's extensive timber resources have created an important paper industry, including wood pulp, cellulose, and cardboard, with 80 paper mills in the major valleys on the margins of the northern Limestone Alps and the Vienna and Klagenfurt basins. By 1963 annual production of paper exceeded 520,000 tons; more than half was exported, and was a leading foreign currency earner. The textile industry greatly expanded after World War II and synthetic fibre, yarn, cloth, and clothing made a valuable contribution to exports. Because of postwar difficulties (*e.g.*, reduction of livestock, shortage of foreign currency for import of tanning materials and leather) the leather industry was slow to recover.

The chemical industry occupies third place by value of production. Many basic chemicals are produced, especially nitrogen fertilizer, and there are rubber and plastic industries. The machine and vehicle industries are mainly concentrated at and near Vienna, Graz, and Linz; an isolated centre is at Steyr. They produce heavy machinery for metal works and rolling mills, drilling and mining equipment, agricultural machinery, lathes, pumps, looms, and many other items. There is shipbuilding near Vienna and at Linz, and locomotive and rolling stock construction at Vienna and Graz. The motor industry ranges from production of autocycles to trucks and buses, but after a peak in the late 1950s production declined in all branches.

The tobacco industry is a state monopoly. Imports come largely from Greece and the United States. Annual excise duty paid on tobacco amounts to more than 2,000,000,000 schillings, nearly one-tenth of all indirect taxes collected.

B. Trade and Finance

1. Foreign Trade.—Imports in the immediate post-World War II years consisted largely of foreign relief consignments which in 1945–46 amounted to 88% of the total. As the Austrian economy recovered these fell off and by 1954 were as low as 3[illegible] of imports.

Foodstuffs accounted for more than one-third of imports in 1937 but by the early 1960s they had dropped to about one-eighth. Machines and vehicles were the chief articles imported. Exports, in order of value, were finished and semifinished goods, raw mate-

rials, including electrical energy, and foodstuffs. The value of imports always exceeded that of exports, but earnings from services (freight charges, tourism) more than filled this gap. By 1953, for the first time in the history of the republic, Austria had a surplus (more than $70,000,000 or £25,000,000) in its balance of payments.

Since the 1950s the Federal Republic of Germany has become Austria's principal trade partner. Of exports in 1963, 49.1% went to EEC and only 15% to EFTA states, while east European countries took 18.4% and overseas countries 13.3%. Entrepôt trade is carried on at the three customs-free zones at Linz, Graz, and Innsbruck, established after World War II.

Tourist Trade.—Spas of international repute like Badgastein (*see* GASTEIN) and Baden, cities like Vienna, Salzburg (with its music festivals), and Innsbruck (*qq.v.*), the lakes of the Salzkammergut and the Austrian Alps have for long attracted tourists. This trade first reached its peak during the 1930s when most of the foreign visitors came from Germany and southeastern Europe. After World War II its recovery was slow and it was not until the mid-1950s that it became reestablished as a significant industry.

2. Finance.—After the collapse of Austria-Hungary, Austria experienced several years of inflation and financial chaos, ending only when financial help came from abroad, in particular the International Reconstruction loan of 1923, floated under the auspices of the League of Nations. From 1924 until 1930 current revenue covered current expenditure and at least a large part of state investments. In 1931, however, the world depression precipitated a financial crisis; the League of Nations was again called in to assist, and a further international loan was raised.

After World War II the Austrian government encountered serious problems. While production was at a very low level, there was a large volume of currency in circulation. Heavy budgetary expenditure was necessary both for normal purposes and for the support of the occupying forces and displaced persons, and the collection of revenue was difficult because of the disorganization of the fiscal apparatus and the division of the country into zones of occupation between which communication was at first restricted.

From 1946 onward there was a surplus on the ordinary budget, but total state expenditure was greatly in excess of revenue. This was due partly to heavy investment expenditure in the extraordinary budget, but also to extrabudgetary expenditure on occupation costs (which were optimistically regarded as a temporary item and financed by inflationary borrowing) and subsidies (which were partly paid out of funds accumulated from the sale of goods supplied to Austria for relief and rehabilitation). The over-all position was therefore inflationary. The first attempts to deal with the situation were the wage and price agreements of August 1947 and September 1948, the general aim of which was to reduce subsidies and offset the consequent price increases by wage increases, but from the state's point of view the saving on subsidies was largely cancelled out by the extra payments for wages, social welfare, etc. An acute budgetary crisis arose in May 1949, when it became clear that the original budget was quite unrealistic. A revised version was produced which increased tax rates, imposed a special tax to cover occupation costs and reduced certain subsidies; and a third wage and price agreement partially alleviated the extra burden thus imposed on wage earners. In September 1950 a fourth wage and price agreement further cut subsidies and gave consequential wage increases.

Further steps to deal with inflation were taken after 1951; credit was restricted and the bank rate was raised from 3.5% to 5% and later to 6%. These measures, together with a voluntary "standstill agreement" on prices and wages in the autumn of 1951, served to stabilize the financial situation to some extent during the following year. There was a surplus in the balance of payments in 1953, and the position had improved to such an extent that investment and social expenditure was increased in 1954, while at the same time income tax and the tax on business capital were reduced. The bank rate was reduced to 4½% in 1959.

The basic unit of the Austrian currency is the schilling, divided into 100 groschen. The schilling was first introduced in Austria in 1924 when it replaced the Austro-Hungarian krone (crown). This currency collapsed after 1918 and the schilling was at first equal to 10,000 kronen. In March 1938, after the *Anschluss*, it was replaced by the reichsmark at the rate of 1 reichsmark to 1.5 schillings. When the schilling was reintroduced after World War II a limit of 150 reichsmarks per person were exchanged on a 1 to 1 basis, additional money was valueless and banking accounts were blocked (subject to certain exceptions). Since these measures proved insufficient to prevent inflation, the currency protection bill of December 1947 provided for the issue of schillings at a rate of 1 new schilling to 3 old. From October 1946 the official exchange rate was 10.14 schillings to 1 U.S. dollar. On May 4, 1953, the schilling was devalued to 26.00 to 1 U.S. dollar.

C. Transport and Communications

The pattern of communications has been dominated by Austria's central location in Europe, in particular its position between the Mediterranean, the North, and Baltic seas, and across the Danube gap between the central uplands of middle Europe, the Carpathians, and the Alps. Early routeways which crossed the territory of present Austria were the amber road from the Baltic to the Adriatic and the salt road from the Salzkammergut into Bohemia. While the Roman Empire extended as far north as the Danube, roads across the Brenner and other Alpine passes and others following the valleys of the major rivers gained importance, which increased during the later Middle Ages and, with the formation of the Austro-Hungarian Empire, Vienna became the hub of the communication lines. Despite the breakup of the empire in 1918, Vienna retained much of its former role during the interwar period, but the division of Europe into west and east that followed World War II had a much more pronounced effect and resulted in considerable reorientation of the transit traffic, emphasizing the north-south at the expense of west-east lines.

1. Roads.—Only the federal roads, including motorways, are of international importance. The Salzburg-Vienna, Brenner Pass, and Vienna-Semmering motorways were under construction in the 1960s. Peculiarities of the Austrian road system are that the principal (No. 1) road from Bregenz to Vienna is in two sections separated from each other by German territory, that the alpine crossing at Badgastein is facilitated by taking road vehicles through the Tauern Tunnel by train, and that a similar service exists through the Arlberg Tunnel during the winter and has to be used during temporary snow blockages of the Arlberg Pass. The Grossglockner Road, which goes up to nearly 10,000 ft. and is a toll road, largely serves tourist traffic and is only open during the summer and early autumn. Licensing laws restrict competition by regular private bus services on routes served by the railways. Bus lines, largely operated by the Federal Railways and Postal Administration, provide regular services to outlying places.

2. Railways.—The earliest railways were built to link the major population centres of the Austro-Hungarian Empire. The first line ran from Prague and Cracow to Vienna and on to Graz and the then Austrian port Trieste. The first sections of this line were opened in 1839 and the stretch across the Semmering (1854) was the first alpine railway. A second tunnel under the Semmering was opened in March 1952. The main line of Austria, the Westbahn, from Vienna to Lake Constance, was not completed until 1885 with the construction of the Arlberg Tunnel. The last major railway construction was the Tauernbahn (1900), the fourth line on Austrian territory to cross the Alps from north to south. The state-owned Austrian Federal Railways (Österreichische Bundesbahnen) operate about 90% of the railway routes in Austria. Private railway construction began about 1880 and was restricted to branch lines often built in narrow gauge.

Electrification.—The end of World War I brought changes and difficulties to the Austrian railways; a number of junctions around the borders were lost and the traffic pattern changed radically. These difficulties were added to the permanent problem of the relief, with its inclined and curved sections increasing the running costs. The loss of the coalfields, the greater efficiency of electric locomotives for climbing, and the hydroelectric power potential of the country were stimuli toward electrification, which was decided on by parliament in 1920. The section Innsbruck-Landeck was

completed in 1923 and by 1938 most of the lines of the western *Bundesländer*, Vorarlberg, Tirol, and Salzburg had been electrified. By 1952 the entire Westbahn had been electrified.

Mountain and Cable Railways.—These types of "railway" are of great importance for the Austrian tourist trade. The first mountain railway operated by cogwheels was opened in 1893 (Schafberg, Salzkammergut). The first funicular cable line (*Seilschwebebahn*) for passengers began operation in 1927 to the Rax (Lower Austria). The highest, the Vallugabahn near Sankt Anton am Arlberg, goes up to 9,220 ft. Many chair lifts, operating in summer and winter, and ski tows have also been built.

3. Shipping.—Shipping in Austria is found on the larger lakes where it serves local transport and the tourist trade but commercially by far the most important is the Danube shipping. The First Danube Steamshipping Company (E.D.D.S.G.), now a state enterprise, began operating in 1830. The main commodities transported on the upstream traffic were grain, pulses, eggs, and mineral oil, and downstream timber, iron and metal goods, building material, and paper. After World War II, because of Soviet occupation of eastern Austria, shipping (except that operated by the Soviets) was at first confined to the section from Linz upstream. The U.S.S.R. had furthermore seized all ships and installations of the E.D.D.S.G. as German assets, since during the *Anschluss* it had passed to the German government. In the state treaty of 1955 Austria agreed to buy back all the assets for $2,000,000 (£714,000) and the company was by August 1955 again in Austrian hands.

By 1960 the total annual goods traffic on the Austrian section of the Danube was about 5,500,000 tons. Of the imported goods about 50% were coal and coke (mostly coming from or via Germany), 15% mineral oil and 15% iron ore. Exports included crude oil and gas oil (over 50%, three-quarters of which went to eastern bloc countries and included Austrian compensatory deliveries to the U.S.S.R.), iron and steel (23%) and fertilizers (11%). The leading Danube ports in Austria are Linz (with a customs-free zone) and Vienna. Austria was admitted to full membership of the Danube Commission, established under Soviet control in 1948.

4. Civil Aviation.—Vienna developed during the interwar years as an important junction of European air routes. Immediately after World War II, aviation was forbidden to Austria. With the signing of the state treaty Austria regained its air sovereignty and Austrian Airlines (AUA) was founded toward the end of 1957. It began operations on April 1, 1958, and in 1960, operating with Super Viscounts, covered a network connecting 22 cities in 16 countries. This service was made possible by pooling agreements with British European Airways, Deutsche Lufthansa, Swissair, and Aeroflot. The most important airport is at Vienna (Schwechat). The other commercial airports of Austria in order of importance are Innsbruck, Klagenfurt, Salzburg, Linz (Hörsching), and Graz. Austria has developed an air mountain rescue service and there are a number of glider and sailplane schools.

5. Postal Service and Telecommunications.—The Austrian postal service is the heir of the Austrian imperial mail which was established in the early 16th century as one of the first postal institutions. The telegraph service in Austria showed recessive tendencies in the early 1960s, while the teleprinter service, in which Austria possesses a dense network, was expanding. Direct-dial telephone services were introduced. All telecommunications, including radio and television, come under the jurisdiction of the postal authorities. The Österreichischer Rundfunk G.m.b.H. operates 17 television and about 100 radio stations. Television in Austria began experimentally in 1955 and regular programming started in 1957. Austria is linked with the Eurovision network.

AUSTRIA, EMPIRE OF. The connotation of the name Austria has varied with the phases in the political relationships of various territories under the Babenberg and Habsburg dynasties and has found its final expression in the Austrian republic (see AUSTRIA). The Bavarian settlements in the region now known as Lower Austria were the nucleus, and were first recorded under the designation Ostarichi ("eastern region") in the year 996. This name would seem to have been already current during the Carolingian period, whereas the German term *Ostmark* was introduced by modern historians. The lands governed by the Babenbergs and Habsburgs retained their own names, privileges and cultural individuality, but the name Österreich (the Latin form 'Austria' came into use in the 12th century) was used as the first and oldest feudal title both for the dukes and for the totality of their lands (in the later middle ages *domus Austriae* and *dominium Austriae*). After the end of the Thirty Years' War the lands under the immediate rule of the Habsburgs came to be called the Austrian lands though this name never had any constitutional significance. Constitutional unity was not achieved until the creation of the Austrian empire in 1804. From 1867 to 1918 the Hungarian territories of the Austro-Hungarian dual monarchy were no longer considered as part of Austria. The Austrian republic of the 20th century is roughly equivalent in extent to the Habsburg Austria of the later middle ages.

HISTORY

In the territories of the Austrian republic are found traces of human settlements dating back to the early Paleolithic period, and from subsequent periods several cultures are found coexisting. The entire Illyrian culture of the Early Iron Age (*c.* 800–450 B.C.) takes its archaeological name from that of Hallstatt, the principal Austrian site. Celtic tribes invaded the eastern Alps *c.* 400 B.C. and eventually founded the kingdom of Noricum (*q.v.*), while in the west (Vorarlberg and Tirol) the ancient race of Raetians was able to maintain itself. After an initially peaceful penetration during the last two centuries B.C., Roman troops finally occupied the country in 15 B.C., and the lands as far as the Danube became part of the Roman empire. South of the Danube lay the Roman provinces of Raetia, Noricum and Pannonia. Among the towns, Carnuntum (near Hainburg on the Danube) at first took precedence over the *municipium* Vindobona (Vienna). Further large settlements grew up at Brigantium (Bregenz), Juvavum (Salzburg), Ovilava (Wels), Lauriacum (Lorch, near the Enns), Virunum (near Klagenfurt), Teurnia and Flavia Solva. The peaceful development of these provinces was arrested by the invasions of Germanic tribes of Marcomanni and Quadi from the north (A.D. 166–180), and even after the repulse of these tribes by the emperor Marcus Aurelius these lands could not regain their former prosperity.

Already in the 3rd century the Roman frontier defenses were hard pressed by invasions from the Alamanni, and finally heavy attacks by the Huns and East Germans in the 5th century put an end to the Roman provinces on the Danube. There is archaeological evidence of Christian settlements in this area from the 4th century, and the biography of St. Severinus by Eugippius constitutes a unique literary source for the dramatic events of the second half of the 5th century. At that time a large number of German tribes (Rugians, Goths, Heruli and later Langobards (*see* LOMBARDS) settled on Austrian territory. In the year 488 Odoacer, ruler of Italy, brought about the emigration of part of the Roman population from these provinces.

After the departure of the Langobards (568) further development was determined by the Bavarians in their struggles with the Slavs who were invading from the east, while Alamanni settled in what is now Vorarlberg. The Bavarians were under Frankish influence, while the Slavs had Avar rulers. By the end of the 6th century the Slavs had penetrated as far as Carinthia and eastern Tirol, and after 624 a pact between the Slav tribes against the Avars led to the short-lived rule of the Frankish merchant Samo, which may also have extended over the territories of the Eastern Alps. About 700 the Enns river was the frontier between the Avars and the Bavarians, whose dukes from the house of Agilolf were, after 639, virtually independent rulers.

No doubt they, as well as the remainder of the Roman population, provided support for the Christian mission which is known to have existed *c.* 620. Among the missionaries active *c.* 700 the most important for Austria was Rupert, who founded the church of Salzburg. After the duke of the Slavs in Carinthia had placed himself under the protection of the Bavarians (before 750), the latter began to penetrate into the valleys of Carinthia and Styria, founding settlements and missions.

After defeating the Bavarian duke Tassilo III (787–788), Charlemagne led a number of attacks against the Avars (790–*c.* 796) and destroyed their khanate; the survivors settled in the eastern part of Lower Austria and soon disappeared from history. The newly created Frankish provinces on the Danube were at first administered as part of Bavaria, but only up to 799. In the regained eastern territories (the Austrian mark or march, Pannonia and Karantania or Carinthia) frequent disagreements arose in the subsequent years among the princes and between them and the royal house. The situation grew serious when to this unrest was added the threat of the kingdom of greater Moravia. Nevertheless the process of civilization was considerably advanced in Austria during the Carolingian period (790–907). Missionary activity was directed from Salzburg (from 797 an archbishopric) and Passau, while concurrently the settlement of the new lands by Bavarian and Frankish farmers went forward under both ecclesiastical and secular rulers. In 881, near Vienna, came the first clash with the Magyars, who after the destruction of the greater Moravian empire (906) became a mortal danger for the Carolingian marches. The counterattack by a large Bavarian army ended in catastrophic defeat at Pressburg (Bratislava) in 907, when the archbishop of Salzburg and Luitpold of Bavaria (the father of the duke Arnulf and the holder of great lands in the marches) were among those killed. The territories as far as the Enns river fell under Magyar domination, but in Lower Austria a certain continuity of settlement was maintained from which, after the victory at Lechfeld (955) and the further repulse of the Hungarians in the 960s, a fresh start could be made.

The Babenbergs.—In the regained territories east of the Enns, the first margrave to be mentioned is Burkhard, who lost his office as a result of his championship of Henry the Quarrelsome, duke of Bavaria. In 976 the office fell to Leopold I, of the house of Babenberg (*q.v.*), under whose rule the eastern frontier was extended to the Vienna woods. About 1002 Vienna must already have been in German hands. Between 970 and 980 new marks were created in what was later known as Carniola (or Krain) and in Styria. For a short time (*c.* 1043–63), in the east of the Austrian mark, the so-called new mark (Neumark) enjoyed an independent existence. The position of the Babenbergs was at that time still humble; their territorial rights were no greater than those of other leading noble families, and ecclesiastical immunities (those of Passau, in particular, but also Salzburg, Regensburg and Freising, as well as numerous monasteries) diminished their power within their official sphere. The bishops of Passau exercised diocesan powers in Austria and owned some important trading centres which later developed into towns.

Austria was repeatedly drawn into the disputes of the Investiture controversy (*see* GERMANY: *History;* PAPACY). In 1075 the margrave Ernest was killed fighting the rebellious Saxons. His successor Leopold II abandoned the cause of Henry IV, who raised the Bohemians against him and bestowed the mark on their duke Vratislav. In spite of their defeat at Mailberg (1082), however, the Babenbergs were able to survive. Meanwhile the cause of the so-called reform movement in the church gained ground, particularly through the influence of Altmann, bishop of Passau. Its centres were the newly founded monasteries of Göttweig, Lambach and Admont (the last named still outside the Babenberg lands, in Styria).

The reign of Leopold III (1095–1136) is particularly important in the history of Austria. In the struggle between the emperor Henry IV and his son Henry V, Leopold sided with the young king in 1106 and was rewarded with the hand of his sister Agnes; this intermarriage with the reigning dynasty not only increased Leopold's reputation but no doubt also brought him additional means of power. He was able notably to improve his position with regard to the Austrian nobility and to be the first to describe himself as the holder of a territorial principality (*principatus terrae:* Ger. *Landesfürstentum*). He strengthened his reputation with the clergy by means of generous endowments of religious communities (the foundation or restoration of Klosterneuburg and the establishment of the Cistercians at Heiligenkreuz). Toward the end of his life he obtained the rights of civic ruler of Vienna, though his residence remained at Klosterneuburg. Leopold III's achievements would have been impossible without the unremitting labour of several generations of the farming population. During the 11th and 12th centuries additional forest lands were cleared, settlements sprang up in the mountains and the demands of an increasing population caused villages to grow into towns. The fact that Austria possessed a larger number of public markets than Bavaria and also a more flourishing urban life was due to the greater productivity of the country and to its favourable situation at the intersection of major trade routes.

Formally Austria continued to be part of Bavaria, but in fact from the 11th century the rule of the Bavarian dukes no longer extended over it. In the gradual process of the dissolution of the great duchies, it was inevitable that the Babenberg territories should become a separate entity. They had enjoyed a continuity of rulers of the same house for six generations, whereas Bavaria

had changed its duke 15 times. The occasion was provided by the conflict of the German king Conrad III with the Welfs, from whom he wrested Bavaria in 1138. He bestowed the land on his half brother Leopold IV of Babenberg in 1139 and after the latter's death on Henry II Jasomirgott.

The emperor Frederick I Barbarossa put an end to the struggle for Bavaria by making Austria over to Henry Jasomirgott and his wife Theodora as a duchy, together with three countships, the actual location of which is disputed. By a document known as the *privilegium minus* (Sept. 17, 1156), Frederick reduced the obligations of the dukes toward the monarchy (attendance at royal court days only obligatory in Bavaria, provision of troops only required for campaigns against Austria's neighbours). For themselves Henry and Theodora were granted succession through the female line and the right, in the event of the premature death of their children, to appoint a candidate for the succession. To this was added the right of approving the exercise of authority by other powers within the confines of the new duchy. Against such other powers and, in particular, against the immunity of the clergy, Henry Jasomirgott was now able to exert some pressure. Yet throughout the middle ages there remained territorial dominions in Austria that were not subject to the duke. It also proved impossible to create in Vienna, now the capital city, a separate Austrian bishopric, though the two last Babenbergs made many efforts to bring this about.

Henry's son, Leopold V, was able to conclude a treaty of inheritance (1186) with Otakar IV of Styria, who had in 1180 been raised from the rank of margrave to that of duke. Through this treaty Styria came under Babenberg rule as early as 1192, as well as the Traungau (now Upper Austria), the province of Pitten (now in Lower Austria) and smaller estates in Carinthia and Carniola (Krain). With the exception of a short intermission (1194–98) the reigning Babenberg henceforth bore the title duke of Austria and Styria. During the reign of the emperor Frederick II this title was further extended by the addition of "lord of Krain" through the acquisition of fiefs of the margrave Henry of Istria, who died in 1228. The attempt to raise Austria and Styria to the status of kingdom and to place Krain as a dukedom under the rule of the new king miscarried in 1245.

During the 12th century Vienna grew into a centre for foreign trade, and the newly opened route across the Semmering pass also made access to the Adriatic easier for Austrian merchants. But the main reason for the prosperity of the two dukedoms was the completion of the colonization of the land, which was principally carried out in Austria by the religious settlements, by the great houses of the aristocracy and by the *ministeriales* and in Styria also by the house of Traungau, whose rule lasted until 1192. The house of Babenberg played only a modest part in this colonizing movement, but supported it by keeping the peace and by a policy of moderation which sought to keep Austria from involvements in imperial politics. A change came about under the last representative of the dynasty, Frederick the Warlike, whose harsh internal policy and military excursions against neighbouring lands, together with his opposition to the emperor Frederick II, led in 1237 to the temporary loss of both Austria and Styria. The crisis, however, was overcome and fresh opportunities were about to open for the duke when, on June 15, 1246, he was killed in battle against the Hungarians on the Leitha river. With him the male line of the family came to an end.

The Interregnum.—The emperor Frederick II took over the Babenberg lands and attempted to rule them by placing them in the charge of captains general. Pope Innocent IV meanwhile pressed the claim of a niece of the last of the Babenbergs, Gertrude, who in 1247 had married Hermann, margrave of Baden, a supporter of the papacy. Hermann managed to assert himself to some degree against the imperial troops but died in 1250. Hungarian and Bavarian invasions persuaded the Austrian nobility to recognize the margrave Premysl Otakar II of Moravia as duke. He entered Vienna in 1251 and in the following year married Margaret, a sister of Frederick the Warlike. King Béla IV of Hungary failed in an attempt to occupy both Austria and Styria but, through papal intervention, obtained territories in Styria at the peace of Buda (1254). In 1260 Premysl Otakar, now king of Bohemia, was able, with the support of the nobility, to take over Styria entirely; and in 1262 he was granted both Austria and Styria in fief from Richard of Cornwall, the titular German king (though admittedly only by writ). In 1270, moreover, he extended his rule over Carinthia and Carniola. At first Premysl Otakar's reign was generally popular, but later he began to encounter opposition from the Austrian nobility, probably caused in part by the dissolution of his marriage with Margaret (1260) but principally by his policy of reclaiming estates and privileges which the nobility had held since 1246. (HE. FI.; E. ZO.)

The Accession of the Habsburgs.—On the death of Richard of Cornwall the electors chose as German king the Swabian count Rudolf IV of Habsburg, who was crowned as Rudolf I on Oct. 24, 1273 (*see* RUDOLF: *German kings*). Because his personal dominions, in Switzerland and in Alsace, were comparatively small (*see* HABSBURG) and because his duty as German king in any case required that the excessive power of Premysl Otakar should be broken, Rudolf seems from the first to have wanted to secure the former Babenberg lands for his own house. He went about this purpose cautiously. First, in 1274 he questioned Premysl Otakar's right to the three duchies (Austria, Styria and Carinthia). Then, in 1276, having twice summoned Premysl Otakar to appear before the imperial diet, he placed him under the ban of the empire, led an army into Austria and defeated him. Premysl Otakar renounced his claim to the duchies and did homage to Rudolf for Bohemia and Moravia. Two years later, trying to recover what he had lost, he was defeated and killed.

In 1281 Rudolf made his eldest son Albert governor of Austria and Styria, retaining Carinthia under his own rule. Then, on Dec. 27, 1282 he raised his two sons Albert and Rudolf to the rank of princes of the empire and invested them jointly with Austria, Styria, Carinthia, the Windisch Mark and Carniola. The next year, however, this dual sovereignty was abolished, Albert receiving the territories as a hereditary possession, his brother being compensated with a sum of money. Finally, in 1286, Carinthia was detached from Albert's dominion and bestowed on Meinhard, count of Tirol.

As ruler of Austria, Albert (*see* ALBERT I, German king) had to contend with the discontent of the towns and nobles. In 1288 a rising in Vienna compelled him to flee the city, and in 1296 he granted it many of its lost municipal privileges. The Styrian nobles revolted in 1292, the Austrian nobles in 1295. There was also perennial discontent in the Habsburgs' Swiss lands, so that when his father died in 1291 Albert was unable to contend the election of Adolf of Nassau as German king. In 1298, however, Albert gained the deposition of Adolf and, defeating him at Gollheim, was himself crowned king as Albert I. In 1306, moreover, he set his eldest son Rudolf on the Bohemian throne, but Rudolf died next year and Albert was himself murdered in 1308.

Albert was succeeded as duke by his second son, Frederick (*see* FREDERICK III, German king; in Habsburg-Austrian history reckoned as Frederick I, being the first Habsburg to bear the name since the family's accession to the duchy). This Frederick in 1314 stood for election as German king, and for the next eight years Austria had to support the cost of his war with his rival Louis IV the Bavarian. In 1322, however, at the decisive battle of Muhldorf, Frederick was defeated and taken prisoner. More important for the Habsburg house, meanwhile, was the defeat of Frederick's brother Leopold I (1293–1326) by the men of Uri and Schwyz at Morgarten in 1315: henceforth, throughout the 14th and 15th centuries the Habsburg position in the Swiss cantons was to become less and less secure, until their attempt to establish their authority there had to be given up altogether.

On Frederick's death (1330) his brothers Albert II (1298–1358) and Otto (1301–39) succeeded jointly to the duchy, which under them received its first important accession of territory. In 1335 Henry, duke of Carinthia and count of Tirol, died. The emperor Louis IV enfeoffed Albert and Otto with Carinthia and the southern Tirol ignoring the claims of John of Bohemia's son John Henry, who had married Henry's daughter and heiress Margaret (*q.v.*) of Carinthia. As a result, in 1336, John of Bohemia ravaged

Austria, but he was persuaded to recognize the Habsburg succession in return for the grant of northern Tirol to John Henry.

By denying the clergy's immunity from taxation and by restricting the rights of bequest to religious bodies, Albert II tried to save from the "dead hand" of the church resources urgently needed to meet domestic and external problems. The Swiss cantons were further asserting themselves against the Habsburg power, while in Austria itself his brother Otto rose in rebellion and bad harvests and the ravages of the Black Death increased the misery of the population. In 1355 Albert tried to settle the problem of government within the duchy by a family ordinance which admitted the right of all male members of the family to rule.

Albert's eldest son Rudolf IV (1339–65) succeeded to the duchy in 1358. It was he who founded the new cathedral of St. Stephen's in Vienna (1359) and the university there (1365). He also compelled the most powerful family of the Austrian nobility, the Schaumberger, to recognize his overlordship; and in 1363 he persuaded Margaret Maultasch, whose third husband Meinhard III had died in that year, to make over the Tirol to him and his brothers. In 1359 Rudolf's forged charter, the *privilegium majus*, whereby he claimed for himself the title of archduke (*q.v.*), had caused a breach between him and the emperor Charles IV, of the house of Luxembourg, who was also king of Bohemia; but in 1364 he and Charles signed the treaty of Brno (Ger. Brünn), which provided that on the extinction of either family its lands should be inherited by the other.

The Habsburg Lands Divided.—Rudolf was in 1365 succeeded by his two brothers Albert III (1349 or 1350–95) and Leopold III (1351–86). These two, by the treaty of Neuberg (1379), partitioned the family lands, which were to remain divided between the Albertine line (Upper and Lower Austria) and the Leopoldine (Styria, Tirol, Carinthia and Carniola) until 1457. Leopold had already secured the Windisch Mark (1374) and parts of Vorarlberg (1375), and in 1382 Trieste submitted voluntarily to him to escape the encroachments of Venice. His defeat and death at Sempach in 1386 presaged the final loss of the Habsburg dominions in Switzerland.

The division of the family lands caused serious internal troubles on the death of Albert IV (1377–1404), who had succeeded his father Albert III in 1395. His son and heir, Albert V (*see* ALBERT II, German king), was only seven years old, and members of the Leopoldine line contended with one another for the rich wardship. Though in 1406 the united estates of the territories achieved a temporary reconciliation between their rulers, a vicious civil war broke out soon after. This divided Austrian society so deeply as to produce separate citizen factions in Vienna. In 1409 the emperor Sigismund mediated peace, ruling that the brothers Leopold IV (1371–1411) and Ernest (1377–1424) should share the wardship. In April 1411, however, the estates of Austria declared Albert V to have come of age and did homage to him; in June Leopold died, and Ernest, unable to resist the united loyalty of the estates, had to give up the wardship.

Albert V consolidated his position as duke by appointing advisers favoured by the estates and by securing the goodwill of the emperor Sigismund, whose daughter, the heiress to Bohemia and Hungary, he married in 1422. During his minority the duchy had been prey to civil disorder, but Albert now stamped out banditry and re-established law and order. By organizing an effective militia he checked the incursions of the Hussites who in 1428 reached the gates of Vienna. In 1438 he was crowned king of Hungary, German king and king of Bohemia in succession to Sigismund, but in 1439 he died on a campaign against the Turks—the new and growing threat to Austria.

The part played by the estates during the minority of Albert V foreshadowed their increasing influence in Austrian affairs throughout the 15th century. In the face of weakening noble authority the estates in some cases began to organize themselves for the maintenance of peace. Their assent to taxation was vital and their importance was enhanced as the merchant classes grew richer.

The Reunion of the Habsburg Lands.—Albert's successor as German king was his second cousin (Frederick V in the Habsburg-Austrian reckoning; *see* FREDERICK III, emperor), who was already duke of Styria and guardian of his own first cousin Sigismund of Tirol. Then, on Feb. 22, 1440, 20 days after Frederick's election as king, Albert's widow gave birth to a son and heir, Ladislas Posthumus (Lászlo V of Hungary), for whom Frederick likewise became guardian. Frederick's reign, however, was to be one of almost ceaseless strife with the estates, his neighbours and his jealous family. After a revolt of the nobles of the Tirol had forced him to release Sigismund from tutelage in 1446, a more serious movement broke out in Ladislas' domains in 1451, headed by the rich adventurer Ulrich Eitzing and Ladislas' uncle, Ulrich, count of Cilli, and supported by strong parties among the estates of Austria, Bohemia and Hungary. On his return from Rome, where he was crowned emperor in March 1452, Frederick was besieged in Wiener Neustadt by this league and forced to release Ladislas from his guardianship. Ladislas now became nominal ruler over his wide domains, while the actual power was wielded in Austria by Ulrich of Cilli and in Bohemia and Hungary by national regents in the persons of George of Podebrady and János Hunyadi respectively. When Ulrich was killed in 1456 the emperor succeeded to the wide estates of his house, but the death of Ladislas in 1457 opened up a period of strife and civil war between Frederick and his brother Albert VI, which was ended only by Albert's death in 1463. The Styrian and Austrian possessions were now at last reunited under Frederick, but Hungary and Bohemia, on the death of Ladislas, had broken away and had elected national kings: George of Podebrady in Bohemia and Matthias Corvinus, the son of Hunyadi, in Hungary. In 1414, moreover, the Swiss possessions of the Habsburgs finally gained their independence.

In 1485 Matthias Corvinus actually drove Frederick from Vienna, established his own residence there and incorporated large parts of Austria, Styria and Carinthia in the kingdom of Hungary. Reduced now to impotence, Frederick was forced to agree to the election of his son, Maximilian (*see* MAXIMILIAN I, emperor) as German king in Feb. 1486. Through the excesses of Sigismund, duke of Tirol, it seemed possible that the Habsburgs would lose the territory, but in March 1490 Maximilian was able to persuade Sigismund to surrender his duchy in return for an annual income. In April 1490, moreover, Matthias Corvinus died, whereupon Hungary was plunged into civil war which enabled Maximilian to regain the lost Habsburg territories with ease. For a year (1492–93) the allegiance of the Austrian lands was restored to the aging Frederick. (A. LH.)

Maximilian I (From 1493).—On Frederick's death (1493), Maximilian became the ruler of the whole Habsburg dominion. Under him it was notably consolidated by the acquisition of lands adjacent to its nucleus (Austria, Styria, Carinthia and Carniola) or to its two other major components (the countship of Tirol and the lands west of Lake Constance). In 1500, by virtue of an inheritance treaty that Rudolf IV had concluded in the 14th century, Maximilian acquired the countship of Görz (Gorizia) which opened up the Isonzo plain to the Habsburgs and brought them to the frontier of the mainland core of the Venetian republic's territory. In 1505 his help in the disputes of the Wittelsbachs of Bavaria and of the Palatinate was rewarded with the possession of new districts in the northern Tirol and the districts of Hagenau and Ortenau on the upper Rhine. In 1516, moreover, he gained towns and territories from Venice in Friuli and in the southern Tirol. He failed, however, to establish himself in the territory of the Grisons (Graubünden), which the Habsburgs had long coveted but which went over to the Swiss confederation in 1497–98.

The central area of the Habsburg dominion was in fact not Austria but the Tirol, rich in silver and copper mines and, as the bridge between Germany and Italy, the focus of a flourishing trade. Maximilian, an enthusiast for the new arts of the Renaissance, preferred the Tirol to all his territories, though he had no fixed residence there.

The constituent members of the Habsburg dominion still had no consciousness of political unity. The estates of each territory strove to maintain their traditional privileges and would not willingly renounce any of them without receiving some compensatory share in the central administration. Thus all Maximilian's at-

tempts to reform the administrative, fiscal and legal structure of his lands met with stubborn resistance from the estates. Through the Innsbruck *Generallandtag* ("general assembly of the lands") in 1518, he took the first step toward developing some common interest among the various estates in respect to their common lord, but this soon came to nothing. His attempts to raise the Habsburg dominion to a hereditary kingdom failed, while his many ventures in imperial foreign policy produced financial embarrassments which he never overcame. As the grants of money from the estates were inadequate he had to borrow heavily from the banking houses of Fugger and Welser, to whom he was obliged to pledge many lands and privileges—most notably his mining interests in the Tirol. Assistance from the princes and the estates of the empire was also meagre, as he could not overcome their suspicion that his imperial policy was a cover for the dynastic advancement of his house. His wars with France (over the Franche Comté and Milan), with Hungary and with Venice brought no lasting success, and his highest ambition, that of leading Christendom against the Turks, the enemies of his dynasty and of the empire, was never realized.

Under Maximilian, nevertheless, the future greatness of his house was founded. The marriage of his son Philip the Fair to Joan of Castile and Aragon in 1496 led to the inheritance of Spain and the Spanish territories in Europe and America by the Habsburgs. Likewise the betrothal treaties that he concluded at Vienna in 1515 were to bring Hungary and Bohemia to the Habsburgs through the marriages (1521 and 1522) of his grandchildren Maria and Ferdinand to the eventual heirs to these kingdoms, Louis and Anna, children of Vladislav of Bohemia (Ulaszlo II of Hungary).

Ferdinand I (1521–64).—On the death of Maximilian in 1519 his grandson Charles, already ruler of Spain and the Netherlands, inherited the family lands in Austria. After his election as emperor, Charles V by the partition of Worms in 1521 delegated the government of Austria, Styria, Carinthia and Carniola to his brother Ferdinand I and also by the partition of Brussels in 1522 nominated him ruler of the Tirol and the Vorlande and Statthalter in the recently acquired Württemberg. This was the origin of the division of the house of Habsburg into two great branches, the Austrian and the Spanish (*see* HABSBURG; also SPAIN, *History*).

When Louis II, king of Bohemia and Hungary, was killed at the battle of Mohács in 1526, Ferdinand took up his rights to both kingdoms under the treaty of 1515. By wise concessions to the Bohemian estates, he was able to secure their support against a rival claimant from Bavaria, and with the resources thus acquired he compelled the submission of Hungary. Together with Hungary, however, there fell to him the duty of defending Europe against the Turks, and this he was scarcely in a position to discharge. Repeated Turkish attacks, culminating in the siege of Vienna in 1529, collapsed not so much because of the resistance that they encountered as because the Turks themselves failed to support them properly, but Buda fell in 1541 and the peace of 1547 obliged Ferdinand to pay an annual tribute of 30,000 ducats to the sultan. The fertile plains of the Tisa (Theiss) and the Danube fell under Turkish rule and were to be exploited by the Turks for the next century and a half (though no attempt was made to convert the population to Islam). The Hungarian magnates, particularly John Zápolya, were meanwhile able to maintain their independence to a large degree by playing emperor and sultan off against one another. Raids by Turkish pashas, however, kept the Habsburg frontier districts in a state of permanent warfare. Ferdinand by himself could not afford to raise a sufficient force against the Turks; Charles V's other European problems prevented him from joining his brother to form a united Habsburg army; and the princes of the empire, hostile to the idea of a universal Habsburg monarchy, would not support an offensive against the Turks since the reconquest of the lost lands would have favoured Habsburg dynastic interests rather than those of the empire.

From this time on the necessity of establishing a firm frontier against the Turks determined the policy of the Habsburgs. To coordinate the resources of his territories, Ferdinand set up three central offices: the privy council (*geheimer Rat*) for foreign affairs (1527); the *Hofkammer* for financial administration (1527); and in 1556 the *Hofkriegsrat* was set up for military affairs.

These offices established themselves only slowly against the opposition of the estates, but their development strengthened the Germanization of the various nationalities under Habsburg rule. Having been constantly loyal to his brother Charles V, Ferdinand was elected king of the Romans in 1531, and after Charles's abdication (1556) he became emperor.

The Reformation raised serious problems for Austria, as conditions there were no less favourable to the spread of Lutheranism than elsewhere in the empire. The close connection between the religious upheaval and the economic and social conditions was demonstrated by the Peasants' War, which, in 1525, spread to Austria from southern and middle Germany. A typical manifestation of this conflict was the *Landesordnung* promulgated in the Tirol by Michael Gaismair as the basis for a utopian Christian republic. The initially amicable negotiations opened by Ferdinand with the Tirolese representatives, mostly peasants, came to nothing when the defeat of the peasants in Germany destroyed the movement in Austria also. While the Anabaptists were especially strong in Moravia, the Lutherans found powerful support among the Austrian nobility, which with their reciprocal support was able to strengthen its position in the estates as against the ruler. Thus, since Ferdinand wanted the nobility to back him against the Turks, he was obliged to permit the new teachings, though he refused to secularize or hand over the monasteries. Moreover, though he was a true son of the old church, Ferdinand thought that the schism resulting from the Augsburg Confession might well be healed if both sides were to show good will. Since communion in both kinds and clerical marriage were widespread in Austria and in southern Germany, he tried to persuade the pope to allow the practices. In the event, however, by summoning the Jesuits to Vienna (1551) and to Prague (1556) he in fact introduced the Counter-Reformation.

His efforts to simplify and to consolidate the central organs of administration in his dominions did not prevent Ferdinand from regarding his territories as the patrimony of his house or indeed from dividing them among his sons in his will. Ferdinand, the second son, received Oberösterreich (that is, Tirol and the Vorlande); Charles, the third son, received Innerösterreich (Carinthia, Styria, Carniola and Gorz); and Maximilian, the eldest, received all the remaining lands together with right of representing the house as a whole. This division inevitably strengthened separatist tendencies and weakened the solidarity of the estates.

Maximilian II (1564–76).—The new emperor (*see* MAXIMILIAN II), as ready for compromise as his father, was personally inclined to the humanist type of Christianity represented by Erasmus, though his office and his circumstances required a militantly Catholic attitude. To win the nobility's support in the war against the Turks, which in 1567 had suddenly flared up again, he and his brother Charles had to make notable concessions to the Protestants in the exercise of their religion, which was certainly that of the majority of the people. Moreover, in the Tirol and in the Danubian lands, where it was protected by the nobility in the estates, Protestantism began to organize itself as a church. The consent of the secular princes to this development was not necessary, since in the Roman Catholic Church in Austria the highest diocesan powers and, with them, the right of supervising the lower clergy belonged to non-Austrian ecclesiastical princes, the archbishop of Salzburg and the bishop of Regensburg. The measures prompted by the state for the reform of Catholicism by means of visitations and general ordinances on monasteries, chapters and congregations had no effect for the time being—not least because Maximilian himself still considered a compromise between the two denominations possible. He got the help of the Bohemians against the Turks by further religious concessions but his hopes of succeeding to the Polish crown on the extinction of the Jagiello dynasty in 1571 were disappointed, as it passed instead to the Turkish nominee Stephen Báthory of Transylvania.

Rudolf II and Matthias.—The shy and eccentric Rudolf II, who succeeded his father in 1576, was likewise unable to conclude any religious compromise and indeed let all control of affairs slip from his hands. Since Maximilian had not altered the partition

of the Habsburg lands made by Ferdinand I, Rudolf took over the headship of the house as well as his father's territories. As Austrian Protestantism produced no outstanding leaders at this time, the forces eager for reform were increasingly attracted to the Catholicism of the Council of Trent, and Rudolf encouraged this movement (in particular by founding new houses of the reforming orders, the Jesuits and the Capuchins). Maintaining that the religious concessions heretofore made had been granted during the prince's pleasure and so could be withdrawn, the sovereign government, with the help of the reform commission, moved against those Protestant cities which were not under the protection of the nobility in the estates. Their ministers were expelled and the citizens examined on their beliefs, those who did not freely submit themselves being driven out. The remaining inhabitants were obliged to elect Catholics to all municipal appointments, to install Catholic priests and to restore to the Catholics all the churches that they had alienated. The religious conflict became more and more a struggle for power between the estates and the absolutist sovereign. In 1594–97 the Protestant peasantry of Upper Austria rose in rebellion, their motives partly religious partly economic, and the suppression of the rising resulted in the complete restoration of Catholicism: communion in both kinds was forbidden, Lutheran books burned and hundreds of persistent Lutherans driven out without regard to the harm that this expulsion would do to the region's economy. In the Tirol also the archduke Ferdinand was able, with help from Bavaria, to suppress risings against the religious absolutism of the regime.

The first real relief for the estates and for Protestantism came with the renewal of the Turkish danger. The conclusion of peace with Persia left the Turks free to direct their energies westward again, and from 1593 to 1606 an indecisive frontier war went on between them and the Habsburgs whose forces received occasional help from Spain, from the other German princes, from the Italian states or from the pope. On taking Transylvania (*q.v.*), where the mixed Lutheran and Calvinist population had known no religious restrictions under the Turks, the Austrians began to enforce Catholicism there also. This provoked a rebellion, and in 1605 the Transylvanians elected István Bocskay as their prince instead of Rudolf. Then the Hungarians, who had always been freer from sovereign control than the Habsburgs' other subjects and were also alarmed at the progress of absolutism and the return of Catholicism, elected Bocskay likewise as their king. Bocskay invaded Moravia and threatened to spread the rising to Bohemia and to Austria. In the face of this danger a Habsburg family council, on the ground of Rudolf's incapacity, recognized his brother Matthias, the eldest of the archdukes, as head of the house and authorized him to make terms with the Turks and with the rebellious Hungarians. By the treaty of Vienna (1606) Bocskay received part of eastern Hungary and was recognized as prince of Transylvania, while Hungary itself was granted religious freedom and a constitution of its own independent of Austria, together with a specific guarantee of these freedoms from the estates of Bohemia, Moravia and the Austrian lands. These estates, united, represented a significant power as against the sovereign. The peace of Zsitvatörök (1606) with the Turks cost the emperor little, as Turkey was again threatened by Persia in the east. Besides a single payment of 200,000 ducats as compensation for the annual tribute of 30,000, only a few border fortresses and about 200 villages had to be ceded, and the major consequence of the settlement was that for the next 75 years the Habsburgs were free from worry in this quarter. This and this alone enabled the dynasty to survive the severe external and domestic crises from which it suffered in the following decades.

To compel Rudolf to a lasting recognition of these treaties, Matthias concluded an armed alliance with the Austrian, Hungarian and Moravian estates and, when Rudolf declared this confederation illegal, marched on Prague to depose him. Rudolf then allied himself with the Bohemian estates (to whom he accorded far-reaching freedoms) and finally persuaded Matthias to accept a compromise. This left Bohemia in Rudolf's hands but gave Hungary, Moravia and Austria to Matthias, together with the succession to Rudolf in Bohemia. In fact it was the estates on both sides who gained most from these transactions. In the *Majestätsbrief* of Prague (1609), Rudolf conceded freedom of conscience to all subjects in Bohemia and furthermore granted to the Protestants there the right to form themselves into a special committee, which was to be convened by their own "defensors." The privileges granted to Moravia and to Hungary amounted practically to independence. In the Alpine and Danubian lands the Catholic nobles and prelates were strong enough to limit the extent of concessions in the matter of religion, but in general the estates, who were the protectors of Protestantism, won a significant victory over the sovereign, who was protecting Catholicism.

Rudolf was far from satisfied with the compromise. At his invitation his cousin the archduke Leopold, bishop of Passau, sent a plundering army across Austria to Prague (1611). Thereupon the Bohemian estates transferred their allegiance to Matthias and compelled Rudolf to abdicate the Bohemian kingdom. Rudolf was thus left powerless, with nothing but the title of emperor. With his death in 1612 the "Habsburg Brothers war" came to an end.

Matthias, having now achieved his ambitious plans, set vigorously about the restoration of Catholicism in Austria. In this he had the assistance of the Jesuit-educated cardinal, Melchior Klesl, who had already become bishop of Vienna under Rudolf. To secure the Habsburg succession, as Rudolf had left no children and as Matthias and his brothers had none, it was agreed that the archduke Ferdinand, a son of Maximilian II's brother Charles, should be Matthias' heir, despite the strong claims made by the Spanish Habsburgs. By skilful tactics Ferdinand obtained recognition as heir from the Bohemian and Hungarian estates—even though he was known to be a convinced Catholic with tendencies to absolutism. Matthias died in 1619.

Ferdinand II (1619–37).—Before Matthias died, conflicts between Catholics and Protestants had broken out in Bohemia. In May 1618 the Protestant assembly, summoned by the defensors, had thrown the emperor's regents from the windows of the Hradcany palace and by this act, the so-called Defenestration of Prague, had given the signal for a general rising. On the death of Matthias the estates of the hereditary lands withheld their homage from Ferdinand. Their speaker, Georg Erasmus von Tschernembl, described the *Landtag* as an organ of popular sovereignty and called on the estates to take independent action. A provisional administration set up by the Bohemians sent an army against Vienna, but this was driven back by the emperor's troops. In no way discouraged, the Bohemians then proceeded, in the presence of envoys from the Austrian estates, to give themselves a constitution, to summon the other estates to send delegates to a general assembly like those of the Netherlands and of Switzerland and to proclaim the deposition of Ferdinand as king of Bohemia. Instead they elected Frederick V the elector palatine as king (Aug. 1619), the magnates putting such restrictions on his power as to render it ineffectual. Ferdinand, however, having been unanimously elected as emperor by the German princes, then discarded his predecessors' policies of compromise. In 1620, Maximilian of Bavaria, now allied with the emperor, led the army of the Catholic league through Upper Austria unopposed and, in the battle of the White Mountain, near Prague, crushingly defeated the Bohemians, who received no help from the Protestant princes of the empire. This battle is commonly regarded as the first action in the Thirty Years' War (*q.v.*). King Frederick fled, and the way was now open to radical social, political and religious changes in Bohemia. The leaders of the rising were executed and their followers exiled, while the lands of the condemned were for the most part divided among foreign nobles, who came to form a new upper class more dependent on the Habsburg dynasty and so loyal to it. The forcible re-establishment of Catholicism led to the mass emigration of the Protestants. With its legislation, judiciary and administration all controlled by the crown and the ascendancy of the Czech language broken, the kingdom of Bohemia lost its relative individuality and became simply a component unit of an integrated Habsburg monarchy.

After the reduction of Bohemia the Austrian estates could expect no gentler treatment; for Ferdinand the struggle toward religious unity meant the struggle for the true maintenance of his

lands. In a very short time the reformed faith was driven from Upper Austria, which hitherto had been the stronghold of Protestantism but which had been pledged to Bavaria as security for Maximilian's services against the Bohemians. The rising of the Upper Austrian peasantry in 1625–26 was stamped out by military force and altered nothing. The same policy was enforced throughout the rest of the hereditary lands. In Hungary, which had at first sided with the Bohemians, the emperor's son was crowned as king in 1625 but here, in view of the perpetual threat from Transylvania and the Turks, the emperor's policy could not be pursued so forcefully as in the other lands. Yet even in Hungary those magnates who went over to Catholicism soon began to enforce their new religion on their Protestant subjects.

The Habsburg house paid dearly to restore political and spiritual unity to its empire and to rebuild the basis of imperial and princely authority. It was the achievement of Ferdinand II that after long years of turmoil Austria came to be the major Catholic power in southern Germany. But his attempt to establish religious unity by force throughout the empire not only provoked the opposition of the Protestant princes but also alarmed secular and ecclesiastical princes of all denominations in the face of the Habsburg "universal monarchy" and dismayed the powers of Europe.

Ferdinand's ordinance of 1621 established primogeniture in the Habsburg family for the hereditary lands and also for Bohemia.

(W. P. F.)

Ferdinand III and the Peace of Westphalia.—When Ferdinand II was succeeded in 1637 by his son Ferdinand III the Thirty Years' War was still raging. The peace of Westphalia which brought that war to an end, was the major event of the reign. The consequence of this settlement was that the modern sovereign state in Germany developed, not on the level of the Holy Roman empire, but on that of the major territories (Bavaria, Brandenburg-Prussia, Saxony, etc.) within its boundaries. Thus it was that the Counter-Reformation and Habsburg absolutism, triumphant though they were in the Habsburg hereditary lands (including Bohemia), were prevented from taking hold on the other parts of the empire.

Leopold I, Joseph I and Charles VI.—In foreign affairs the reigns of Ferdinand III's son Leopold I (1658–1705) and of the latter's two sons Joseph I (1705–11) and Charles VI (1711–40) were dominated by recurrent wars against France and against Turkey. Within the Habsburg lands, meanwhile, these reigns saw a social and political transformation resulting from the victory of absolutism, a cultural flowering in the spirit of the Counter-Reformation and an economic development in accordance with the changed situation in Europe.

The Turkish Wars, 1663–1739.—The consolidation of the Habsburgs' rule in their own dominions was greatly promoted by successes against the Turks. The war of 1663–64 won little for the Habsburgs, but the long war that had begun with the Turkish advance to Vienna in 1683 ended in a series of victories for them. The relief of besieged Vienna (1683) was followed by the recapture of Buda (1686) and the progressive recovery of Hungary, until finally under the peace of Karlowitz (1699) the Turks surrendered all Hungary except the Banat to Leopold I. In the enthusiasm of liberation, the Hungarians at the diet of Pressburg (Bratislava; Hung. Pozsony) in 1687 renounced their right to elect their king and recognized the Habsburgs as the hereditary successors of St. Stephen. Even so the house of Austria proved unable to establish complete absolutism in Hungary, so that there remained an essential difference between the eastern and western constituents of the developing Danubian monarchy.

A further Austro-Turkish War (1716–18) ended with the peace of Passarowitz in 1718, whereby the Banat, Belgrade with part of northern Serbia and half of Walachia were ceded to Charles VI. In both these last two wars, as in the intervening war with France (*see* below), the Habsburgs had had the services of Prince Eugène (*q.v.*) of Savoy, but he was dead when Charles VI's last Turkish war was fought in alliance with Russia (1736–39). This ended disastrously, and under the peace of Belgrade (1739) all that had been gained by the peace of Passarowitz, except the Banat, had to be restored to Turkey.

The Habsburg-Bourbon Conflict, to 1740.—In their wars against the Turks the Habsburgs could rely on the support of the great princes of the empire (Charles V, duke of Lorraine, commanded the emperor's army in the relief of Vienna in 1683 and Bavarian, Saxon and Brandenburg troops fought beside them in Hungary), but some of the imperial forces had still to remain tied down in the west to guard the frontiers of Germany against aggression by Louis XIV of France (*see* DUTCH WARS; GRAND ALLIANCE, WAR OF THE). The treaty of Westphalia had already transferred some of the outlying Habsburg possessions (notably those in Alsace) to France, and subsequent French encroachments were at first successful. The balance was however restored with the Grand Alliance of 1689, concerted by William of Orange, king of England as William III, against the French supremacy. This alliance between the Catholic Leopold I and the Protestant maritime powers (England and the Netherlands) remained, with few alterations or interruptions, a basic feature of Austrian foreign policy into the middle of the 18th century. The treaty of Rijswijk (1697) at the end of the War of the Grand Alliance was the first setback for Louis XIV and a triumph for the concept of a balance of power in Europe, although the skill of French diplomacy was able to separate the allies. The peace negotiations were in any case overshadowed by the question of the Spanish succession, since Charles II the last of the Spanish Habsburgs was childless and in very ill-health. On Charles's death in 1700, Louis XIV claimed the whole of the Spanish inheritance for his grandson the duc d'Anjou (Philip V of Spain), while the powers of the Grand Alliance recognized instead the emperor Leopold I's younger son Charles, king of Spain. War broke out again and spread over Italy, western Germany and the Netherlands (*see* SPANISH SUCCESSION, WAR OF THE). The allies at first won a series of brilliant victories under the generalship of the duke of Marlborough and Prince Eugène of Savoy, but this encouraged them to make excessive claims against France. Then in 1711, the emperor Joseph I died leaving only daughters (his son Leopold, born in 1700, had died in 1701) so that his younger brother, the allies' candidate for the Spanish succession, became emperor as Charles VI. This made the English and the Dutch more disposed to negotiate with France, since the accession of Charles VI to Spain would have reconstituted the Habsburg empire of his ancestor Charles V and utterly destroyed the balance of power. Under the treaties of Utrecht, Rastatt and Baden (1713–14) the Austrian Habsburgs acquired the Spanish Netherlands (the modern Belgium), Milan, the kingdom of Naples (without Sicily, of which the duke of Savoy became king), Sardinia and the Spanish bases on the Tuscan coast, but neither Spain itself nor Spanish America, which passed to the house of Bourbon. After a subsequent Spanish attempt to regain Sicily and Sardinia had been thwarted by the quadruple alliance of England, France, Austria and the Netherlands, the duke of Savoy in 1720 surrendered Sicily to Austria, which in exchange transferred Sardinia to him. In the War of the Polish Succession (1733–35) Austria fought unsuccessfully against France, Spain and Sardinia, and was obliged by the peace of Vienna (1735–38) to surrender Naples and Sicily to Don Carlos, the future Charles III (*q.v.*) of Spain, in exchange for Parma and Piacenza.

Internal Affairs.—The period between the end of the Thirty Years' War and the death of Charles VI (1740) was the high period of Austrian baroque. The triumph of the dynasty and of the Counter-Reformation over the Protestant estates in Bohemia and in Austria, the subsequent victories over the Turks and finally the reconquest of Hungary all found expression in the magnificent palaces, churches and monasteries of the time; *e.g.*, the Belvedere and the Karlskirche in Vienna, Klosterneuburg and the Vienna palaces. The old-established noble families of the various territories, no longer able to assert themselves by independent political action, took service at court, in the army and in the administration. There they came into contact not only with members of foreign nobilities (Italians, Spaniards, Frenchmen, Walloons and Irish Jacobites) who had entered the same service, but also with members of the *bourgeoisie* who through long service as officials had acquired noble status. The mingling of these various elements resulted in a new nobility loyal to the dynasty. Likewise the

Habsburgs could rely on the support of the Catholic Church, which owed its ascendancy in their lands mainly to them (it was the church's loyalty that was later to make Joseph II's policy feasible). On the other hand the dynasty needed the good will of the estates and the church to finance its frequent and lengthy wars. For this reason and also because the sovereign, head of the Holy Roman empire and guardian of its constitution, dared not give a bad example to the other princes of the empire for their conduct toward their estates, the estates of the Habsburg lands were able to take up a stronger position against centralizing tendencies, especially in matters of taxation, minor jurisdictions and local administration, than were, for example, their counterparts in France or in Prussia.

In the industrial and commercial field the Vienna administration, already in Leopold I's time pursued a mercantilist policy like that of France, Austria's enemy and competitor. Charles VI, who had learned the importance of sea trade during his years in Spain, promoted the development of Trieste as the major port of the empire, and founded companies in Vienna and Ostend for trade with the near east and with India. The Ostend company (*q.v.*), however, provided unwelcome competition to England and the Netherlands and in 1727 Charles agreed to suspend its charter in return for the concurrence of the maritime powers in the succession law of the pragmatic sanction (*see* below). The most important economic and colonial achievement of the period was the cultivation and settlement of the territories reconquered from the Turks (for Hungary settlers were brought in from the overpopulated Rhenish districts). The Vienna city bank had been founded by Joseph I in 1706, and under Charles VI a supreme banking office (the Universal-Bankalität) was instituted. Nevertheless it was impossible even during the long periods of peace to bring order into the state finances.

The Pragmatic Sanction.—The problem of the succession overshadowed the reign of Charles VI. In 1713 Charles had determined that all his kingdoms and lands should descend as an integral whole without partition (*indivisibiliter et inseparabiliter*) to his eldest son, should he have one, or, failing a son, to his eldest daughter and then, if she should die without issue, to Joseph I's daughters and their descendants. A son was born to Charles in 1716 but died in the same year, and Charles's following children were both daughters (Maria Theresa, born in 1717, and Maria Anna, born in 1718). Accordingly, in 1720, the pragmatic sanction (*q.v.*) was published, embodying Charles's decision. On its publication the pragmatic sanction received the assent of the individual estates of the Habsburg dominions, so that it came to be a constitutional law of the developing Habsburg monarchy and a bond between the lands belonging to the Holy Roman empire (the Austrian lands and the lands of the Bohemian crown) and the lands outside the empire (those under the crown of Hungary). As the last child of Charles VI was also a daughter (Maria Amalia, born in 1724), Austrian diplomacy in the last decades of his reign was directed toward securing acceptance of the pragmatic sanction from all the European powers. Joseph I's daughters and their husbands (the electors of Saxony and Bavaria), the diet of the empire, Russia, Spain, Great Britain, France, Prussia, the Netherlands, Denmark and Sardinia did in fact recognize the pragmatic sanction. (AD. WA.)

Maria Theresa and the Wars of 1740–79.—On the death of Charles VI (Oct. 1740) the pragmatic sanction was promptly contested by two of the powers that had guaranteed it. Charles Albert of Bavaria (*see* CHARLES VII, Holy Roman emperor), raised claims on Maria Theresa's inheritance, while Frederick II of Prussia claimed most of Silesia (*q.v.*) and took actual possession of it. Frederick's victory over the Austrians at Mollwitz (April 1741) encouraged Charles Albert to insist on his own claims. The French supported him and finally Bavaria, France, Saxony and Spain joined in the attempt to partition the Habsburg lands. The War of the Austrian Succession (*q.v.*) ensued. Maria Theresa had to concede the loss of most of Silesia to Prussia but succeeded in dividing the hostile coalition and in winning the imperial crown for her husband, Francis of Lorraine, in 1745. Even though France continued the war, Austria was able, in alliance with the maritime powers, to regain the southern Netherlands and the larger part of the Italian possessions by the peace of Aix-la-Chapelle (Oct. 1748).

Alliances with the maritime powers, however, had in the past proved to be completely unsatisfactory to the Austrians, who had been disappointed both by the settlement at the end of the War of the Spanish Succession and by the maritime powers' attitude toward the Ostend company; and this disappointment had already led Charles VI to ally himself with Spain (1725) and also to attempt a *rapprochement* with France. Under the new chancellor W. A. von Kaunitz (*q.v.*) this *rapprochement* was achieved with the treaty of Versailles (May 1, 1756). Maria Theresa's consent to this alliance with Austria's previous rival was given in the expectation that France would now help her to recover Silesia. In consequence of this treaty and of the preceding convention of Westminster between Great Britain and Prussia by the so-called "diplomatic revolution," the previous system of European alliances was completely reversed. In the Seven Years' War (*q.v.*), which broke out between the realigned powers in 1756 and in which Russia also joined the Austrian side, the Prussians sustained frequent defeats but even so by the peace of Hubertusburg (Feb. 1763) Maria Theresa was compelled definitively to renounce her claims on Silesia.

The basis of the future struggle between Prussia and Austria for hegemony in Germany was thus laid. Frederick of Prussia was now determined that Austria should gain nothing in Germany that might balance the loss of Silesia. Joseph II, however, who had succeeded his father Francis as Holy Roman emperor in 1765 and was coregent with Maria Theresa of the Habsburg dominions, took advantage of the situation caused by the extinction of the Bavarian electoral line (Dec. 1777) to make a treaty in 1778 with Charles Theodore, elector palatine and heir to Bavaria, whereby Lower Bavaria and Mindelheim were to be ceded to Austria. Frederick thereupon invaded Bohemia and began the War of the Bavarian Succession (*q.v.*). Maria Theresa, without Joseph's consent, then made overtures to Prussia. Finally, with France and Russia mediating as guarantors of "the two-power system" in Germany, the peace of Teschen was signed in May 1779. By this only the easternmost corner of Lower Bavaria, the Innviertel, was conceded to Austria.

The First Partition of Poland (1772).—The alliance with Russia during the Seven Years' War had inhibited Maria Theresa from resisting Russian designs on Poland and on Turkey, though it was in Austria's interest that the integrity of both these states should be maintained. In July 1771, however, Austria had made a treaty with Turkey. Nevertheless, since Great Britain and France would take no action and as Prussia was temporarily acquiescent, the Russian empress Catherine II was able to bring her first Turkish war (1768–74) to a conclusion that established Russian influence on the northern shore of the Black sea (peace of Kuchuk Kainarji). During the Russo-Turkish war, however, Prussia, to forestall unilateral Russian action in Poland, proposed the partition of that country. Austria had already occupied the Zips (Pol., Spisz) territory in the Carpathians in 1769, and Maria Theresa, against her will, now participated in the partition treaty of Aug. 1772 (*see* POLAND: *History*). By it Austria received Galicia and Lodomeria. In 1775, moreover, to counterbalance Russia's territorial gains from Turkey and as a reward for Austria's pro-Turkish attitude Bukovina was detached from Moldavia by the Turks and ceded to Austria.

The Internal Reforms of Maria Theresa.—Beginning with Austria and Bohemia, Maria Theresa aimed to convert the Habsburg lands, still organized on a feudal basis, into a centralized state. In 1749, under the Haugwitz system (so-called after its inaugurator, the chancellor Friedrich Wilhelm Haugwitz), the central political and financial administrations were amalgamated into a *Directorium in publicis et cameralibus*, while the judiciary —formerly a department of the court chancellery—was put under an *Oberste Justizstelle*. At the instance of Kaunitz, however, the *Directorium* was dissolved in 1761, and the *Staatsrat* was established to advise the ruler on matters submitted by the high offices of the state. In the provinces the administrative functions of the

estates were absorbed in the central administration, the head of the provincial government being at the same time president of the estates. The officials of the circles (*Kreisämter*) were to implement the central policies through the provincial courts and the village authorities. The court council of trade (*Kommerzhofrat*), set up in 1762, diminished the restrictive practices of the guilds and encouraged large-scale commerce and exports (especially to the southeast). In education, the *Studienhofkommission* was set up in 1760 and a system of elementary secular education, based on enlightened Catholic principles, built up; the dissolution of the Society of Jesus in 1773 facilitated the liberation of secondary and advanced education from ecclesiastical control and the reorganization of the curriculums (the faculties of medicine receiving special attention). Although herself a strict Catholic, Maria Theresa, advised by Kaunitz and other ministers, brought the church more and more under the control of the state, government approval being required for the publication of papal bulls and for the occupation of benefices, taxes being levied on the clergy and the religious orders being subjected to supervision. In 1748 the upper estates lost the right to administer and levy taxes, and later even domain lands, hitherto exempt, became liable. Moreover, between 1771 and 1778 a series of *Robot* or work patents were introduced which regulated and restricted peasant labour services in the German and Bohemian lands. Commissions were also appointed to devise, on the basis of customary law and of common sense, a unified system of civil and criminal law and in 1768 the *Nemesis Theresiana*, regulating penal procedure, was sanctioned. Caused at least in part by the Prussian example, a great deal of the reforms aimed at the strengthening of the political and military power of the monarchy. Increased state revenues made possible the reorganization of the standing army and the building up of a reserve army; conscription was introduced and armaments were improved (under L. J. von Daun, president of the war council).

Joseph II (1780–90).—Joseph II, sole ruler of the Habsburg lands after Maria Theresa's death, made a considerable effort to restore the position in Germany to what it had been before the War of the Austrian Succession. By a close understanding with Russia, he hoped to keep Prussia's attention fixed on the east and so to hinder Frederick II from interfering in a renewed Austrian attempt to acquire Bavaria in exchange for the Netherlands. In the event, however, this attempt to augment the German element in the Habsburg dominion had to be abandoned in 1785, not so much because of the confederation of northern and middle German states that Frederick formed against it as because of French opposition, France being always interested to maintain inter-German rivalries.

Catherine of Russia, requiring Austrian support for her designs against Turkey, proposed that Russia and Austria should reach an understanding and, at a meeting at Kherson in 1787, succeeded in gaining a defensive alliance from Joseph, though he refused to commit himself further. When war had actually broken out between Russia and Turkey, however, he joined in on the Russian side (1788) and in 1789 his field marshal, E. G. von Laudon, took Belgrade ("the gate to the Balkans"). Then Prussia, as Turkey's ally, began preparations against Austria, and this threat, combined with internal troubles (*see* below), compelled Joseph's successor Leopold II to agree to terms with Turkey. An agreement reached through British mediation at Reichenbach (1790) was followed by the peace of Sistova (Aug. 1791), whereby Austria had to renounce the new conquests. Russia, however, by the peace of Jassy (Jan. 1792), won more territory on the coast of the Black sea.

The internal troubles mentioned above sprang from Joseph's precipitate reforms. In his role of "people's emperor" and "enlightened despot," he sought to integrate all his diverse lands (including Hungary) as a unitary state, to mobilize all their resources of manpower for that state's purposes and, by general social legislation, to promote the welfare of all his subjects. Local traditions and sentiments were ignored especially when they stood in the way of practical policy. If the estates were convened only to grant taxes or even not convened at all, that meant that they could no longer obstruct the progress of autocracy, while at the same time the rivalries between the component parts of the Habsburg dominion and the opposition to the process of unification were overcome. To further the new policies a carefully controlled and centrally co-ordinated bureaucracy was put in charge of all branches of the administration, and a police force with extensive powers developed. Moreover, in 1784, German was introduced as the administrative language throughout the Habsburg dominions, not with a view to germanization but in order to bind the multinational empire more closely together and to facilitate the work of the central authority, which was now represented by one vast organ, the *Vereinigte Hofstellen*. The *Toleranzpatent* of 1781, which made concessions to non-Catholics, was issued in the belief the state would benefit by securing the loyalty of all its subjects and similar motives of practical utility were behind the dissolution of the contemplative orders in 1782, their confiscated assets being used for the endowment of new pastoral institutions and bishoprics and for poor relief. The priesthood was to be transformed through the *Generalseminare* into a civil service, while marriage was declared to be a civil contract. In most cases the universities were converted into *lycées* and their curriculums adapted to the training of civil servants. On the dismantling of the feudal jurisdictions a new hierarchy of law courts (provincial courts, appeal courts and a supreme court) was established; in 1781 a general ordinance on jurisdictions was promulgated; in 1787 the first volume (*Privatrecht*) of a new code of civil law, covering Bohemia, Austria and Galicia, was issued; and in 1788 new regulations on civil and criminal procedure were introduced. As the population was still preponderantly agricultural, the emancipation of the peasantry was of major importance. Decrees of 1781–82 abolished personal serfdom and guaranteed the peasants' freedom of movement and their rights to marry without their master's authorization and to acquire land. Finally, a patent of 1789 not only regulated the peasants' obligations in money dues but also distributed taxation equitably among all landholders.

Leopold II (1790–92).—Joseph's younger brother Leopold, who succeeded him in 1790, had already, as grand duke of Tuscany, proved himself an enlightened absolutist, though not so stubborn or thoroughgoing as Joseph. Even Joseph had had to give ground in the Netherlands and in Hungary and the new emperor, confronted by general unrest and the changed European situation (*see* FRENCH REVOLUTION), had to pursue a more moderate policy throughout his dominions. He summoned the estates, quashed the *Generalseminare*, restored the universities, repealed the patent of 1789 and loosened the structure of centralization. Nevertheless the *Toleranzpatent*, the emancipation of the peasantry and the dissolution of the monasteries remained in force though the activities of the police were increased after the outbreak of revolution in France. In Hungary, the centralizing policies of Joseph II, who had refused the Hungarian coronation ceremony and had had St. Stephen's crown brought to Vienna, had caused extreme discontent. In spite, however, of strong anti-Habsburg movements there, the dynasty maintained its position in that country, and, by the federalization of the administration Leopold II was able to play off the Vlachs of Transylvania and the Slavs of Croatia against the efforts at domination made by the Magyar ruling race.

In 1789 the Austrian Netherlands had declared their independence (*see* BELGIUM: *History*). Prussia, the United Provinces of the Netherlands and Great Britain had at first recognized the new state, but the agreement reached at Reichenbach (*see* above) and the fear that revolutionary France might conquer Belgium led them to reconsider their position, particularly as Leopold acceded to the Belgian requests for the removal of foreign officials and for the participation of the estates in legislation. Then Leopold's circular of Padua (July 1791), calling on the European powers to assist the French king, clearly indicated that Austria was prepared to take the lead in Europe against the danger of republicanism. The same danger also prompted a temporary *rapprochement* between Austria and Prussia, when the two powers issued the joint declaration at Pillnitz (Aug. 1791), calling for the maintenance of the monarchical regime in France and for collective action by the European powers if the French king and his

subjects should fail to reach agreement. This declaration, however, despite Leopold's conciliatory tone, strengthened the hand of the war party in Paris, and in Jan. 1792 the French sent a note so provocative as to be an ultimatum to Austria. Austria and Prussia thereupon contracted a defensive alliance (Feb. 1792). Leopold then offered the protection of the powers to all right-minded Frenchmen against the Republican party. His death (March 1, 1792) was followed by a further French ultimatum (March 27) and then by the French declaration of war (April 20).

The Revolutionary Wars (1792–1801).—The period of the French Revolutionary Wars (*q.v.*) was one of strain, sacrifice and effort for Austria. In 1793 Russia, Great Britain, the Netherlands, Spain and Sardinia joined Austria and Prussia in the first coalition against France. Co-operation between Prussia and Austria, the two countries which were to bear the brunt of the war, was prejudiced, however, from the outset by longstanding mistrust: for example, in 1793, Prussia and Russia made a further partition of Polish territory without allocating any share of it to Austria; then in 1795 Austria and Russia decided between themselves how the rest of Poland was to be divided, without consulting Prussia beforehand on the share that Prussia was to receive. After a temporary success at the battle of Neerwinden in March 1793, by which Belgium (occupied by the French in 1792), was recovered by the allies, the military situation soon deteriorated, as the French overran the palatinate and, in the spring of 1794, Belgium again. When Prussia had signed the separate peace of Basel with France (April 1795), Austria, though assured of help from Great Britain and Russia by the triple alliance of Sept. 1795, had to sustain alone the struggle on the German front. Great efforts were required to prevent other member states of the empire from concluding separate treaties with France and to check the French drive across the Rhine in 1795. The French had, indeed, penetrated into Bavaria before the archduke Charles's victory at Würzburg (Sept. 1796) drove them back across the Rhine. The decisive blow against Austria, however, was delivered in Italy. The important fortress of Mantua, after repelling three French assaults, was forced, through starvation, to surrender, and Napoleon's lightning thrust over the Carinthian Alps compelled Austria to accept an armistice at Leoben in April. By the peace of Campoformio (Oct. 1797) Austria lost the Netherlands and Lombardy but received instead the Venetian territories, including Istria and Dalmatia. Furthermore, at the congress of Rastatt, which opened in Dec. 1797, Francis II, who had been crowned emperor in succession to his father Leopold in July 1792, had to agree to the surrender of the left bank of the Rhine to France and to accept a scheme whereby the German ecclesiastical princes were deprived of their secular authority.

Great Britain and Russia, taking advantage of Bonaparte's absence in Egypt, formed the second coalition in Dec. 1798 to crush the new France, and Russian troops were allowed to cross Austrian territory. France therefore again declared war on Austria in Feb. 1799. Prussia remained aloof from the coalition. Successes against the French in southern Germany, in Switzerland and in northern Italy, however, were followed by discord between the allies so that the planned onslaught on France came to nothing and Russia left the coalition (Oct. 1799). The Austrians were then decisively defeated by Bonaparte, back from Egypt, at Marengo in Italy (June 1800) and by Moreau at Hohenlinden in southern Germany (December). By the peace of Lunéville (Feb. 1801) France was again able to impose terms on the emperor. The approaching zenith of Napoleon's career corresponded with the nadir of Austrian fortunes. (Fr. Hu.)

THE AUSTRIAN EMPIRE

The Napoleonic Wars, 1804–1813.—When Napoleon assumed the title of emperor of the French (1804), the end of the Holy Roman empire was clearly approaching. On Aug. 10, 1804, Francis therefore assumed a new dignity as emperor of Austria—a title based on the family lands, not on tradition; and for the first time the Habsburg monarchy received formal expression. Then in 1805 Francis was drawn into the third coalition with England and Russia against Napoleon: one Austrian army was surrounded and compelled to surrender at Ulm; and the main Austrian army, together with the Russians, was defeated in the battle of Austerlitz (*q.v.*) on Dec. 2. By the treaty of Pressburg (Dec. 26, 1805) Francis not only lost all his lands in Italy, including the recently acquired Venetia, but also recognized the full sovereignty of Bavaria, Baden and Württemberg, thus virtually abdicating the last tatters of imperial dignity in Germany. The formal end came on Aug. 6, 1806, immediately after the founding of the Confederation of the Rhine; Francis renounced his title as Holy Roman emperor and was henceforth only Francis I, emperor of Austria.

Austria was still, however, regarded as the leading German state; and German patriots looked to the Habsburgs for leadership against Napoleon. The foreign minister, Johann Philipp Karl Joseph von Stadion, hoped to restore Austrian independence by an appeal to German sentiment, not by playing France off against Russia. The archduke Charles (*q.v.*), the only Austrian general of ability, reorganized the army and improved its methods of fighting; he anticipated the vaunted Prussian reform of strengthening the regular army with a militia. Stadion hoped to build up a new coalition against Napoleon and attack him in the rear while engaged in Spain. In 1809, however, Napoleon struck first. But though the Austrian armies were driven out of Bavaria, Napoleon was himself defeated when he attempted to cross the Danube at Aspern (May 21 and 22)—his first defeat. After elaborate preparations he had his revenge at the battle of Wagram (July 6), although with heavy losses. Francis feared that further war would lead to the dissolution of his empire, especially as Napoleon was promising the independence of Hungary. He therefore agreed to the peace of Schönbrunn (Oct. 14, 1809). Austria had its army restricted to 150,000 men; surrendered Salzburg and the Innviertel to Bavaria; lost part of Galicia to the grand duchy of Warsaw and part to Russia; and saw its South Slav lands annexed to the French empire as the "Illyrian provinces." Francis would never again pose as a German national leader.

Metternich (*q.v.*), the new foreign minister, personified the policy of caution and delay; he put his faith in the balance of power, not in national enthusiasm, and intended to win Napoleon's favour until such time as he should overreach himself. Thus he promoted the marriage of Marie Louise, Francis' daughter, to Napoleon in 1810. The helplessness of the monarchy was further emphasized by the financial crisis of Jan.–March 1811, when the state went bankrupt. When Napoleon planned his campaign against Russia, Metternich accepted the position of a subordinate ally (March 14, 1812). The Austrian army under Karl Philipp, prince zu Schwarzenberg (*q.v.*), was, however, a nominally independent force and avoided taking any serious part in the Russian campaign. After Napoleon's disaster in Russia, Metternich presented himself as armed mediator between Russia and Prussia on the one side and France on the other. He feared Russian predominance probably even more than French and might well have supported France if Napoleon had shown any sign of moderation. In June 1813 Napoleon agreed to an armistice, and the combatants were invited by Metternich to a peace conference at Prague. But at a preliminary meeting with Metternich in Dresden Napoleon rejected all compromise, refusing to surrender any of his hegemony in central Europe. Metternich, on leaving, said to a bystander, "Your emperor is a doomed man." Austria now entered the struggle against Napoleon (Aug. 12, 1813), and Schwarzenberg became allied commander in chief. Under him the allies defeated Napoleon decisively at Leipzig (Oct. 16–18, 1813). Metternich tried for compromise with Napoleon, or at least to salvage a regency under Marie Louise. These attempts broke against Napoleon's intransigence, and Metternich had to acquiesce in the restoration of the Bourbons.

The Vienna Settlement.—The first treaty of Paris (May 30, 1814) laid down new frontiers for Austria in Italy, and these lands were incorporated in the Habsburg monarchy as the kingdom of Lombardy-Venetia. They were given a façade of representative institutions and an appearance of autonomy under a Habsburg viceroy. Bavaria paid the price of being accepted as an ally by surrendering Tirol, Vorarlberg, Salzburg and the Innviertel to Austria. At the congress of Vienna Austria recovered the "Illyrian

provinces" which it had lost in 1805 and 1809; and, when the Polish question was settled, it recovered most of Galicia. Further, Tuscany and Modena went to Habsburg archdukes. Francis did not, however, reassert his claims to Belgium and rejected the invitation from a number of German princes to reassume the title of Holy Roman emperor. Instead Austria became a member of the German confederation, with the position of presiding power. Metternich projected a similar confederation for Italy, but this was never achieved and he had to be content with treaties of alliance, especially with Naples. In Metternich's view Austria was a "saturated power," without further territorial ambitions; and its predominance in Germany and Italy was therefore a guarantee of peace and conservatism. In reality Metternich had saddled the Habsburgs with the task of resisting the two most formidable national movements of the 19th century, yet made it impossible to ally with one against the other.

Metternich's Foreign Policy.—Though Metternich became chancellor and therefore theoretically senior minister in 1821, his influence on home policy was sporadic and for the most part ineffective. His "system" was nothing more than a grandiose name for a pacific foreign policy. Austria had nothing to gain from war and least of all, as Metternich was the first Austrian statesman to realize, from a crumbling of the Turkish empire (*see* EASTERN QUESTION). The basic object of his foreign policy was therefore to put a brake on Russia's advance in the near east; this was best achieved by talk of monarchical solidarity against the radical peril. Moreover Austrian greatness rested on treaty rights rather than on natural strength, and it was therefore Metternich's aim to keep international relations on a basis of legal principles and away from a conflict of power. Though he was doubtless genuinely afraid of a new revolutionary outburst, he exaggerated this danger in order to distract the Russians from their historical field of ambition in the Balkans. For this reason he even acquiesced in Alexander I's idealistic project of a Holy alliance (*q.v.*).

In the early days after 1815 Metternich tried to establish the congress system, a directorate of the great powers over all European affairs. Though this system brought France back to European co-operation in 1818, it broke down at the congress of Verona (1822) when Great Britain refused to join conservative intervention in Spain. Even so, Metternich succeeded in turning Russia's attention away from the Greek revolt and in giving the Ottoman empire a breathing space. There was a new alarm in 1829 when Russian armies reached the gates of Constantinople, and Metternich reluctantly planned an anti-Russian coalition. The revolutions of 1830 brought Russia back to a conservative course, and Turkey was saved by the Polish revolt. In Oct. 1833 Russia and Austria made the conservative pact of Münchengrätz (Mnichovo Hradiste): Russia got security against a new Polish rising and, in return, promised not to tamper with Turkey; and both powers agreed to co-operate against radicalism. The later eastern crisis of 1839–41 seemed less dangerous, in that Great Britain and Russia worked with Austria against a pseudorevolutionary France. Nevertheless Russian ambitions were again aroused, and Metternich, in his last years of power, was preparing the way for an Austro-French coalition against Russia. The essential condition for this was the French renunciation of ambitions in Italy, and in 1847 François Guizot gave a half-hearted impression that he would pay this price. At all events Metternich had sustained European stability for 33 years against the two dangers of a new French upheaval in the west and a Russian advance in the Balkans. His system had this flaw: he believed that Austria would collapse only if attacked from without. The revolution of March 13, 1848, was to prove him wrong.

Internal History.—The character of Austrian rule between 1815 and 1848 was determined by the bureaucratic conservatism of Francis I. He had taken fright at the failure of Joseph II and was now resolved to change nothing. His empire rested on the two pillars of bureaucracy and police. Francis dabbled in the trivial details of administration and could never be brought to have a policy. Above all he disliked any form of collective advice and preferred to play his ministers off against each other. He had in 1801 abolished the council of state created by Maria Theresa; and after experiment with less formal bodies restored it in 1808 with more limited powers. Indeed after 1815, though the highest title was "conference minister," there was no conference of ministers. Each department was rigorously restricted to its own affairs and the emperor was the only agent of co-ordination between them. Hence the stagnation of the imperial rule, which justified the verdict, "administration has taken the place of government." Francis reserved his greatest interest for the work of the police, which improved on the model of Joseph II and Napoleon. The letters even of members of the imperial family were opened; all literature was censored; and higher education was kept futile and formal. Yet the tyranny was blundering and ineffective, and the educated classes knew what was astir in the world long before 1848.

Metternich, with others, made many proposals for reforming the bureaucratic system. His panacea was a council of empire (*Reichsrat*) which, while ostensibly advisory, would check the emperor's arbitrary rule. He even proposed to give this sham parliament a pseudorepresentative character by inviting selected delegates from the provincial diets. Though Francis often promised to consider this scheme, it remained unachieved at his death in 1835. Metternich had more success in reviving provincial sentiment and in keeping the diets alive. Just as his mechanistic political philosophy preached the balance of power in international affairs, so he sought to promote "the strength that comes of diversity" within the empire. In practice this meant little more than the hope that provincial loyalties would prevent a united demand for liberal concessions. Where previous rulers—Maria Theresa, Joseph II and even Francis in his early reign—had been reformers or at least enemies of historical rights and privileges Metternich tried to restore traditions even when they were decaying. On his advice the Hungarian diet was summoned in 1825 after 12 years of absolutist rule; but he was not a success as a parliamentary statesman, and the Hungarian diet soon proved intractable In 1830 he had to call for mobilization in view of the supposed danger from France, and this increased Austria's financial difficulties Metternich's hold on the emperor was weakened and Franz Anton, Graf Kolowrat, Metternich's chief rival, won imperial favour when in 1831 he produced a balanced budget, the only one in the reign Though the conservative alliance with Russia in 1833 did something to restore Metternich's prestige, his influence on home affairs was still at a low ebb when Francis died in 1835.

Ferdinand I.—The new emperor, Francis' son Ferdinand, was feeble-minded; yet no provision had been made for a regency. Metternich planned to make himself supreme under cover of the archduke Louis, the most insignificant of Francis' brothers who was to be nominal regent. Louis was even persuaded to acquiesce in Metternich's schemes for a sort of states-general and an imperial cabinet, both under the chairmanship of the chancellor. Metternich was, however, opposed by the other members of the imperial family and by Kolowrat, who remained in control of finance. The crisis came in 1836 when Metternich tried to reduce some of the Austrian tariffs so as to enter the German Zollverein. Kolowrat threatened to resign, and the archduke John, the only liberal Habsburg, came to court to voice the opposition. Louis withdrew his support from Metternich, who lacked the resolution to force a decisive struggle. The administrative reforms were scrapped and the direction of affairs was put in the hands of a "preconference," consisting of Louis, Kolowrat and Metternich. These three were resolute only in negation; and for 13 years the destinies of the Austrian empire rested with three men whose principal motive was mutual jealousy.

The revival of provincial sentiment was, however, accelerated. The more enlightened members of the nobility had come to realize that the system of *Robot* was uneconomical even for the landowner; and many diets passed resolutions in favour of agrarian reform. Moreover, in promoting "the strength that comes of diversity" Metternich encouraged national sentiment as well as provincial, though he assumed that it would always be content with purely cultural expression. Most important was the revival of Czech literary culture in Bohemia: inspired by the romantic illusions of Johann Gottfried von Herder, this consciously elevated

Slav virtues and first challenged German cultural supremacy in the Austrian empire. The Czech national leaders, with Frantisek Palacky at their head, claimed Bohemia as their historic state and tried to turn the feudal Bohemian diet into an expression of Czech nationalism. The Bohemian nobility, though rarely of Czech origin, accepted this curious role; and in 1846 the Bohemian diet demanded the restoration of its rights as they had existed before the battle of the White Mountain. There was a similar, though less defined, revival of South Slav culture, led by the Croat poet L. Gaj and also patronized by Metternich. Here too the Croat diet gradually took on a national character, though its struggle was against Hungarian nationalism, not against German. The Croat demands for autonomy were directed to Pressburg, not to Vienna.

Hungary, which had been the real problem even in the reign of Francis, was moving steadily toward revolution. Count István Széchényi (*q.v.*), the first national leader, a great noble and conservative in social outlook, wished the aristocracy to put themselves at the head of the national movement and thus to keep it in safe channels. The symbol of this policy was the bridge across the Danube at Budapest, built with the first taxes levied on noble land. Even in this stagnant period the empire favoured economic reform; and Metternich welcomed Széchényi's program. It was, however, soon eclipsed by the extreme national agitation of Lajos Kossuth (*q.v.*), who appealed to the lesser gentry, not to the great aristocracy. Kossuth aimed to make Hungary a Magyar national state, complete with parliamentary institutions; nationalism and radicalism went hand in hand. The Hungarian diet of 1844 broke completely from governmental control; Magyar became the official language of state, with some temporary exceptions. This law created the "national problem" in Hungary and, since Croatia was subordinate to Hungary, it created the Croat problem as well.

Discontent is usually confined to a single revolutionary class; in Austria it was then universal. The aristocracy resented bureaucratic control and favoured a provincial autonomy which they supposed would be under their own control. The middle classes, capitalist or professional, desired a liberal parliamentary state, centralized and German in character. The peasants wished to end the *Robot* and to win freedom of movement. The industrial workers, concentrated in Vienna, turned against their factory conditions and, though few in numbers, could supply a violent fighting force. Perhaps most influential, the university students, in their inflated number, dreamed of a Utopian radical future. The first open revolt was in Galicia in 1846, beginning as an abortive Polish national rising. The Austrian authorities, lacking regular forces, appealed to the peasants to rise against their masters, and the result was a *Jacquerie*. The peasants, who had saved the empire with scythe and flail, were promised abolition of the *Robot;* thus the first revolutionary act came from the government itself. In Italy, too, the upper and middle classes grew out-of-hand, and the Hungarian diet of 1847, firmly under Kossuth's influence, announced a revolutionary program. Finally the diet of Lower Austria, which met in Vienna, though composed largely of bureaucrats, prepared to act as a channel of protest against Metternich, who had undeservedly become the symbol of the decaying order.

The Revolutions of 1848.—The Hungarian revolution proceeded by legal means. In Budapest a group of students announced the full radical program at the end of February. Kossuth persuaded the diet, which still met at Pressburg, to silence this radical movement by carrying its program in more regular form. The "March laws" made Hungary a Magyar liberal state, connected with the rest of the empire only by a personal union; they departed from the radical demands only in substituting a restricted property franchise for universal suffrage and thus kept the Hungarian parliament in the hands of the landed gentry.

In Bohemia a radical program was formulated on March 11. The diet of Lower Austria gave the signal for revolution in Vienna on March 13. The rising grew too formidable to be repressed; and members of the imperial family insisted that Metternich should sacrifice himself. He resigned and escaped from Vienna the following day. Kolowrat became for a few days "responsible prime minister"; when this proved too absurd he was succeeded by C. L. Ficquelmont, long designated by Metternich as his successor at the foreign ministry. Ficquelmont was in turn driven from office by student demonstrations (May 3); and the titular head then became Franz Xavier von Pillersdorff, an elderly bureaucrat with an unmerited reputation as a liberal. On March 18 Lombardy revolted against Austrian rule, and the military forces of the empire were thereafter concentrated on the war in northern Italy. Elsewhere imperial policy was confined to concessions and surrender.

Vienna was granted liberal freedoms on the morrow of the revolution; press censorship was abolished and a national guard created. On March 15 a states-general was promised at some undefined future. A fresh revolt on April 25 led to the publication of a centralized parliamentary constitution, modeled on that of Belgium. This, with its restricted suffrage and two-chamber parliament, failed to satisfy radical opinion. Pillersdorf challenged this opinion by dissolving the national guard on May 13. This provoked a further rising (May 15), and a constituent assembly, elected by universal suffrage, was promised. On May 17 Ferdinand and the imperial court fled to Innsbruck, and a committee of public safety was set up in Vienna on May 26. Hungary met with less resistance; the "March laws" were constitutionally confirmed by Ferdinand on April 11, and the Hungarian revolution was thus fully legalized. Bohemian demands did not receive full satisfaction; though Czech and German were given equality as official languages and a responsible Bohemian government promised, the union of Bohemia, Moravia and Silesia (the historic lands of the Bohemian crown) was left open (April 8). Nevertheless the imperial court at Innsbruck seemed to be planning to play Bohemia off against Vienna, as later it played Croatia against Hungary. But on June 12 the imperial commander in Prague, Alfred, first prince von Windischgrätz, seized the excuse of a radical demonstration to restore authority by force. Though the military had already won a victory at Cracow on April 25, the conquest of Prague by Windischgrätz was the first substantial success of reaction; yet national passions were so great that the defeat of the radicals, supposedly Czech, was welcomed even by radical Germans.

Imperial authority seemed to be recovering on a liberal basis. At Innsbruck a more resolute government was set up. Nominally under Anton von Doblhoff, its real leader was Johann Philipp, Freiherr von Wessenberg, an elderly diplomat of ability and genuine liberalism; it also included the Vienna radical, Alexander, Freiherr von Bach, as minister of justice. The constituent assembly met on July 22, 1848, with representatives from all parts of the empire except Lombardy-Venetia and Hungary. On the motion of Hans Kudlich, a radical student though representing a peasant district, the assembly at once considered the agrarian question and on Sept. 7 passed the Act of Emancipation, which ended the feudal system of land tenure. *Robot* was abolished, and the peasant holder was given security; the landowner received compensation partly at the expense of the state, partly at that of the tenant. The work of Joseph II was thus completed.

On July 25 Josef Radetzky's army in Italy defeated the Italians at Custoza; and on Aug. 5 Charles Albert evacuated Milan. (*See* ITALY: *History*.) An armistice was concluded, though the Austrian government was still vaguely committed to granting Lombardy-Venetia liberal conditions. On Aug. 12 Ferdinand and the imperial family returned to Vienna. The problem of Hungary was now outstanding. Wessenberg and Bach were determined to enforce a revision of the "March laws" in order to make Hungary an integral part of the empire again, especially for fiscal purposes. When the Hungarians, under Kossuth's leadership, refused this demand, the imperial court, without informing its ministers, restored to favour Josip Jelalic as *ban* of Croatia (Sept. 4). Jelalic had earlier been dismissed on Hungarian prompting; his restoration was thus a defiance of Hungary and on Sept. 11 he invaded Hungary at the head of his Croat troops.

Kossuth appealed to the constituent assembly to mediate between Hungary and the dynasty. The imperial government insisted that Hungary must first accept the unity of the empire. After a three-day debate (Sept. 17–19) the assembly refused to re-

ceive the Hungarian delegation. The government now believed that it had a free hand, and imperial troops were sent from Vienna to help Jelalic. This provoked a radical revolt in Vienna on Oct. 6. Theodor, Graf Baillet von Latour, the minister of war, was murdered and the court fled to Olmütz (Olomouc) in Moravia, followed by the majority of members of the assembly. A parliamentary rump of German radicals and Poles conducted the defense of Vienna against the forces of Windischgrätz and Jelalic. A Hungarian army failed to relieve Vienna, the provinces did not respond to Kudlich's appeal for support, and Vienna surrendered to Windischgrätz on Oct. 31. Some radical deputies and Cäsar Wenzel Messenhauser, the military commander, were shot, together with Robert Blum, a delegate from the German parliament at Frankfurt.

Schwarzenberg as Prime Minister.—On Nov. 21 a new government of forceful men was appointed, with Prince Felix Schwarzenberg, brother-in-law of Windischgrätz and former adviser to Radetzky, as prime minister. Graf Franz Seraphin von Stadion, formerly governor of Galicia, was minister of the interior. Karl Ludwig, Freiherr von Bruck, a German trader from Trieste with grandiose economic vision, was minister of commerce, and the energetic Bach remained minister of justice. The ministers were determined to assert the power of the Austrian empire against radicalism, but also against the traditional elements of weakness; their policy was reaction, not restoration. A new emperor was needed for this new policy of force. On Dec. 2 Ferdinand abdicated in favour of his nephew Francis Joseph (*q.v.*). Since there was no time to consult precedents, he became emperor in a hole-and-corner way in the castle at Olmütz; moreover, since Francis Joseph and his ministers rejected all traditional liberties and customs, this great European "crowned head" was never given a coronation until he was crowned king of Hungary after the compromise of 1867. The empire of Austria had been invented by Francis I in 1804, and no imperial coronation was ever devised. Further, Francis Joseph, being hostile to Czech and Italian claims, was never (unlike his predecessor) crowned king of Bohemia or with the iron crown of Lombardy.

Since Vienna was in a state of siege, the assembly was convened to meet at Kremsier (Kromeriz) in Moravia on Nov. 15. There the deputies drafted a constitution, which was almost completed when Schwarzenberg dissolved the assembly on March 7, 1849. The Kremsier constitution was unique among Austrian constitutional experiments in having been devised after free discussion among political leaders. Its framework was a centralized imperial authority, working with due regard for popular rights. To preserve national rights, much of the administration was left to the provinces; for the national minorities within the provinces, there were to be subordinate "circles." The Kremsier constitution showed how autonomy of national cultures could be secured under the rule of a liberal dynasty; it did not show how the dynasty could be made liberal. It was in fact the work of politicians whose revolution had already been defeated. The Kremsier constitution omitted Hungary; it was therefore useless to Schwarzenberg as a propaganda weapon. To prevent the ill effects of a constitution actually agreed upon by subjects, the assembly was dissolved on March 7. Stadion hastily drafted a constitution which treated the entire empire, including Hungary and Lombardy-Venetia, as a unitary state. This constitution was itself declared suspended until the "provisional emergency" was over.

The war with Sardinia was renewed in March 1849, and the Italian army was defeated at Novara (March 23). On April 5 the Austrian deputies were ordered to withdraw from the German national assembly. Hungary, however, was still unsubdued; and on April 14 the Hungarian parliament meeting at Debrecen deposed the Habsburgs and elected Kossuth governor. Schwarzenberg was compelled to ask for Russian help, and Russian forces entered Hungary in May. On Aug. 13 Arthur Görgey, the Hungarian commander in chief, surrendered to the Russians at Világos. Imperial rule in Hungary was asserted with great cruelty by Gen. Julius Haynau. The Hungarian constitution was abolished, and Hungary was incorporated into the unitary empire. In Nov. 1850 an emergency decree casually abolished the Hungarian tariff frontier which had been the essential mark of Hungarian separatism. Croatia, which had supported the imperial cause loyally, fared no differently; its constitution and autonomy were also abolished. "What Hungary got as punishment, Croatia received as reward."

Schwarzenberg's constructive aim in foreign policy, inspired by Bruck, was to force the entire Habsburg empire into a revived German confederation and thus to establish an "empire of 70 millions" under Habsburg leadership. He secured Russian backing against Prussian plans to create a new North German federation under Prussian leadership, and in Nov. 1850 Prussia had to agree to return to the old federal diet. But when Schwarzenberg attempted to execute his own plans at a conference at Dresden (Feb. 1851), he met with united opposition from the German princes; and this opposition was supported by Russia. The only relic of the empire of 70,000,000 was a Prussian promise that the inclusion of Austria in the Zollverein should be considered on some future occasion.

On Dec. 31, 1851, the Stadion constitution, which had remained in theoretical existence, was formally abolished, together with the provisions for individual liberty which had remained equally theoretical. An imperial council (*Reichsrat*) or sham parliament, on the lines formerly advocated by Metternich, had already been set up to advise the emperor on legislation, but it never functioned to any serious purpose. Since absolutism was the keynote of the new system, Francis Joseph (like Francis before him) would not have his absolutism curtailed even by an advisory council. Karl Friedrich, Freiherr Kübeck von Kübau, a former liberal, on whose advice the patent of Dec. 31, 1851, had been made, hoped himself to supplant the all-powerful ministers who had governed the empire since the defeat of the revolution. But though ministerial power was certainly weakened, Kubeck did not benefit. Once more, as in the reign of Francis, the emperor became the sole instrument of co-ordination between ministers strictly confined to their own departments.

The Bach System.—The evil effects of Kübeck's patent were not apparent so long as Schwarzenberg's strong personality maintained his position as prime minister. But when he died in April 1852, no new prime minister was appointed, Francis Joseph himself attempting to act as such. The outstanding minister who remained from Schwarzenberg's powerful team was Bach, now minister of the interior. He carried the authority of centralized administration to the most extreme parts of the empire, which was ruled as a unit for the first time in its history. Though originally radical in outlook, Bach accepted an alliance with the clergy to maintain his position at court. Education was put back under clerical influence; and a concordat (Aug. 18, 1855) gave the Roman Catholic Church a highly privileged position. Civil marriage was abolished, and the concordat even contained a promise that no confessional laws would be altered without the consent of the Vatican. The Bach system was administered by German bureaucrats and aimed to make the Austrian empire a centralized German state. It was, however, disliked by the German middle classes because of the lack of liberal institutions and still more because of the unstable finances caused by the great burden of armaments. The greatest hostility to the system was in Hungary where the German administrators were known as "Bach hussars." Hungary remained under martial law as did Lombardy-Venetia, until 1857.

Buol's Foreign Policy.—A forceful foreign policy had been an essential part of Schwarzenberg's outlook. This had restored Austria's position in Italy and Germany, but had not freed from dependence on Russia. Karl Ferdinand, Graf von Buol-Schauenstein, Schwarzenberg's successor as foreign minister, ignored this dependence. In 1853, when the eastern crisis opened which led to the Crimean War (*q.v.*), he refused to allow Russia a free hand or even to partition the Turkish empire with it. On the other hand he hoped to acquire the Danubian principalities (the later Rumania) for Austria; and Austrian forces occupied them in July 1854. Just when Buol's course seemed set for war with Russia the Austrian generals intervened and insisted that the army was not strong enough to fight Russia in Galicia. Buol

therefore had to try to retain the friendship of the western allies, Great Britain and France, by promises that were always empty. On Dec. 2, 1854, he signed a treaty of alliance with them and received in return a French guarantee of tranquility in Italy for the duration of the war. But when the ensuing conference at Vienna between the belligerents (Feb.–April 1855) proved abortive, Buol evaded action, leaving the field free for Austria's opponent, Sardinia, to win the allies' good will by supporting them. Both sides blamed Austria for its inactivity, and at the congress of Paris (Feb.–March 1856) Austria was isolated: the Austrian troops had to withdraw from the principalities, and Buol had to hear Austrian rule in Italy denounced in full congress by the Sardinian delegate, Cavour.

The estrangement from Russia shattered the keystone of Metternich's foreign policy which had given the Habsburg monarchy 40 years of security in Europe. Russia was bent on disrupting the coalition of Great Britain, France and Austria; and, in its resentment against Austria, gave cautious approval to the revolutionary projects of Napoleon III to remodel the map of Europe. Napoleon and Cavour were therefore free to provoke Austria into war, and Buol did nothing to prevent them. He rejected the congress proposed by Russia (March 1859), failed to secure the alliance of Prussia, and finally launched an ultimatum to Sardinia demanding that it should disarm (April 19, 1859). The statement that the ultimatum was sent by the generals or the court without Buol's knowledge is a legend, invented to conceal the incompetence of Austrian diplomacy. The Austrian army in Italy was defeated at Magenta (June 4) and at Solferino (June 24). Francis Joseph then made the armistice of Villafranca (July 12) with Napoleon, by which he surrendered Lombardy, retaining Venetia. This was confirmed by the treaty of Zürich, signed on Nov. 10, 1859.

The October Diploma.—Defeat in war discredited the absolutist system. Johann Bernhard, Graf Rechberg-Rothenlöwen, a disciple of Metternich, succeeded Buol, and Agenor Goluchowski, a Polish aristocrat, succeeded Bach (Aug. 1859). The intention was to return to the historic conservatism of the era before March 1848, when the aristocracy co-operated in theory with the crown. Symbol of this revived aristocracy was the "reinforced *Reichsrat*" (May–Sept. 1860); the intention was to increase the *Reichsrat* by members from the provincial diets, but since these had also been abolished in 1849, the additional 38 members (2 for each province) were nominated by the emperor. In July 1860 the reinforced *Reichsrat* submitted a report advocating the reconstruction of the empire on a basis of aristocratic federalism. Though Francis Joseph was now much under the influence of the Old Conservatives (spokesmen of the Bohemian and Hungarian aristocracy), he paid no serious attention to this report. But, anxious to create a good impression before meeting the Russian emperor and the king of Prussia at Warsaw (Oct. 21, 1860), he had an aristocratic constitution hastily drafted and formally published as the "October diploma" (Oct. 20). This diploma revived the provincial diets, under aristocratic control; these diets were to advise on all legislation except in a few matters which were reserved for the central *Reichsrat*. The *Reichsrat* was itself to be mainly drawn from the diets, and it too was to have only advisory powers. The Hungarian diet was to proceed "according to its former constitution"; regulations for the other diets were to be issued later. Finally, matters concerning the provinces other than Hungary were to be discussed in common without the Hungarians. This was the first premonition of dualism.

The October diploma did nothing to satisfy the Hungarian demand for the constitution of 1848, as formally acknowledged by Ferdinand I. It was equally rejected by the Germans who disliked both its federal and its aristocratic character. Saddled with debt and with war expenses, the empire was especially vulnerable to the opinion of the German capitalists in Vienna, who were now more hostile than they had been to the Bach system. The Hungarian Old Conservatives persuaded Francis Joseph that the Hungarians would accept the October diploma if they could have proof of his liberal intentions in the rest of the empire. In Dec. 1860 Goluchowski was dismissed and his place taken by Anton, Ritter von Schmerling, whose task it was to give the non-Hungarian lands a stronger dose of liberalism.

The February Patent.—Schmerling was a bureaucrat with some liberal leanings and strong centralist convictions. He had defended the unity of the Habsburg lands against the German radicals at Frankfurt in 1848 and was now determined to defend this unity against the Hungarians. On Feb. 26, 1861, he produced a patent which, ostensibly a gloss on the October diploma, in reality reversed it. The diets lost most of their powers; the *Reichsrat*, though still elected by the diets, became a parliament with two houses (*Herrenhaus* and *Abgeordnetenhaus*), legislating for the entire empire. Yet a "narrow *Reichsrat*" was also defined to deal with non-Hungarian affairs.

The franchise had previously been designed to benefit the great landowners; now both it and the constituencies were rigged to benefit the German middle classes. This was the system of "electoral geometry," by which the Germans became predominant in the *Reichsrat*. The February patent lacked many essential constitutional securities; it did not even provide for parliamentary control over finance or legislation. Still it was accepted by most German liberals as an excuse for making their peace with the dynasty.

The Hungarians, however, refused to be satisfied with anything less than the restoration of the laws of 1848. When the Hungarian diet met in April 1861 it refused to elect representatives to the *Reichsrat;* and it was dissolved in August after presenting an address of protest to Francis Joseph. Schmerling announced: "We can wait"; and Hungary was once more brought under martial law. This policy continued to receive the support of the German liberals. Other nationalities were less subservient: the Croat diet was also dissolved in 1861 when it too demanded the restoration of its ancient privileges; the Czech deputies withdrew from the *Reichsrat* in 1863. Only representatives of the Saxons in Transylvania maintained the illusion that the *Reichsrat* was the parliament of a united empire.

In order to win the support of the German liberals, Schmerling advocated a forward policy in Germany, putting Austria at the head of the movement for German unification. Rechberg, still foreign minister, would have preferred a conservative co-operation with Prussia, but he was overborne by Schmerling. In 1863 Francis Joseph attempted to inaugurate German reforms by summoning a meeting of German princes at Frankfurt; this attempt broke against Prussia's refusal to attend. In 1864 Austria was drawn into the war against Denmark for Schleswig and Holstein; the peace of Vienna (Oct. 1864) ceded the duchies to Prussia and Austria jointly. Rechberg tried once more to make a real alliance with Prussia; when he failed his usefulness was over, and he resigned in Oct. 1864. Francis Joseph was equally weary of Schmerling's liberalism, which had failed to conciliate or to subdue the Hungarians. When Ferencz Deák (*q.v.*) the Hungarian leader, put forward proposals which held out hopes of a successful compromise, Francis Joseph dismissed Schmerling and replaced him with a conservative "ministry of counts," headed by Richard, Graf Belcredi (*q.v.*).

Belcredi's Ministry, 1865–67.—Belcredi and his fellow counts swung back, with more sincerity, to the aristocratic conservatism of the October diploma. The *Reichsrat* was dismissed, the February patent "suspended," and the provincial diets were once more packed in favour of the great landowners. Belcredi hoped that, if he increased the powers of the provincial diets, the Hungarians would be satisfied with the same rights as the others; but the essence of the Hungarian claim, founded in history as well as in law, was that Hungary was unique. Thus Belcredi had nothing better to offer than Schmerling's policy of waiting; yet this policy had caused Schmerling's dismissal. Belcredi had been appointed to settle with Hungary in view of the approaching war with Prussia; instead he welcomed war with Prussia as an excuse for not settling with Hungary. The ostensible ground for war with Prussia was a dispute over Holstein, but the real cause lay in the struggle for mastery in Germany. The Austrian government might have had Italian neutrality in exchange for surrendering Venetia. It was too proud to make this sacrifice, yet signed a

treaty with Napoleon III (June 12, 1866) by which it promised to surrender Venetia after the war. Austria had therefore to fight a war on two fronts (*see* SEVEN WEEKS' WAR). Though the archduke Albert (*q.v.*) won a barren victory over the Italians at Custoza, the main Austrian army was routed by the Prussians at Sadowa (Königgrätz) on July 3. By the peace of Prague (Aug. 23) Austria surrendered Venetia and was excluded from Germany. It was only due to the grace of Bismarck that it remained a great power. As a result of the war of 1866 Austria became the second "Sick Man" of Europe.

Immediately after Sadowa, negotiations were renewed with Deák and with his chief supporter, the elder Gyula Andrássy (*q.v.*), who desired a partnership between Germans and Magyars to hold down all other nationalities of the empire. Belcredi would not accept this program; he still hoped to balance the other provinces against Hungary and therefore urged them to formulate demands. These delaying tactics no longer satisfied Francis Joseph, who was eager for revenge on Prussia. In Oct. 1866 Friedrich Ferdinand, Graf von Beust (*q.v.*), formerly prime minister of Saxony, became foreign minister; and his concern too was to settle with Hungary as quickly as possible. He persuaded Francis Joseph that a settlement was possible if negotiations were limited to Hungary (Feb. 3, 1867). Belcredi resigned, and Beust was left alone with a few officials to wind up old Austria.

The Compromise of 1867.—The agreement reached between Beust and Andrássy was a compromise between the emperor and Hungary, not between Hungary and the rest of the empire. Indeed the peoples of the empire were not consulted, despite Francis Joseph's promise at the time of the October diploma not to make further constitutional changes without the advice of the *Reichsrat*. Hungary received full internal autonomy, together with a responsible ministry, according to the "March laws" of 1848. In return Hungary agreed that the empire should still be a single great state for purposes of war and foreign affairs. Francis Joseph thus surrendered his domestic prerogatives in Hungary, including his protection of the non-Magyar peoples, in exchange for the maintenance of dynastic prestige abroad. The "common monarchy" consisted of the emperor and his court, the minister for foreign affairs and the minister of war. There was no common prime minister (other than Francis Joseph himself) and no common cabinet. The common affairs were to be considered at the delegations, composed of representatives from the two parliaments. There was to be a customs union and a sharing of accounts, which was to be revised every ten years. This decennial revision gave the Hungarians recurring opportunity to levy blackmail on the rest of the empire.

The Compromise (*Ausgleich*) came into force when passed as a constitutional law by the Hungarian parliament in March 1867. Francis Joseph would not have troubled to get the consent of the rest of the empire. Andrássy, however, insisted that there should be a formal approval; and the "narrower *Reichsrat*" of the February patent was therefore summoned by Beust in May 1867. The *Reichsrat* was only permitted to confirm the compromise without amending it. In return for this the German liberals who composed its majority received certain concessions, which were added to the February patent as "constitutional laws." The rights of the individual were secured and a genuinely impartial judiciary was created. Freedom of belief and of education were guaranteed—a breach of the concordat of 1855 with Rome, which now remained an empty form. Nothing, however, was done to modify the system of electoral geometry. In the contemporary phrase the German liberals were so eager "to climb on to the driver's seat of the state coach" that it escaped their attention that they were not allowed to hold the reins. The ministers were still responsible to the emperor, not to a majority of the *Reichsrat*.

The official name of the state shaped by the Compromise was Austria-Hungary. The kingdom of Hungary had a name, a king, a history of its own. The rest of the empire was a casual agglomeration without even a clear description. Technically it was known as "the kingdoms and lands represented in the *Reichsrat*" or, more shortly, as "the other Imperial half." The mistaken practice soon grew of describing this nameless unit as "Austria" or "Austria proper" or "the lesser Austria"—names all strictly incorrect until the title "empire of Austria" was restricted to "the other Imperial half" in 1915. These confusions had a simple cause: the empire of Austria with its various fragments was the dynastic possession of the house of Habsburg, not a state with any common consciousness or purpose.

AUSTRIA-HUNGARY

The Bourgeois Ministry.—In Dec. 1867, when the constitutional laws had been passed, Beust received the empty title of imperial chancellor, though in reality no more than foreign minister. On his advice Francis Joseph appointed a "bourgeois ministry" or "ministry of citizens" (in contrast to Belcredi's "ministry of counts"), drawn from the German liberals of the *Reichsrat* and with Karl Wilhelm (Carlos), prince von Auersperg as minister-president. This bourgeois ministry continued the work of liberal reform. It restored civil marriage (March 1868), regulated secular education and instituted universal military service. But Austria could not be governed solely for the benefit of the German middle class. The Czechs were indignant at the revival of electoral geometry and at their exclusion from all share in political life. Their deputies had boycotted the *Reichsrat* when it was renewed. On Aug. 23, 1868, they issued a declaration of their aims. They asked for equal national rights for the Czechs in Bohemia and for electoral reform—demands that could have been met within the framework of the existing unitary system. But, inspired by the Hungarian model and envious of Hungarian success, they also demanded the unification of "the lands of St. Wenceslas" (Bohemia, Moravia and Silesia) and the same independence for this "Great Bohemia" as Hungary possessed. This would have ended German predominance in Austria and destroyed Hungary's position as Austria's only partner. The ensuing 50 years of imperial history were determined by the choice of the emperor and of the Germans to surrender to Hungarian dictation rather than call in the Czechs as associates.

The bourgeois ministry was divided in its attitude to the Czech demands. The middle-class Germans, who were in the majority wished to give the Czechs an intransigent answer and to break their boycott of the *Reichsrat* by holding direct elections in the constituencies without the intervention of the Bohemian diet. The minority, led by Eduard, Graf von Taaffe (*q.v.*), a boyhood friend of the emperor's, and by the Polish Count Alfred Potocki, wished to offer the Czechs local concessions in Bohemia in exchange for their recognition of the central state and their attendance at the *Reichsrat*. Policy swung to and fro. In Sept. 1868 Taaffe became prime minister without having the support of the majority in the ministry. In Dec. 1869 the German ministers again urged direct elections to the *Reichsrat*. Taaffe appealed to the emperor who refused to support him; whereupon Taaffe and Potocki resigned. A purely German ministry was then formed under Leopold Hasner. The *Reichsrat*, however, failed to carry direct elections by the necessary two-thirds majority, and the Poles, Rumanians, Slovenes and Italians withdrew from it. The German ministers wished to engage in a general struggle with the other nationalities and asked the emperor to dissolve all the diets whose members had withdrawn (April 1870). This was too much for Francis Joseph and the German ministers resigned in their turn. Potocki now formed a cabinet chiefly of imperial officials and tried to arrive at a compromise which should satisfy both Czechs and Germans. He dissolved all the diets and also the *Reichsrat*, but new elections did not produce any more favourable result. The Czechs thought they were in sight of complete victory and would be satisfied with nothing less than the kingdom of St. Wenceslas; the Germans refused to weaken the centralized state or even to grant national concessions to the Czechs in Bohemia. When the *Reichsrat* met in Oct. 1870 Potocki was censured both for negotiating with the Czechs and for failing to reach an agreement with them. Potocki resigned (Nov. 24), but since no new ministry could be found he remained in office until Feb. 1871. His only memorable act was the formal denunciation of the concordat with Rome in July 1870.

The Franco-German War.—Beust had been made foreign minister in 1866 and had himself pushed through the Hungarian

Compromise in 1867 in order to prepare for a war of revenge against Prussia. For this an alliance with France was essential, and negotiations were conducted from 1867 until 1870. In 1867 Napoleon III and Francis Joseph met at Salzburg; later the archduke Albert, the Austrian commander in chief, visited Paris and a French general came to Vienna for military conversations. Agreement was never reached. Beust wanted a general alliance which would give Austria-Hungary security against Russia as well as against Prussia. Napoleon wished to keep his hands free in order to make concessions to Russia in the near east at the decisive moment. His eyes were turned solely against Prussia. Beust, on the other hand, could not openly take a line involving the loss of German territory to France if he wanted Austria to recover its position as a German power. Most of all, the negotiations broke down on the question of Rome (*see* ITALY: *History*): the Austrian generals would not face a new war with Prussia unless secure from an Italian attack; the Italians would not enter the alliance unless French troops were withdrawn from Rome; and Napoleon could not give up the pope because of clericalist opinion in France. When the crisis broke in July 1870 France and Austria-Hungary were not allies. Beust knew that this was his last chance against Bismarck and advocated war or at least armed neutrality. He was opposed by the Austrian generals who insisted that the army was not ready; also, the Germans in Austria now regarded Bismarck as their national hero. The final push came from Andrássy, now Hungarian prime minister, who, realizing that Austro-Hungarian dualism, with all its advantages for Hungary, was due solely to Prussia's victory in 1866, was determined that this victory should not be reversed. Austria-Hungary remained neutral, at first provisionally, then without reserve. By a fine irony dualism, Beust's sole success as a statesman, was the decisive barrier against the success of his foreign policy.

The Czech Crisis of 1871.—Once the policy of revenge was abandoned there was no purpose in trying to present Austria as a German state, and the Compromise with Hungary also lost its justification. For a moment Francis Joseph considered a return to thoroughgoing centralism under Schmerling; this would have provoked an immediate Hungarian resistance and, besides, the Germans would no longer support Schmerling. Francis Joseph therefore turned to the federalist alternative and aimed at a settlement with the Czechs. On Feb. 5, 1871, Karl Siegmund, Graf von Hohenwart, a leading German clerical, became prime minister, with Albert Schäffle as minister of commerce and the real inspirer of policy. Schäffle, a radical from Baden, was one of the few Germans who had retained the genuine idealism of 1848. He wished to transform the Habsburg monarchy into a federation of equal peoples and to extend the suffrage in order to lessen national passions which were, he believed, predominantly middle class. Hohenwart and Schäffle at first attempted to proceed by slow stages. In April 1871 bills were introduced into the *Reichsrat* increasing the autonomy of the provinces; these bills were rejected by the German majority. Hohenwart and Schäffle then decided to face a full settlement with the Czechs. After some months of negotiations an imperial rescript (Sept. 12) proposed to revive the historic rights of Bohemia, together with full national equality for Czechs and Germans in Bohemia. When this compromise was accepted, Francis Joseph would be crowned king of Bohemia in Prague. The Czech leaders thought that this was the beginning of a bargaining such as had preceded the Hungarian Compromise and therefore answered (Oct. 10) with 18 "fundamental articles," which insisted on the unity of "the lands of St. Wenceslas." Moreover the Czech leaders knew that their national movement had as yet little real strength; they doubted whether Bohemia could really hold its own against Hungary and the nameless "imperial third." They therefore demanded a federal system for all the imperial lands except Hungary, with the *Reichsrat* reduced to a congress of delegates. Yet this federal system would not have solved the national question: the provinces were historical, not national, units, and the national struggle would simply have been fought in each province as it was already being fought between Czechs and Germans in Bohemia. Now as always the Czechs would not contemplate a redivision of the Habsburg lands on national lines, for they would have then lost their "historic" Bohemia. The Germans would have gained, as a nation, from such a national redivision; but they in their turn would not dismember the unitary state centred on Vienna, which they regarded as historically theirs.

The Hohenwart-Schäffle bargaining with the Czechs provoked open German opposition, and there were riots in the streets of Vienna. Hohenwart and Schäffle were men of the study, not practical politicians, and they were nonplused by this appeal for force. Andrássy had throughout observed their policy with hostility; if the Czechs achieved their aim Hungarian predominance would be at an end. When Francis Joseph asked for his advice he came to Vienna with simulated reluctance. He challenged Hohenwart whether he was prepared to break the German opposition by force: "If not, do not begin this policy." The Czech fundamental articles were abruptly rejected; and the Hohenwart ministry was dismissed (Oct. 27, 1871). Andrássy's triumph was complete when on Nov. 14 he took Beust's place as foreign minister.

Andrássy.—A new version of the "bourgeois ministry," composed of German middle-class liberals, was restored with Prince Adolf Auersperg as prime minister. These Germans were in office by favour of Andrássy, not from their own strength or merits. Indeed Hungary, by perpetuating the national disputes within Austria, was sole gainer from the crisis of 1871. The German ministers were themselves disillusioned, barren and often corrupt. Their only achievement (Feb. 1873) was that they at last managed to institute direct elections for the *Reichsrat*, though of course retaining the complicated franchise with its four *curiae* or categories of constituency. This change defeated the Czech policy of abstention; but the German liberals made no effort to make their return to the *Reichsrat* easy and continued to treat Bohemia as Hungary had been treated in the days of the "Bach hussars." The German ministers, closely linked with Viennese capitalists, were greatly weakened by the financial crisis of May 1873, especially as some ministers were involved in the attendant scandals.

The great issue of these years, however, was in foreign affairs. Now that Hungary was secure, Andrássy, once a revolutionary, had become conservative and wished to preserve the Compromise of 1867 indefinitely. This involved friendship with the new Germany and the maintenance, at the opposite end of the frontier, of the Ottoman empire—for which a pacific Russian policy was essential. The League of the Three Emperors (*Dreikaiserbund*) of 1872, by which Francis Joseph and the German and Russian emperors agreed to work together for peace, gave expression to this policy, but in 1875 upheavals in the Balkans threatened to change Russia's course. (*See* EASTERN QUESTION.) The Andrássy note (presented on Jan. 31, 1876) proposed reforms which the Porte might adopt; when this failed, Andrássy was faced with the inevitable outcome that Russia would attempt to impose reforms on Turkey by force. Like Metternich before him, though for very different reasons, Andrássy was convinced that Austria-Hungary was a "saturated state"; the Russian offers of partition therefore did not attract him. Since Russia could not be restrained altogether, Andrássy's object was to keep its aims within modest limits; this seemed to be achieved by the two secret agreements of Reichstadt (Zákupy) in July 1876 and Budapest in Jan. 1877, agreements more important for what they excluded than for what they contained. Russia, renouncing "the great partition," agreed to be content with Bessarabia and in return gladly acquiesced in Austria-Hungary's acquiring Bosnia and Hercegovina. Andrássy therefore watched in neutrality the Russo-Turkish war of 1877–78, despite the fire-eating protests of Francis Joseph and the Austrian generals who were eager for war. In Feb. 1878, with the war won, Russia forgot its promised restraint and imposed on Turkey the treaty of San Stefano, which created a Great Bulgaria. Andrássy protested against the treaty, but he was still set against going to war and evaded an alliance with Great Britain until it was clear that the Russians had given way. At the congress of Berlin (*q.v.*) Bulgaria was dismembered, and Russia accepted its earlier program. Turkey was given another generation of existence, and Austria-Hungary along with

it. Neither empire owed this breathing-space to its own strength; they had been saved by British resolution, by Russian weakness and most of all by Bismarck's opposition to a general war.

The problem of Bosnia and Hercegovina remained. Turkish rule could not be restored, and Austria-Hungary could not allow the aggrandizement of Serbia, already a dangerous example of a South Slav national state. Andrássy had to acquiesce, with extreme reluctance, in the occupation of Bosnia and Hercegovina by Austria-Hungary; he genuinely hoped that within 30 years the Ottoman empire might be reformed and that then the provinces might be restored to Turkish rule. Since the provinces were occupied, not annexed, they could not be included in either Austria or Hungary; they therefore became the only territorial expression of "the common monarchy" and provided a substitute for the colonial outlet by which in the later 19th century the great powers displayed their civilizing energy. The German ministers objected strongly to this addition of new Slav populations to an empire in which Germans were already outnumbered, and voted against Andrássy's policy in the delegations. This was a breach of the implied bargain with Francis Joseph, by which the Germans had been allowed to preserve their dominant position at home in compensation for leaving foreign policy as an imperial prerogative. In Aug. 1878 he broke with the bourgeois ministry, though they remained in office until suitable successors could be found.

Francis Joseph was also dissatisfied with Andrássy, since his foreign policy seemed always to be determined by Hungarian and not by dynastic interests. Francis Joseph had forgotten the lessons of caution taught by the defeats of 1859 and 1866; he began again to imagine himself the ruler of a great state. Andrássy managed, however, to impose an effective barrier against any Habsburg expansion in the Balkans before he resigned. This was the Austro-German alliance of Oct. 1879, also more important for its omissions than for its contents. Certainly Germany promised to support Austria-Hungary in case of a direct Russian attack; this was a commonplace long accepted even by Russia. But Germany did not promise to support Austro-Hungarian plans in the Balkans. Indeed a conservative Austro-Hungarian foreign policy was the essential condition of the alliance. The alliance had an important domestic consequence: since Germany guaranteed the dual system, Hungary no longer needed the friendship of the Germans in Austria and could allow an attempt to conciliate the Czechs and other Slavs, such as Andrássy had forbidden in 1871. Thus the alliance with Germany ended German predominance in Austria.

Taaffe as Prime Minister.—In Aug. 1879 Taaffe took office as prime minister above the parties, an imperial minister (*Kaiserminister*) as he called himself. His object was to persuade the Czechs to attend the *Reichsrat* in return for concessions in the national question. This object was achieved in April 1880 when Czech and German became the languages of "the outer service" in Bohemia. The Czechs returned to the *Reichsrat* and, though their spokesman made a formal statement at the beginning of each session disputing the competence of the *Reichsrat* to legislate for Bohemia, they in reality displaced the Germans as the party "loyal to the constitution." The Czechs were further rewarded in 1882 by a lowering of the franchise to include all who paid five florins in direct taxation. This enfranchised the more prosperous Czech peasants and so weakened the hold of the German middle class. An even more striking Czech gain was the division of Prague university into separate Czech and German establishments. Taaffe did not imagine that he had solved the national question; in his own words, he aimed "to keep all the nationalities in a balanced state of mild dissatisfaction." This cynical lack of system gave Austria about 12 years of political calm such as it had not known since Metternich's days.

In the Taaffe era Austria-Hungary seemed to recover independence as a great power. Gustav Siegmund, Graf Kálnoky (*q.v.*), foreign minister from 1881 to 1895, had no faith in Russian pacific intentions. Though drawn by Bismarck into a renewed League of the Three Emperors (June 1881), he also made secret treaties with Serbia (1881) and with Rumania (1883) which were designed to exclude Russia from the Balkans. Further, the triple alliance with Germany and Italy of May 20, 1882 was incipiently an anti-Russian coalition and was turned to good use by Kalnoky when the Eastern question was reopened in 1885. He refused to accept Bismarck's advice to partition the Balkans with Russia. Instead he promoted the two Mediterranean agreements with Italy and Great Britain (March and December 1887) which set up an effective barrier against Russia and assisted a peaceful outcome of the confused Bulgarian crisis. Still Kálnoky's pertinacity had an unexpected influence on home affairs. Bismarck was unshakably resolved not to be drawn into war with Russia for the sake of Austro-Hungarian interests in the Balkans; and, to emphasize his resolve, asserted his indifference also concerning the fate of the Germans in Austria and actually encouraged Taaffe's concessions to the Czechs.

The more extreme German nationalists, feeling themselves abandoned both by the emperor and by Germany, redoubled their extremism. In 1882 their "Linz program" proposed that Galicia and Dalmatia should be made autonomous and that the rest of constitutional Austria should become exclusively German in character with the backing of the German *Reich*. German nationalism also took on, for the first time, an anti-Semitic form, inspired by Georg, Ritter von Schönerer, its most violent exponent. On the Czech side, too, extremism developed. The Young Czechs disliked the squalid bargaining in the *Reichsrat* and wished to revive the program of state rights by which all Bohemia should become a Czech preserve. The rise of these extreme parties drove Taaffe to seek a compromise with the more moderate national leaders in the *Reichsrat*. In 1890 a committee of Czech and German deputies produced a practical agreement by which provinces with more than one nationality should be divided for administrative and judicial purposes. The struggle for jobs in the bureaucracy, which was the core of the national struggle, was to be settled by creating enough jobs to satisfy all competitors. This settlement, however, was rejected by both Young Czechs and nationalist Germans. The Germans would not surrender Prague, despite their own claim for an exclusively German area, and the Young Czechs would not surrender the unity of Bohemia. In 1891 both Czech and German moderates were routed at the elections for the *Reichsrat*, and in 1893 attempts to divide the judicial system in Bohemia led to Czech riots in Prague and to the proclamation of a state of siege.

Taaffe decided to break the opposition of the middle-class parties by calling in the lower classes. His era had seen the foundation of mass parties. In 1887 Karl Lueger (*q.v.*) had founded the Christian Socialist league, which appealed to the small shopkeepers and clerical peasants; though anti-Semitic and anticapitalist it was loyal to the dynasty and strongly opposed to national disruption. In 1889 Viktor Adler (*q.v.*) had united the scattered Marxists of Austria in the Social Democratic party at the party conference at Hainfeld. Though the Social Democrats used revolutionary phraseology, they too were opposed to national disruption; besides they were mainly concerned, in practice, with improving the conditions of the industrial workers. Their Marxist philosophy made them depreciate the importance of national emancipation, though their own movement was soon divided on national lines. Thus the trade union organizer claimed and secured for himself the national freedom which he denied to his followers.

Taaffe was won for the idea of appealing to the workers and lower middle class by Emil Steinbach, who had become minister of finance in 1889. Francis Joseph acquiesced in the hope (afterward justified) that universal suffrage would make the Social Democrats less revolutionary. On Oct. 10, 1893, a bill was introduced abolishing the complications of electoral law and giving the vote to all adult males. The parties, even the national demagogues, saw their ruin and formed a coalition against it. Moreover Kálnoky also intervened on grounds of foreign policy. Since the fall of Bismarck in 1890 the German government had dropped its restraint in the Balkans and was giving Austria-Hungary firm backing against Russia; Kálnoky could not therefore allow anything which seemed to weaken the Germans in Austria or lessened the impression that the Habsburg monarchy was a German national state. Francis Joseph feared that the *Reichsrat* coalition might

impose upon him a parliamentary ministry. He therefore proposed that if the parliamentary leaders would become ministers on his terms, universal suffrage should be dropped. The terms were accepted, and on Nov. 11, 1893, Taaffe left office.

Badeni.—The new ministry, under Alfred, third prince von Windischgrätz, was ostensibly formed by a coalition of the leading parliamentary parties—the German liberals, the clericalist great landowners and the Poles. They were united only in opposition to universal suffrage. The national struggle had merely been transferred from the *Reichsrat* to the ministry, and each minister defended his national cause. As in the days of Metternich, administration took the place of government. The ministry was torn by ceaseless conflict. The end came in June 1895, when the government fulfilled an old promise of Taaffe and introduced Slovene classes into the grammar school at Cilli (Celje) in Styria. Since the school hitherto had been exclusively German this was regarded as a grave blow at the German cause, and the German liberals resigned. A temporary ministry under Erich, Graf Kielmansegg, lasted till the end of September. Then, on Oct. 2, Kasimir Felix, Graf Badeni (*q.v.*), former governor of Galicia, took office.

Badeni's answer to the franchise question (1896) was to add a fifth layer of constituencies to the curial system, returning 72 members by qualified universal suffrage. Like many others before and after, Badeni was confident that he could settle the conflict between Czechs and Germans. His hands were freed by developments in foreign affairs; the Balkan crisis had died away; and with the fall of Caprivi German policy had again taken on a friendly attitude toward Russia. Moreover in 1895 Kálnoky had overreached himself; to improve his relations with the Vatican, he had tried to interfere with the anticlerical trend in Hungarian legislation and at once had been forced from office by Hungarian protests (May 1895). His successor, the younger Agenor Goluchowski, was a Pole and therefore by no means friendly to Russia by inclination. But since he could not count on either German or British support he was driven to make an agreement with Russia (April 1897) which put the near east "on ice" for an indefinite period. Thus Badeni was free to conciliate the Czechs without fearing the effect on opinion in Germany.

His great stroke was the ordinance of April 5, 1897, which put Czech and German on an equality in Bohemia even for "the inner service"; *i.e.*, for communications within and between government departments. Since the Germans refused to learn Czech (were indeed forbidden to do so by a diet decree of 1868) Badeni's ordinance would give the Czechs a monopoly on government employment. Schönerer thought that his chance had come to disrupt the Habsburg monarchy. His followers obstructed the proceedings of the *Reichsrat*, as the Irish had obstructed those of the British house of commons. Karl Hermann Wolf distinguished himself by throwing an inkpot at the speaker and was removed by the police. German demonstrations followed in Vienna, Salzburg and Graz. Francis Joseph feared that the days of 1848 had come again; on Nov. 28, 1897, Badeni was dismissed.

Körber.—There followed three years of interregnum, when a bewildering succession of ministers attempted to piece together the fragments broken by Badeni. Paul von Gautsch von Frankenthurn (Nov. 1897–March 1898) proposed that Czech and German should be used only in the "mixed" districts of Bohemia; this was rejected by both nationalities. Franz, Graf von Thun-Hohenstein (March 1898–Oct. 1899) tried to force the economic agreement with Hungary over the *Reichsrat* by "emergency decree" (paragraph 14 of the constitutional laws of 1867). A challenge from the Germans brought his resignation. Graf Manfred von Clary-Aldringen (Oct.–Dec. 1899) restored pre-Badeni requirements in Bohemia and so at once provoked Czech rioting and obstruction. Finally Ernst von Körber became prime minister in Jan. 1900. Francis Joseph had long abandoned hope of settling the national question or even of constructing a ministry which should be supported by a majority of the *Reichsrat*; it was enough that there should not be a compact majority against it. The ministers were henceforth bureaucrats, not politicians; and the leading bureaucrat, or prime minister, merely added a certain contact with the *Reichsrat* to his other office duties.

Körber perfected the system by which all necessary legislation was promoted as emergency decree and the *Reichsrat* then kept in a state of division so as not to reject it. The parties were "kept sweet" by local concessions; in return they left government to Körber and his fellow bureaucrats. Körber actually carried the budget of 1902 and the customs agreement with Hungary (Dec. 31, 1902) in a regular parliamentary manner, but he could not repeat his success. The politicians would vote neither for nor against the budget. Körber also introduced old-age and sickness insurance into Austria. In Dec. 1904 his bargainings miscarried and he was driven from office by a combination of parties.

Universal Suffrage.—Gautsch, who took office again in succession to Körber, intended to follow the same cynical path, but events were too much for him. This was the period of the conflict in Hungary between Francis Joseph and the party of independence, which was attacking the common army. To defeat these attacks Francis Joseph appointed a nonparliamentary ministry in Hungary under Géza Fejérváry (June 1905) and then, closing the Hungarian parliament, threatened to introduce universal suffrage (Feb. 1906). Almost simultaneously occurred the first Russian revolution, which for a short time achieved universal suffrage in Russia. Widespread demand for universal suffrage followed in Austria, and Francis Joseph was suddenly converted by the arguments that had been put before him by Taaffe and Steinbach in 1893: universal suffrage would weaken the middle-class nationalist parties, therefore he must have it without delay.

The first bill, produced by Gautsch on Feb. 23, 1906, roused general opposition from the parliamentary politicians, and Gautsch resigned. But imperial and popular pressure combined to beat down parliamentary opposition. After a short ministry under Prince Conrad von Hohenlohe-Schillingsfürst (March–June 1906), Max Wladimir, Freiherr von Beck, another official, became prime minister. He succeeded in carrying the suffrage bill in Dec. 1906. The vote was given to every male of 24, the complicated constituencies were abolished, and instead constituencies were devised so as to give accurate representation to each nationality. The only injustice was in Galicia where the Poles received 20 seats more than their number deserved at the expense of the Ruthenes (Ukrainians). The total membership of the house of representatives was increased from 425 to 516, the Germans now inescapably in a minority with 233 members. The general election of 1907 seemed to confirm the hope that universal suffrage would eclipse the nationalist parties and would substitute a game of *rouge et noir* played on the imperial table. The Christian Socialists were returned as the largest party with 94 members, and the Social Democrats followed close on their heels with 87. Both parties were loyal (*kaisertreu*) despite their supposedly subversive social doctrines. It was a curious irony that the Habsburg monarchy now rested on a Marxist-clericalist coalition.

Beck made the most of his success. He passed the budget in the regular way (for the last time); the backing of the *Reichsrat* enabled him to strike a favourable tariff bargain with Hungary, and he even included parliamentary leaders in his ministry. New difficulties soon arose, and Francis Joseph was impatient for quick results. The Ruthenes agitated with justification against the Poles, and Count Adam Potocki, the governor of Galicia, was assassinated. The Germans obstructed the Bohemian diet, and the Czechs in retaliation obstructed the *Reichsrat*. Beck might have survived these difficulties had he been secure elsewhere; but he was disliked by court circles for his advocacy of "revolution from above," and in 1908 ruined himself by opposing Aehrenthal's foreign policy. He was forced out of office as a result of the Bosnian crisis in Nov. 1908.

The Bosnian Crisis.—Austria-Hungary had enjoyed a breathing space in foreign affairs while Russia was engaged in the far east. This ended when Russia was defeated in the Russo-Japanese War (1904–05). Aloys Lexa von Aehrenthal (*q.v.*), who became foreign minister in Oct. 1906, planned to revive Metternich's conservative partnership with Russia and thus to free Austria-Hungary from German tutelage. He was ignorant of domestic affairs and did not understand that a partition of the Balkans with Russia was barred both by Austria-Hungary's national con-

flicts and by its economic interests which extended into Russia's projected sphere. On the other hand Aehrenthal was pressed from the first to do something to silence the supposed challenge from Serbia, which had broken away from Habsburg hegemony in 1903 and could not be brought to heel either by coercion or conciliation. When a tariff war failed (1906), Aehrenthal offered the Serbs a favourable commercial agreement only to have it rejected both by the *Reichsrat* and by the Hungarian parliament. The situation was made graver by events in Hungary which seemed to be turning Serbia into "the Piedmont of the South Slavs." During the Hungarian constitutional crisis of 1905–06 the Croats, instead of repeating the hostility of 1848, offered to co-operate with the Hungarian party of independence if Croatia in its turn could be freed from Hungarian control. To strengthen their hands the Croat leaders joined with Serb representatives from Dalmatia and parts of Croatia to form the Serbo-Croat coalition. Though this group used South Slav phrases, it was far from being disloyal or disruptive in origin; its only purpose was to ensure that Serbs and Croats within the monarchy were not played off against each other either by the emperor or by the Hungarians. But in the course of 1906 the Hungarian party of independence made up its quarrel with Francis Joseph. It dropped its attacks on the common army and received a free hand to renew its policy of Magyarization against the Slavs and Rumanians in Hungary.

Thus the Serbo-Croat coalition was driven into the arms of independent Serbia by Hungarian intransigence and imperial weakness. Since Francis Joseph would not challenge the privileged Magyar nation, he and his ministers had to pretend that South Slav discontent was caused solely by agitation from Serbia. Aehrenthal proposed to humiliate Serbia by annexing Bosnia and Hercegovina, the Turkish provinces occupied by Austria-Hungary in 1878; the annexation would show that Austria-Hungary was a great power and that Serbia could not hope to liberate South Slav territory. In Sept. 1908 he secured, as he thought, the approval of Count A. P. Izvolski, Russian foreign minister, at a meeting at Buchlau (Buchlov), in exchange for his agreeing to the opening of the straits to Russian ships of war. The two provinces were declared annexed by autograph letters of Oct. 5 and an imperial rescript of Oct. 7. This exploded "the Bosnian crisis." Great Britain and France objected to the opening of the straits and prevented Izvolski from collecting his promised reward. Moreover, Russian opinion cared nothing for the straits and much for the South Slavs; Izvolski therefore had to protest and still more to encourage Serb protests. Thus Russia's backing of Serbia and Serb patronage of the South Slavs within the Habsburg monarchy were both Aehrenthal's doing. Far from solving the South Slav question, Aehrenthal had created it in earnest.

War seemed imminent. Russia was unprepared, however, and France reluctant to support Russia. In March 1909 a German ultimatum compelled Izvolski to abandon his support of Serbia. Aehrenthal could now have had the war against an isolated Serbia which he had originally planned. But even before the German ultimatum he lost his nerve; he at last appreciated the problem which had baffled abler men—what would be achieved by war against Serbia, even if successful? The Habsburg monarchy could not afford to annex more South Slavs; it had too many already. Aehrenthal's turn against war was supported by Francis Joseph, skeptical of the strength of his army, and even by Francis Ferdinand, the heir to the throne, who opposed anything which might benefit the Magyars. Franz Conrad von Hötzendorf, chief of the general staff, remained alone in his advocacy of war. On March 25 Aehrenthal tamely accepted a Serb promise not to protest further. Nothing, however, was done either to conciliate Serbia or to satisfy the South Slavs. Serbian feelers for appeasement (the last in 1913) were rejected. Serbo-Croat coalition within the monarchy was treated as a treasonable conspiracy. Its leaders were sentenced for treason at Zagreb, after a trial so farcical and corrupt that they were at once pardoned by Francis Joseph. Moreover, during the Bosnian crisis, Aehrenthal supplied "proofs" of Serbo-Croat treason to the historian Heinrich Friedjung, who thereupon used them in newspaper articles. The Serbo-Croat leaders took legal action against Friedjung, and in the trial it was shown beyond dispute that the proofs supplied by Aehrenthal were forged. At the meeting of the delegations, T. G. Masaryk (*q.v.*) explicitly accused Aehrenthal of having had them forged in the Austro-Hungarian legation in Belgrade, and Aehrenthal did not attempt to answer the accusation. (It is more than probable, however, that Aehrenthal himself and even Masaryk were victims of an ingenious forger.)

Bienerth and Stürgkh.—The Bosnian crisis exhausted all initiative in the Habsburg monarchy. Beck had advocated "revolution from above" and had been turned out in Nov. 1908; Aehrenthal had aimed at a solution by violence and missed his aim. Henceforth affairs drifted. Richard Bienerth, who succeeded Beck as Austrian prime minister, offered to include Czech and German ministers without portfolio in his cabinet as watchdogs of their respective national interests; the Germans scented in this an admission that Bohemia was Czech and refused to co-operate. Gautsch (prime minister, June–Nov. 1911) also fell foul of the Germans. Karl, Graf von Stürgkh, who succeeded him, played for safety by doing nothing. Even this did not work. In 1913 German obstruction brought the Bohemian diet to a standstill, and Stürgkh suspended the provincial constitution. In March 1914 Ruthene obstruction wrecked the *Reichsrat*, and it too was suspended. Thus the reign of Francis Joseph ended in the "provisional absolutism" with which it had begun. Nor was this all. Since the Hungarians insisted on treating all South Slavs as traitors, the constitution of Croatia was also suspended in 1912 and the Hungarian governor ruled Croatia as dictator. Only the Hungarian parliament remained in existence, and even there István Tisza was engaged in a policy of negation. Recognizing that Hungary could never secure a more favourable settlement than dualism, he was opposed to any change in Hungarian conditions at home or abroad.

Austria-Hungary was equally ineffective in foreign affairs. Every Habsburg statesman had insisted that Austria-Hungary could not allow the dismemberment of the Turkish empire. Yet when the Balkan War broke out in Oct. 1912, Aehrenthal's successor Leopold, Graf Berchtold, did nothing. The conservative alliance with Russia made a ghostly appearance when the Balkan states were warned by the two great empires that they would not be allowed to acquire Turkish territory. The Balkan states ignored the warning, annexed Turkish territory and kept it. In the course of the Balkan Wars (*q.v.*) Austria-Hungary mobilized once and sent an ultimatum to Serbia twice, but was prevented from war by the German refusal to support it. All that Austria-Hungary salvaged from the wreck was Albania, precariously created by the great powers. Despite Albania, the Turkish empire in Europe had vanished. The national principle had triumphed in every frontier of the Habsburg monarchy. To keep going at all, Berchtold had to become a Balkan politician and to boast of his alliance with Bulgaria. Serbia, aggrandized with Ottoman territory, now began to take its role as the Piedmont of the South Slavs more seriously. It was even graver for the Habsburg monarchy that Rumania turned against its alliance with the central powers and went over to friendship with Russia (June 1914). Every neighbour coveted Habsburg territory with national justification. Even Germany tolerated the Habsburg monarchy only so long as it acted as Germany's agent in southeastern Europe. Thus, in view of the deadlock in home affairs Austria-Hungary could arrest national disruption only by a war against the national states, which would in fact make it the dependent and prisoner of Germany, greatest of the national states.

World War I.—Nevertheless Austria-Hungary might have dragged out a long state of suspended animation. It was characteristic, for instance, that the Habsburg monarchy, once the prototype of military empires, now spent less on armaments than any other great power, less even than Italy. By 1914 the real great powers had almost forgotten Austria-Hungary; their conflict of interests had shifted to Turkey in Asia.

On June 28, 1914, Francis Ferdinand (*q.v.*), nephew of Francis Joseph and heir presumptive, was assassinated at Sarajevo. Francis Ferdinand had acquired an inflated reputation as a potential re-

former or even saviour of the monarchy; he was assassinated simply as an alien and unwelcome ruler by a Bosnian Serb. The Austro-Hungarian government possessed no evidence that the Serb government was implicated in the murder, and none was ever found. Still it was hastily decided to force war on the Serbs. Conrad, the chief of staff, had always desired war against somebody; Berchtold's reputation could not stand another ultimatum without a war to follow it; Francis Joseph wished to vindicate the honour of the dynasty, though he had disliked his nephew; even Tisza acquiesced in war against Serbia, after imposing the nonsensical condition that Austria-Hungary should not acquire any Serb territory. Berchtold and his associates did not plan a world war but were resolved on war with Serbia, even if it brought a world war in its train. The ultimatum to Serbia, drafted so as to provoke war, was dispatched on July 23; the Serbian answer was rejected as inadequate, and war was declared on July 28. (*See* WORLD WAR I.)

The Serbs drove back the invading armies and in the autumn of 1914 themselves invaded southern Hungary, while the bulk of the Austro-Hungarian army was engaged against the Russians in Galicia. The Habsburgs were "saved" by German power. Early in 1915 German armies drove the Russians out of Galicia; later in that year German generals conducted a campaign which overran Serbia. For all practical purposes Austria-Hungary had ceased to exist as an independent power and was merely a German satellite, no more independent than Bavaria. This was shown early in 1915 when the Germans sought to buy Italy from entering the war on the entente's side by offers of Austrian territory: the Austrian foreign ministry was not consulted or even informed. Italy declared war on Austria-Hungary on May 23, 1915.

The war had an equally decisive effect on home affairs. Once Austria-Hungary became a military appendage of Germany, the Germans in Austria became again "the people of state." All German parties except the Social Democrats united in the "Easter manifesto" of 1915, which simply restated the Linz program of 1882: Dalmatia should be surrendered to the Italians, Galicia to the Poles, the rest of Austria was to become a German unitary state. Thus the German Austrians had returned to the program of Schmerling; they even dreamed of restoring German supremacy over Hungary. The reverse happened. Hungary controlled the food supply of the monarchy and could dictate terms. In Jan. 1915 Berchtold was dismissed on Tisza's orders; his successor, Baron Stephan Burián von Rajecz, was the first Magyar to become foreign minister since Andrássy and took his orders from Tisza, not from Francis Joseph. The power of Hungary was shown when Germany attempted to repeat with Rumania the maneuver which had failed with Italy and to buy Rumania off with part of Transylvania. Tisza at once imposed a decisive veto; and in 1916 Rumania entered the war on the Allied side (Aug. 27, 1916). The subsequent defeat of Rumania was achieved entirely by German armies.

Yet it would be wrong to suppose that all the nationalities except the Germans and Magyars were actively disloyal. Many Poles hoped for a restored Poland under a Habsburg archduke, and Jozef Pilsudski, the Polish leader, co-operated with the Austro-Hungarian forces. The Croats, Slovenes and Slovaks, once allies of the dynasty in 1848, vied with each other in loyalty and still hoped for an empire "above the nationalities." The Croats fought willingly against the Serbs and enthusiastically against the Italians. The only nationality which recognized that it had everything to lose by a German victory was the Czech; and even Czech opposition was negative. In Dec. 1914 Masaryk left Bohemia for western Europe in order to win the Allies for his program of Czechoslovak independence; but he knew that he could succeed only in the event of a long war.

Francis Joseph sustained the fabric of administration until his death (Nov. 21, 1916). Even the assassination of Sturgkh (Oct 1916) by Friedrich Adler, a pacifist Socialist, only led to the recall of Körber to the prime ministry. Charles I (*q.v.*) grandnephew of Francis Joseph, succeeded to the throne and tried to break the deadlock at home and abroad. Convinced that the war was lost, he opened secret negotiations with the entente powers in the spring of 1917; but, though he was ready enough to consent to the acquisition of Alsace-Lorraine by France, he refused to surrender any territory to Italy and even insisted on Habsburg hegemony over Serbia. Charles tried to avoid being crowned king of Hungary, so as to be able to impose changes in favour of the national minorities. Tisza brought him to heel by threatening to stop the food supplies of Vienna. Tisza was driven to resign by Charles's insistence on suffrage reform in Hungary, but his resignation produced no change. After a brief interval Tisza was succeeded by Alexander Wekerle, a Magyarized German who was equally opposed to an extension of the franchise.

In Dec. 1916 Charles got rid of Körber as Austrian prime minister and replaced him by a Bohemian noble, Graf Heinrich Clam-Martinic. Czech leaders, sentenced for treason in 1915, were amnestied, and the *Reichsrat* was summoned for May 30, 1917. The Czechs now demanded the union of all Czechs and Slovaks "in a single Bohemian state." The South Slav deputies (principally Slovenes with a few Croats from Dalmatia) demanded a union of all South Slavs within the monarchy. These demands, though theoretically compatible with the survival of the Habsburg monarchy, challenged German supremacy in Austria and, still graver, the integrity of Great Hungary. Since Germans and Magyars held all the real power, Charles could make no concessions until Germany had been defeated in war; and then it would be too late. Charles could only offer a "ministry of the nationalities" under Joseph Redlich; its only function would have been to deceive the nationalities, and the offer was refused. Clam-Martinic threw up his post in despair, and administration passed to Ernst von Seidler (June 1917), a bureaucratic prime minister of the old type.

Austria-Hungary was now more than ever dependent on Germany. Ottokar, Graf Czernin (foreign minister, Dec. 1916–April 1918), continued secret negotiations with the Allies but could never offer the separate peace which was all that they wanted. The defeat of the Italians at Caporetto (Oct. 1917) failed to knock Italy out of the war. Czernin attended the peace negotiations with Russia at Brest-Litovsk and signed the treaty (March 3, 1918); his only concern was to secure Ukrainian wheat and even in this he was not successful. In April 1918 Clemenceau revealed the secret negotiations with Charles in the previous year, and Czernin was dismissed as a scapegoat on German orders. Charles himself had to visit German headquarters at Spa and surrender all independent initiative. Burián was restored as foreign minister on German and Hungarian instructions. He too made gestures toward peace but trembled before the German veto even when the German armies were defeated in Aug. 1918.

Meanwhile the Czech deputies to the *Reichsrat* and in the three "Bohemian" diets issued a manifesto on Jan. 6, 1918, demanding a sovereign state "within the historic boundaries of the Bohemian lands and of Slovakia" (at this revolutionary moment it did not matter that Slovakia had never existed and had no historic boundaries). In Aug. 1918 the Allies recognized the Czechoslovaks as "an allied nation," with Masaryk and his national council "as present trustee of the future Czechoslovak government." On the military side Conrad launched an offensive on the Piave (June 15, 1918) which altogether miscarried; and he was dismissed. A new prime minister, Max, Freiherr Hussarek (July 17, 1918), abandoned even words of conciliation for the Czechs and instead offered the Germans the administrative partition of Bohemia.

Disaster came swiftly in September when the Bulgarian front collapsed. On Oct. 4, Burián dispatched a peace note to U.S. Pres. Woodrow Wilson, accepting his Fourteen Points; Wilson replied on Oct. 21 that he could no longer accept "autonomy" as the basis of peace. On Oct. 16 Charles issued a manifesto promising to transform Austria into a federal state; even this scheme was made worthless by the proviso that it would not infringe the territorial integrity of "Great Hungary." Then the new foreign minister, Gyula Andrássy, son of the founder of dualism, in an effort to secure recognition of some dynastic fragment, agreed (Oct. 27) to accept the independence of Czechoslovakia and of the new South Slav state. This note never received a reply. On Oct. 27 also Heinrich Lammasch, a reputed expert in

national problems, was appointed prime minister to preside over the dissolution of the Habsburg state; no one would negotiate with him even for this purpose.

The Poles had already declared their independence at Warsaw on Oct. 7. On Oct. 28 the Czechoslovak republic was proclaimed in Prague. The Slovaks had only reached the point of demanding "autonomy" within Hungary; though still negotiating with Budapest, they accepted the new Czechoslovak state on Oct. 29. The Slovenes and Croats found themselves defenseless against the Italians and became South Slavs as the lesser evil: the Yugoslav state was proclaimed in Zagreb on Oct. 29. The master nations also abandoned the dynasty. On Oct. 31 a democratic government under Mihály, Count Károlyi, was formed in Budapest; and three days later Károlyi announced the end of dualism and the establishment of Hungary as an independent state. The German Austrians had opposed the program of national self-determination so long as it operated against them; they now tried to invoke it against the Czechs for the sake of the Germans in Bohemia. On Oct. 30 the German members of the *Reichsrat* turned themselves into a German national assembly and proclaimed the state of "German-Austria," a state without boundaries or definition but with a government composed of Socialists, whereby the Germans too hoped to transform themselves into an "oppressed people."

Imperial authority had collapsed. On Nov. 1 Károlyi ordered all Hungarian troops to return home; the troops of other nationalities needed no orders. On Nov. 3 the Austro-Hungarian high command, negotiating on behalf of an empire which no longer existed, concluded an armistice with the Italians. The army thereupon disintegrated. The Lammasch government made some attempt to secure the emperor's personal safety but failed to accomplish even this and vanished. Charles renounced all share in the government of German-Austria on Nov. 11, in that of Hungary on Nov. 13. He refused to abdicate and carried his empty titles into exile. A republic of German-Austria was proclaimed on Nov. 12 and a republic of Hungary on Nov. 16. For the history of the Austrian republic *see* AUSTRIA: *History*. (A. J. P. T.)

AUSTRIA, LOWER (NIEDERÖSTERREICH), a *Bundesland* (federal state) of the Republic of Austria. Area 7,402 sq.mi. (19,170 sq.km.).

Physical Geography.—Lying astride the Danube from the mouth of the Enns to that of the March and to the Leitha mountains, it shares in four of Austria's physical regions: the Granite plateau, the Alps, the northern Alpine foreland and the Eastern lowland.

The Lower Austrian part of the Granite plateau, the Waldviertel ("forest quarter"), extends to the Manhartsberg range and across the Danube and is a dissected or undulating plateau with deeply incised rivers. In the west the climate is cold and damp while farther east mean annual temperatures rise and rainfall decreases to as little as 24 in. The soils follow a similar pattern, forest covers up to 60% in the west while in the east there is extensive arable land. Its share of the Eastern lowland, popularly known as the Weinviertel ("wine quarter"), is hilly country with extensive loess cover and favourable climate. Wheat, maize (corn) and sugar beet fields are interspersed with market gardens, orchards and vineyards. The southern Vienna basin south of the Danube (the Vienna bay) structurally belongs to the Alps. Bordered by the easternmost ranges (*e.g.*, the Leitha mountains) of the Central Alps to the east and the fault scarp of the limestone mountains to the west, its landscape and climate resemble that of the northern Vienna basin though its gravels support only pinewoods and heaths. Along the southwest-northeast faultline thermal springs have given rise to spas (*e.g.*, Baden).

The Alpine area includes parts of the Central Alps to the south and Limestone and Flysch Alps to the north of the Semmering (*q.v.*) pass. The Central Alps reach 5,702 ft. in the wooded Wechsel mountains. The Bucklige Welt to the east is considerably lower, and forests alternate with grassland and some fields. The Limestone Alps rise to more than 6,500 ft. On their highest levels are barren karst (*q.v.*) surfaces, and the karst springs at the foot of Raxalpe and Schneeberg supply Vienna with part of its water. Woodland predominates at lower altitudes and farther north as in the sandstone Flysch Alps which reach their greatest extent and terminate in the Vienna woods. There beech replaces the conifers of the Limestone Alps. The climate of the Alpine part varies greatly, depending on altitude and exposure. The importance of the Alpine foreland region is far greater than its size would indicate. A hilly, well-watered area 650 to 1,330 ft. in altitude, it is widely covered by loess, supporting predominantly arable cultivation.

History.—Human settlement began in the Paleolithic period

The areas which attracted prehistoric man were the Wachau (Danube gorge), the area around Horn, the Alpine foreland and the Vienna bay along the thermal line.

The name Austria Inferior was coined when King Otakar of Bohemia, who had taken possession of Austria in 1251, divided the duchy for administrative purposes along the river Enns. Although the official name of this part remained until 1918 Österreich unter der Enns, it was popularly called Niederösterreich. (The latter title was used by the emperor Maximilian, and subsequently, to denote Upper and Lower Austria, Styria, Carinthia, Carniola and the adjoining coastland.) The definite administrative division between Upper and Lower Austria took place about 1450. There were no permanent changes in the boundaries of Lower Austria until after World War I when an area near Gmünd was ceded to Czechoslovakia. Lower Austria became a *Bundesland* in 1918 and in 1920 lost Vienna except as the seat of its administration. During the *Anschluss* period (1938–45) it was the *Reichsgau Niederdonau* of greater Germany, extending farther north and east and with Krems as its capital, but losing land to Vienna. It was again a *Bundesland* in 1945 with its former boundaries and in 1954 under the district reorganization law recovered most of the area (309 sq.mi.) which had gone to Vienna. (*See* also AUSTRIA: *History;* AUSTRIA, EMPIRE OF.)

Population.—The population in 1961 was 1,374,012, a decrease since 1934 in common with all *Bundesländer* which formed part of the Soviet zone of occupation. The density was 185.6 to the sq.mi. Ethnically, Lower Austria is purely German, the dialect spoken belonging to the Bavarian group. Most of the people are Roman Catholic (included in the dioceses of St. Pölten and Vienna), but there are small Protestant communities. About half of all Austrian towns are in Lower Austria. The principal (pop. 1961) are: St. Pölten (40,112), Wiener Neustadt (*q.v.;* 33,845), Baden (*q.v.;* 22,484), Krems an der Donau (21,046), Amstetten (12,086), Stockerau (11,853), Neunkirchen (10,027). One-fifth of the people live in places of more than 5,000 inhabitants. The number of old townships with few inhabitants include the famous Dürnstein in the Wachau (where Richard Coeur de Lion was imprisoned) with 600 and Hardegg on the Thaya with 300. Rural settlement is characterized mainly by villages of the regular "colonial" types except for the Alpine foreland and Alps where dispersed hamlets and isolated farms prevail. Characteristic houses are the square farmstead in the western Alpine foreland, multiple farmsteads in the southern Alpine part and single file farmsteads in the east.

Administration and Social Conditions.—Matters not reserved by the constitution for the federal government are dealt with by the *Bundesland* government, consisting of the governor and six other members elected by and responsible to the provincial diet (*Landtag*), which has 56 members elected for five years by popular vote. The *Landtag* is a legislative body but the acts it passes must be approved by the federal government. In the *Bundesrat* (upper house of the federal diet) Lower Austria has ten votes. After 1954 it was divided into 21 administrative districts. Local government is in the hands of burgomasters and commune councils elected by popular vote.

The prevalence of small farms of less than 5 ha. (12 ac.) (only 13% are larger than 20 ha.), with extreme fragmentation of holdings, has a great bearing on social conditions, causing the excessive use of family labour and comparatively low living standards. The conditions of the urban and industrial population are also inferior to those of the western *Bundesländer*, attributed partly to earlier industrialization but more to war damage, dismantling and slow recovery after Soviet occupation.

The Economy.—Agriculture and forestry supported (in 1951) about 47% of the working population. Nearly 60% of the land is used for agriculture (almost three-quarters is arable) and more than one-third is forested. The main farming areas are the Eastern lowland and the Alpine foreland. Grain (wheat, rye, maize, barley for brewing) takes first place but root crops (potatoes, sugar beet and fodder beet) follow closely. Viticulture in the Weinviertel, the Wachau, the southern bank of the Danube east of Vienna and the slopes of the Vienna bay, both in area and production, amounts to more than 60% of the Austrian total. Fruit, associated with mixed farming, is grown mostly in those areas and in the Alpine foreland, especially plums, cherries and apricots. There is market gardening around Vienna. Lower Austria also leads in livestock. Except in the higher parts cattle are stall-fed. Large tracts of forest, especially in the Alps, are state owned and highly productive in timber (nearly 2,000,000 cu.m. annually).

Oil and natural gas production in the northern Vienna basin is the chief extractive industry, with a pipeline to Vienna and a refinery of 1,600,000 tons capacity at Schwechat. There is the important Ybbs-Persenbeug hydroelectric power station on the Danube. Mesozoic coal is mined in the Limestone Alps and Tertiary brown coal near Wiener Neustadt and St. Pölten; gypsum near Grünbach and graphite in the Wachau. There are brick and ceramics industries, and limestone quarrying for the largest Austrian cement plant at Mannersdorf. The deposits of siliceous earth northeast of Krems are unique.

Industries include food processing, sugar refining and brewing, timber (about 1,000 sawmills) paper and cellulose, and the heavy metal industry, mainly in the Alpine valleys, fed by Styrian iron ore. Textiles are concentrated around Baden, at St. Pölten and in the northern Waldviertel, which also has an old-established glass industry, and chemicals at St. Pölten, Korneuburg and south of Vienna; the Semperit rubber plants at Traiskirchen and Wimpassing are the *Bundesland's* largest industrial concern. Wiener Neustadt has a small aircraft factory.

Communications.—Trade routes have crossed this region since earliest times, for Vienna is the meeting point of many natural routeways: from the North sea, the north, and the northeast, via the Moravian gate; from the Adriatic by the Semmering pass. The prehistoric "amber" route crossed the Danube east of Vienna and a Roman road along the Danube was met at Vindobona (Vienna) and Carnuntum (Petronell) by one from the south. These routes were used by the first railways: the Nordbahn (to Cracow, 1837–39); the Südbahn, which crossed the Semmering (1848–54) and was the first mountain railway in the world; the Westbahn along the Danube valley. Roads also centre on the Vienna area, including the motorway from Salzburg and the planned Vienna-Graz motorway. Two-thirds of the Danube in Austria lies in Lower Austria, including the beautiful Wachau, providing goods and passenger transport. There is a cog railway to the Schneeberg and a funicular cable line to the Raxalpe. Vienna's airport of Schwechat is the largest and most important in Austria. *See* also AUSTRIA.

AUSTRIA, UPPER (OBERÖSTERREICH), a *Bundesland* (federal state) of the Republic of Austria. Area 4,625 sq.mi. (11,978 sq.km.).

Physical Geography.—Lying astride the Danube from the Inn to the Enns rivers, Upper Austria includes part of three of Austria's physical regions: the Granite plateau, the Alps and the northern Alpine foreland. Its Granite plateau area roughly ends at the Danube and is called Mühlviertel ("Muhl district") after its main river. Its surface is undulating and slopes gently from northwest to southeast. Because of altitude and exposure to the westerlies its climate is raw and damp except for the sheltered and fertile valley of Freistadt. The soil is generally thin and poor and there is extensive forest with grassland at lower altitudes. The Alpine area, comprising limestone mountains and the Flysch (sandstone) foothills includes most of the Salzkammergut (*q.v.*) with its many lakes (Hallstatt-, Wolfgang-, Mond-, Atter- and Traunsee). At heights of 2,000 m. (6,600 ft.) the surfaces

are barren; below are extensive forests, and in the valleys meadow and some arable land. Although long settled because of salt resources there are only three towns of any size, Gmunden, Ebensee and Bad Ischl. Economically the most important part of Upper Austria is its share of the Alpine foreland. Loess cover at the higher terraces yields a fertile soil, but on the gravel sheets there is much woodland (*e.g., Weilhartforst*). In the centre are the forested hills of the Hausruck and Kobernauser Wald with deposits of brown coal (lignite). Climatically this is the most favoured region.

History.—The most important prehistoric sites were the late Neolithic pile dwellings of the Mondsee and the settlement at Hallstatt (*q.v.*), which owed its importance to the presence of salt. In 1192 the Traungau (the nucleus of present Upper Austria) became an appendix to the duchy of Austria, and as a result the 10th-century name Ostarichi ("eastern region") was applied also to areas west of the Enns. The name Austria Superior was coined when King Otakar of Bohemia, who had taken possession of Austria in 1251, divided the duchy for administrative purposes along the river Enns. Although the official name of this part remained until 1918 Österreich ober der Enns, it was popularly called Oberösterreich. The definite division of Upper from Lower Austria took place around 1450, and in 1490 Linz became its capital (following Enns, Steyr and Wels). During the *Anschluss* (1938–45) Upper Austria became the larger *Reichsgau Oberdonau*, afterward reverting to a *Bundesland*. (*See* AUSTRIA, EMPIRE OF.)

Population.—The population in 1961 was 1,131,623, and the density 244.6 per sq.mi., the highest for all *Bundesländer* except Vienna. The increase was due to industrialization and the influx of more than 100,000 refugees. Ethnically the people are German, a Bavarian dialect being spoken, and mostly Roman Catholic (the Linz diocese is virtually coincident with Upper Austria). A small number (less than 7%) are Protestants.

The principal towns (pop. 1961) of Upper Austria are: Linz (195,978), Wels (41,060), Steyr (38,306), Bad Ischl (12,703), Gmunden (12,518), Braunau am Inn (14,449), Ebensee (9,602), Ried im Innkreis (9,471), Vöcklabruck (9,353), Enns (8,919). Rural settlement, apart from the few large villages, consists of hamlets and isolated farms. Traditional farmhouse types are the single unit farmstead to the west and the multiple farmstead to the east of the Traun river. The most impressive, the *Vierkanter* ("square farmstead"), is found mainly in the Alpine foreland east of the Traun.

Administration and Social Conditions.—Matters not reserved by the constitution for the federal government are dealt with by the *Bundesland* government, consisting of the governor and eight ministers elected by and responsible to the *Landtag* (diet) which is elected for six years by popular vote and has 48 members. The *Landtag* is a legislative body but its acts must receive the approval of the federal government. In the *Bundesrat* (upper house of the federal diet) Upper Austria has seven votes. There are 17 administrative districts (*Bezirke*) of which two, Linz and Steyr, are cities. Local government is the responsibility of burgomasters and town and commune councils elected by popular vote.

The farmers, especially in the Alpine foreland, are more prosperous than those elsewhere in Austria since more than 50% of all farms are of medium size, from 5 to 100 ha. (12 to 250 ac.). Industrialization has not caused serious overcrowding and refugees have been absorbed steadily.

The Economy.—Farming uses 56% of the land and forestry one-third. Most of the grain (wheat and rye) is grown in the Alpine foreland, also sugar beet, especially in the east. More than half of the agricultural land is grass, mainly in the higher regions, though the most intensive stock farming is in the Alpine foreland, based on fodder crops. Fruit cultivation is associated with mixed farming and the bulk of apples and pears are turned into cider on the farms. Large tracts of forest, especially in the Alps, are state owned and production of timber exceeds 1,000,000 cu.m. annually.

Hunting is strictly controlled and licences provide considerable income. The game consists of hares, roe and red deer and chamois. Fishing comprises nearly two-thirds of all Austrian fishing rights and nearly half the breeding stations, mostly trout.

There is salt mining at Bad Ischl and Hallstatt, and a large evaporation plant at Ebensee, combined with a chemical industry; granite quarrying on the lower Inn and the Danube; limestone quarries for cement and brickworks; the important Eternit (asbestos-cement) plant at Vöcklabruck; and brown coal mines in the Hausruck and farther west (a by-product is china clay). Upper Austria leads in major electric power stations. After 1959 oil wells near Ried were in production. Industries include dairying, food processing, sugar refining, brewing, the making of agricultural machinery, tanning (large works at Mattighofen) and sawmilling (with a timber industry and paper and cellulose plants). Dating from the *Anschluss* period are the artificial fibre yarn plant at Lenzing; the aluminum plant at Ranshofen; and the iron and steel works and nitrogen (chemical) plant at Linz, which rely on Styrian ore and imported coal. Linz has become Austria's foremost industrial town; Steyr is an industrial centre with bicycle and vehicle manufacture. The making of glass costume jewelry, introduced after 1945 from Czechoslovakia, centres on Steyr.

Trade and communications have been important since the salt trade of the Early Iron Age. Ovilava (Wels) was the junction of two Roman roads. During the middle ages the rivers were used for the transport of timber, salt and iron ore, but only the Danube has retained this role, Linz being the largest Austrian river port, with a customs-free zone. The first railway in middle Europe (opened in 1832 and horse-drawn) linked Linz with Budejovice in Bohemia. Now Austria's chief line, the Westbahn, is joined at Wels by the line from Ostend and at Linz meets the Pyhrnbahn from the south and the line from Berlin and Prague. The Salzburg-Vienna motorway passes south of Linz. Air traffic at Linz airport is of minor importance. *See* also AUSTRIA.

AUSTRIAN LITERATURE.

AUSTRIAN LITERATURE. The literature of Austria is beyond a certain point inseparable from German literature as a whole. A common language has led to interaction and to a degree of common development; and the article on GERMAN LITERATURE therefore will be found to cover much ground where Austrian writers played an important part. The work of individual writers is also considered more fully in articles under their names. The scope of the present article, therefore, is limited to showing the particular development and special characteristics of Austrian literature—characteristics which grew up through such factors as the country's outlying position, the special place which the Habsburg provinces occupied in the empire, and the success in Austria of the Counter-Reformation which, from the end of the 16th century, divided the country from much of Germany, making it the centre of a baroque culture peculiar to itself. The various territorial and local characters and traditions, notably the temperament and mentality of the Viennese, have also played their part in creating an Austrian literature.

The literature of Austria came into existence at the point where Celtic, Roman and Germanic civilizations met. under the duchy it followed the changes of the Habsburg fortunes, returning under the republic to the country's original boundaries without ever losing entirely the stamp of the regions which contributed to it.

The Duchy.—The country grew out of a little march county on the Danube and first became spiritually aware of itself in a monastic literature belonging to the lands of the Eastern Alps. Biblical material was generally chosen and adapted to the style of the minstrels. In the Danube valley, at least around Melk, this literature had apparently a real public. This is shown by the first individually distinct poets we know of: *c.* 1120 the anchoress Frau Ava, with her deeply personal presentation of the Redemption story; *c.* 1130 Adelbracht with his *Johann Baptista*; *c.* 1150 Priest Arnold with his poem on the Holy Spirit; *c.* 1160 the lay brother Heinrich von Melk with his satirical lays.

After 1156 the duke was a sovereign prince and the first independent ruler in the Holy Roman empire. The new court at Vienna was artistically ambitious. The poem of chivalry was in Austria a native growth with roots among the people; it dates from *c.* 1150 with Dietmar von Aist and the Kürenberger. About 1190 Reinmar von Hagenau (*q.v.*) became court poet to the dukes of Austria, taking the popular songs of chivalry that belonged to the country and building from them his splendid flowing rhythms and his complaints of unhappy love. Walther von der Vogelweide (*q.v.*) was Reinmar's pupil in Vienna *c.* 1185. He ennobled Austrian popular poetry by grafting on to it Reinmar's new style. The most beautiful of his love poems form a cycle of their own, apparently inspired by a simple girl, who, if we understand Walther correctly, brought him a late happiness. It is the finest lyric collection of medieval Germany. But Walther was also the literary "great power" of the Hohenstaufen empire. He exerted this power through his political comment and as traveling minstrel. He had to a remarkable degree the gift of the right word at the right moment. His followers in Austria and also in Tirol formed a whole school of their own. The poetical diaries of Ulrich von Lichtenstein, the country dance songs of Neidhart von Reuental, the poems of Tannhäuser (*q.v.*), with their licence all alike lay their stress on lyricism.

Austrian poetry reached equal stature in the epic, especially in the *Nibelungenlied* (*q.v.*) which reached its final perfection at the hands of an Austrian minstrel. An abundance of related works grouped themselves in the Alpine lands around this wonderful poem: *Ortnit*, *Wolfdietrich*, the *Gudrun* (*qq.v.*), *Laurin*, *Alpharts Tod*, *Dietrichs Flucht*, *Rabenschlacht*, *Biterolf* and *Rosengarten*.

This was the flowering under the Babenberg dukes. At the coming of the Habsburgs there remained, with the declining middle ages, only a barren harvest: jest books, *Novellen*, rhymed commentaries on affairs of the time, the rough humour of the *Neidhartspiel*, written around the poet and folk hero Neidhart von Reuental. In Tirol alone at the turn of the period, Oswald von Wolkenstein (1367–1445) achieved distinction, returning to his Eisack valley after adventurous wanderings and dying there in 1445, the first modern to express himself in lyric.

The Habsburg Empire.—By marriage, inheritance and diplomacy the house of Habsburg was able, after the setbacks of the middle of the 15th century, to acquire first the German imperial throne, then the Burgundian inheritance, then the Spanish lands—the old world and the new, and finally—the dream of centuries—the territories that touched their own, the kingdoms of Bohemia and Hungary. In this wide empire with its vibrating frontiers the duchy, and with it Vienna, was the point of rest. The imperial chancellery migrated in 1438 from the Prague of the Luxembourg dynasty to the Vienna of the Habsburgs, bringing with it a double heritage: the German literary language, which was built up in Prague largely from middle German components; and the humanist disposition and care for style. Through the literary models it provided and the work of its officials, the chancellery became the nursery of early Viennese humanism. The written language which was now developing took on in Vienna Austrian colouring, while humanism gained a recognized leader in Aeneas Silvius Piccolomini, later Pope Pius II (*q.v.*). The emperor Maximilian I, himself a writer (*Weisskunig*, *c.* 1514, publ. 1775; *Teuerdank*, 1517), made Vienna, through chancellery and university, the leading humanist city in Germany. He was the creator of European Austria in both its material extent and its mental attitude. He was helped by Conradus Celtis (*q.v.*), Johannes Spiessheimer (1443–1529) and Joachim von Watt (1484–1551).

Vienna only acquired a theatre after the Renaissance with the *Kaiserspiele*, or court plays, of Conradus Celtis and the *Klosterspiele*, or monastery plays, of the abbot of the *Schottenkloster* Benedictus Chelidonicus (*c.* 1500). The German plays of the schoolmaster Wolfgang Schmeltzl (*c.* 1500–*c.* 1557) were also first performed in the *Schottenkloster*. The coming of the Jesuits gave a new turn to Austrian ideas. From 1554 onward they created out of the dynastic alliance of Austria and Spain a community of religious conviction and mental inclination. They immediately began to perform plays in their school: first Terence, Plautus, the usual school plays and finally their own considerable repertoire. Side by side with this the Italian opera developed, spacious, colourful and especially patronized by the emperors. The Austrian theatre took its baroque stamp from Jesuit Vienna and from the then independent archbishopric of Salzburg; and the Viennese baroque theatre was one of the artistic triumphs of Europe. Not one of the great cities had ever striven to create, as did Vienna, the art of a whole people for the people in their spiritual and physical entirety, though not in the vernacular but in Latin and Italian.

The individual regions flourished too, each in its own way. Tirol had its own courts from time to time. From 1430 there was an abundance of sacred and secular drama, especially in Stezing at the foot of the Brenner where Vigil Raber (d. 1552) was collecting and rewriting the plays of the people. About 1570 Archduke Ferdinand of Tirol led a real poets' court. His court preacher was the spellbinding Johannes Nas; the Jesuits performed plays, while the Capuchin Laurentius von Schnüffis, from being theatrical producer to a duke, became the mystical lyricist of the soul (*Philotheus*, 1678). Salzburg had a life of its own, shining through the humanist Paul von Hofhaimer (1459–1537), who set its tone, through the theatre of the archbishop's court and through the Benedictine university founded in 1620. In Upper Austria the burgess in the little town, the monk in his monastery and the nobleman on his estate were all writing. Styria had the flourishing *Meistergesang* and a wide range of artistic interest in the great monasteries such as Kremsmünster where for example Simon Rettenbacher (1634–1706) was writing religious plays. Christoph von Schallenberg (1561–97), Wolfgang Helmhard von Hohberg (1612–88) and Katharina von Greiffenberg (1633–94), poets who belonged to the nobility, were Protestants. So was the prolific storyteller Johann Beer (1655–1700). The Protestant nobility of Lower Austria occupied itself with the translation of Romance poetry. It was the emperor Ferdinand II, sometime ruler of Styria, who had English actors at his Graz court, who decided the battle against the Reformation, first in Styria and then in all his other lands. The voice of the triumphing church was uplifted in Vienna by Abraham a Sancta Clara (1644–1709), the Habsburg court preacher and master of baroque German prose.

The Austrian Empire From 1740 to 1918.—The last empress of Habsburg blood, Maria Theresa, turned decisively toward the German problems of her lands in order to assert her position in the empire. Her reforms and those of her son Joseph II served the revival of Austria's German language and culture. This is true particularly of the theatre. From 1709 there was a settled theatre at the Kärntnertor for the traveling players. In 1741 the empress added to it the tennis court near the *Burg*, or castle. Joseph II issued a new edict in 1776 after which the Burgtheater began its rise, while alongside it the popular stage or *Volksbühnen* developed. At this time the poet's play took precedence over the actor's play, Vienna becoming once more the first city in the kingdom for drama. The Burgtheater had its heyday under Josef Schreyvogel (1768–1832) and Heinrich Laube (*q.v.*), receiving in the middle of the 19th century its fitting poets in Eduard von Bauernfeld (*q.v.*) for comedy and Franz Grillparzer (*q.v.*) for tragedy. At the same time the popular stage achieved stature through the fairy tale plays of Ferdinand Raimund (1790–1836), the popular pieces of Johann Nestroy (*q.v.*) and the peasant drama of Ludwig Anzengruber (*q.v.*). During the first half of the century Austrian literature extended its influence to parts of the world where the empire had a stake. Joseph von Hammer-Purgstall (*q.v.*), a great interpreter, made the east fashionable in literature. Jakob Philipp Fallmerayer (*q.v.*) turned the eyes of the west toward Byzantium and its heir, Russia. Anton Prokesch (1795–1876), an influential diplomat in Turkey, fascinated through his descriptions of the near east. Charles Sealsfield (pseudonym of Karl Postl; 1793–1864) caught the imagination of the United States with novels in English and German. At the same period, in a great series of poets, the empire displayed itself in all its fullness: as seen by the soldier, with Friedrich von Schwarzenberg (1800–70); through the painter's eye with Adalbert Stifter (*q.v.*); through the strange and bizarre with Ferdinand von Saar (1833–1906); through the heart of the mistress of an estate with Marie Ebner von Eschen-

bach (*q.v.*). Here too is the Austrian countryside clear as on the day of its creation: Upper Austria in the deeply felt dialect of Franz Stelzhamer (1802–74); Tirol in Hermann von Gilm (1812–64) and Adolf Pichler (1819–1900) as well as in the ancient and indestructible Tirolean peasant play, found again with Franz Kranewitter (1860–1938) and Karl Schonherr (*q.v.*); Styria at the same period in its inimitable storyteller Peter Rosegger (*q.v.*).

Vienna itself was more than ever the leader at the turn of the century. The chief development was the entry of the working class into intellectual life and the creation of a working-class poetry. Alfons Petzold (1882–1923) found a modern and more elevated style for this poetry. Siegfried Lipiner (1856–1911), Richard von Kralik (1852–1934) and Hermann Bahr (1863–1934) were the three most stimulating forces in the city, united in the determination to make Austria the cynosure of Europe. The city's richly varied flow of creation developed, presenting the tragic transformation of men through machines with Emil Ertl (1860–1935); the sacrifice of faith and country with Enrica Handel-Mazzetti (*q.v.*); the Vienna of the elegant idler with Arthur Schnitzler (*q.v.*); a stylish recreation of creative people with Stefan Zweig (*q.v.*); quiet happiness of heart in the verses of Franz Karl Ginzkey (1871–1963); and the elevated style of nearly every form with Richard von Schaukal (1874–1942). The crown of the epoch was the librettos of Hugo von Hofmannsthal (*q.v.*) which recaptured the spirit of baroque Austria. Many of these poets, among them Rainer Maria Rilke, Franz Werfel (*qq.v.*), Georg Trakl (1887–1914) and Rudolf Kassner (1873–1959) were of Sudeten German origin and had behind them more than five centuries of a shared tradition.

The Republic After World War II.—The common life of the empire was broken not in 1918 but in 1945 when Hungary and Bohemia finally broke away from their historic bond. It was only then that Austria really found itself once more within its original boundaries. But Austria had to begin life anew, and it was not possible to predict whether its literature would develop as it promised to do. It is an advantage that the characters of the various regions are well-recognized. After World War II Hans Sterneder, Maria Grengg, Rudolf Henz, Friedrich Sacher and August Stöger were writing in the Danube valley. Salzburg was represented by Karl Heinrich Waggerl and Georg Rendl. In Carinthia were Johannes Lindner, Josef Friedrich Perkonig and Wilhelmine Wieser, as well as Robert Musil (*q.v.*) with his novel of Austria, *Der Mann ohne Eigenschaften*. Tirol displayed its multicoloured facets in the work of Josef Weingartner, Josef Leitgeb, Maria Rubatscher, Kurt Ziesel, Franz Tumler and Alma Holgersen. The Voralberg expressed itself in dialogue through Armin Diem and in powerful epic through Gertrud Fussenegger-Dorn. Hans Kloepfer, Julius Zerzer, Bruno Ertler and Paula Grogger spoke for Styria.

Viennese poetry achieved style after 1918 with Otto Stoessl, Alexander Lernet-Holenia and Josef Weinheber. Austrian drama held its direction without losing touch with the movements of the time. Its playwrights were Anton Wildgans (*q.v.*), Felix Braun, Franz Theodor Csokor, Richard Billinger, Josef Wenter, Friedrich Schreyvogl and the indisputable master Max Mell. Prominent voices in Austria after World War II were Heimito von Doderer, Fritz Habeck, Rudolf Bayr, Fritz Hochwälder and Christine Busta. The widest in range among them was Erich Landgrebe.

AUSTRIAN SUCCESSION, WAR OF THE (1740–1748). In 18th-century Europe the failure of the male line in a ruling dynasty was always apt to lead to war, and it did so in 1740 when the head of the house of Habsburg (*q.v.*), who was also the Holy Roman emperor Charles VI, died without leaving a son. In 1713, before any children had been born to him, Charles had issued a pragmatic sanction (*q.v.*), or fundamental law, regulating the succession in the Habsburg dominions. These, by 1740, consisted of the so-called hereditary lands of Austria, Hungary and Bohemia and of various provinces (the southern Netherlands, the grand duchy of Tuscany, the duchy of Milan and other territories in the plain of Lombardy) which had been more recently acquired and were treated as colonies or dependencies. Between 1720 and 1723 Charles had prevailed on the estates, or representative assemblies, in the hereditary lands to agree to the pragmatic sanction. Later (when it had become clear that his inheritance would descend to his daughter Maria Theresa) he had been at great pains to get his provision accepted by the various principalities in the empire and by the interested powers of Europe. All in the end had accepted them apart from the elector of Bavaria, Charles Albert, who disputed Maria Theresa's claim but lacked the power to oppose it unaided.

Charles VI, however, had made no provision for the succession to the imperial dignity which, though elective, had been held by the head of the house of Habsburg since the 15th century. It carried no powers of coercion, but it was a source of considerable prestige and moral authority, particularly among the small and middling states, which saw in the emperor the defender of Christendom against the Turks and of Germany against France, and where men looked to Vienna for the careers and honours unattainable at home. The imperial dignity was therefore an attractive prize, and for some time before Charles VI died it was clear that it would be a cause of strife, since many rulers had an interest in seeing that it did not go to Maria Theresa's husband Francis, who as the former ruler of a small duchy within the French orbit (Lorraine, which he had exchanged for Tuscany on his marriage in 1736) could plausibly be held to be unsuitable. If, however, Francis were not elected emperor, the successful candidate would have to be endowed with territories appropriate to the dignity, a task which was seen to be incompatible with leaving the Habsburg inheritance intact.

Frederick the Great's Invasion of Silesia, 1740–41.—The war which everyone expected was begun by Frederick II, later known as the Great, who had acceded to the throne of Prussia in May 1740. Charles VI died on Oct. 20, 1740. On Dec. 16 Frederick invaded Silesia, which formed part of the Bohemian lands and was one of the richest of the Habsburg territories, with a population of just over 1,000,000, or nearly 50% of that in Frederick's own territories at his accession. Since Frederick had given his formal consent to the pragmatic sanction he broke his word when he invaded Silesia and was also guilty of an act of unprovoked aggression. In consequence he incurred much odium at the time and later. Among his contemporaries, however, the reasons for this seem to have been the unusual degree of success that he achieved, his cynical indifference to standards of international behaviour which everyone professed but no one followed and, in general his having thrust himself into the circle of the great powers while going out of his way to express his contempt for their rulers and ruling classes. To invade, on the other hand, as he had done, a defenseless neighbour in violation of a treaty and without a declaration of war, was perfectly in accordance with 18th-century practice.

Frederick overran Silesia in a matter of weeks, for the province was wholly unprepared for attack, and since he had timed his invasion for the end of the campaigning season, the Austrians were unable to bring up reinforcements until the spring. Apart from his openly confessed desire to distinguish himself, his action had only one purpose: to acquire the resources necessary if he were, as he said, to raise Prussia "out of the dust." In return for Silesia he offered Maria Theresa a large sum of money and the promise to support her husband at the forthcoming imperial election. Maria Theresa, however, against the advice of most of her ministers, turned these proposals down, and since Frederick was still without allies, the success of his gamble was put in jeopardy.

Before 1740 Prussia had never felt strong enough to pursue an independent policy. Not only was its population very small (about 2,250,000); its territories were among the poorest in Europe west of the Vistula and scattered over a large area without defensible frontiers. That so inconspicuous a state, apparently so ill-provided with the sinews of war, should challenge a major power was generally seen as the height of rashness. When Louis XV of France heard the news he described Frederick as a madman. There

was, however, more in Frederick's favour than at first sight appeared. By virtue of an economy and a social structure organized primarily with a view to military needs, Frederick possessed an army of more than 80,000 men—a number about four times as large, by 18th-century standards, as a state of average wealth and with Prussia's population could be expected to maintain. In equipment and discipline this army had no equal in Europe. It had moreover the unique advantage of being commanded by an autocrat of exceptional talents who had the power to order personally every aspect of military affairs, as well as every aspect of civil affairs as far as 18th-century conditions permitted.

By comparison the Habsburgs were poorly prepared for war. On the one hand, they had just been defeated by the Turks, with whom they had concluded a disadvantageous peace in 1739, so that their treasury was empty and their army, normally 160,000 strong, had been reduced to less than half this number; on the other hand, they lacked the means to mobilize their still considerable resources. For in the hereditary lands, the centre then and later of Habsburg power, the authority of the central government was negligible, depending on the good will of a large number of estates. Even when these estates could be prevailed on to grant taxes and to release men for military service, they never fulfilled their promises, and against this recalcitrance the crown had no remedy. In no other dominions of comparable standing was there so glaring a contrast between the wealth and power of individual subjects and the poverty and weakness of the crown. Thus, when the first battle of the Silesian campaign was fought at Mollwitz on April 10, 1741, 16,000 ill-trained and ill-equipped Austrians faced 24,000 Prussians and were defeated.

French and British Involvement.—The Prussian victory at Mollwitz made certain that the quarrel over Silesia would expand into a European war, since it confirmed the suspicion that the Habsburg dominions were incapable of self-defense and thus ripe for partition. The state that principally desired to exploit these possibilities was France. The French had a long tradition of hostility to the Habsburgs dating from the 16th century, when the emperor Charles V had threatened them with encirclement. Since the Thirty Years' War this danger had, admittedly, ceased to exist. Indeed from that time onward it was France that was the menace, not only to the Habsburgs but also, under Louis XIV, to the balance of power throughout the world. Louis XIV's defeats, moreover, had been principally engineered not by Austria but by Great Britain and the United Provinces of the Netherlands. Notwithstanding these facts, however, the old anti-Habsburg tradition lived on in France, as did the newer tradition, sanctified by Louis XIV's victories, though temporarily discredited by his defeat, of French hegemony in Europe.

When Charles VI died there had been two schools of thought in France on the subject of foreign policy, of which one held that the French ought not to take any steps which would lead to war in Europe. This point of view had at first commended itself to Louis XV and to his chief minister, Cardinal Fleury, who knew that French finances could not stand the strain of a continental war as well as of the war at sea with Great Britain that was imminent. It was, however, the other view that prevailed, sponsored by the comte (later Marshal and duc) de Belle-Isle (*q.v.*), who represented the opinions of the army and the nobility at court. Belle-Isle, as Fleury once put it, became the "inventor and architect of that glorious scene"—a Europe united against Maria Theresa. At his instigation the French concluded a treaty with Prussia (the treaty of Breslau, June 5, 1741) in which they recognized Prussia's right to the bulk of Silesia. While not themselves declaring war against Austria, they provided Charles Albert of Bavaria with troops, money and instructors to train his army, in order that he might conquer territories in the hereditary lands to sustain the imperial dignity to which they proposed to raise him; by a mixture of bribery and coercion they induced the ecclesiastical electors on the Rhine to support his cause; by similar means they won over the Saxons, whose natural inclination was to fear Prussia and support Austria; they spurred on the Swedes to attack Russia so that the Prussians might be freed from the fear of a Russian invasion (a project which achieved its purpose even though the Swedes were defeated); finally they facilitated a Spanish attack on the Habsburg territories in Italy.

When Philip V, grandson of Louis XIV, was established by the treaty of Utrecht on the throne of Spain, the Spaniards were deprived of their Italian possessions because Great Britain feared the Bourbon interest in this strategically vital area. Since then they had been struggling to get them back. Don Carlos, the eldest son of Philip V by Isabella Farnese (and afterward Charles III of Spain), had succeeded in acquiring Parma in 1731 and the kingdom of Naples in 1734. Now Isabella planned to secure an appanage in Lombardy for her second son, Philip, and to turn the Habsburgs out of Italy. When she embarked on these projects in the autumn of 1741 she had French permission to move her armies through France, and French naval escorts protected the troops that went by sea.

Thus the vultures gathered around the prey and organizing them into an alliance had been an easy task for the richest and, militarily, the strongest power in Europe. The French themselves engaged in the undertaking not on behalf of any national or even dynastic interests, but in the belief that as the greatest nation in the world, in the arts of peace as well as war, it was their due and destiny not indeed to conquer Europe as Louis XIV had tried to do, but to dominate it by means of client states.

As was natural in these circumstances, Great Britain saw France from 1741 onward (as between 1689 and 1714) as the principal disturber of the peace of Europe. The British feared a French hegemony for many reasons, but essentially because the French, like themselves, were a great maritime and colonial power and, as it seemed clear to many, the fate of colonies and commerce would be settled on the battlefields of Europe. A state that dominated the continent could close the continental ports to British exports, deny access to the indispensable sources of naval stores in the Baltic, secure the ships and crews of the smaller maritime powers and so in the long run control the seas, oceans and colonies of the world. Admittedly this argument was always rejected in many circles in England and by every parliamentary opposition. These people maintained that Great Britain should fight only at sea and leave the quarrels on the continent alone. Their point of view was, however, so plainly untenable that the maritime or "blue water" school found no adherents among people in authority. When French armies were on the march in Europe no British government ever failed to intervene.

Throughout the long duel between France and Great Britain which lasted from 1689 to 1815, war on the continent was always accompanied by war in the colonies. Apart from the Netherlands East Indies, which were not involved in the 18th-century wars, the principal colonial areas of the world—the Caribbean, North America, India and the slave stations on the coast of West Africa—were a scene of continuous strife between the colonial powers, of which by 1740 much the strongest were the British and the French. The conflicts originally arose out of local circumstances, for the European trading stations and settlements were everywhere contiguous and in competition. The stock of national animosity, however, to which these various disputes contributed, was powerfully increased by current views on the purpose and functions of colonies and trade. With their ambitions or fears centred on Europe, governments generally and, in the existing circumstances, justifiably believed that their revenues and thus their power turned largely on the volume of their foreign trade and on a favourable balance of trade. They saw trade as a means of economic warfare to be waged by tariffs and navigation acts backed by naval force.

In 1739 the conflicts endemic in all the colonial areas had exploded into war in the Caribbean. The Spanish government claimed a monopoly of the trade with its colonies in America, but was unable to exploit it since Spain could not produce sufficient commodities to satisfy the colonists' needs. This state of affairs provided the more highly developed nations with an irresistible temptation and the British in particular perennially succumbed to it in violation of the Asiento (*q.v.*) treaty. As a result the so-called War of Jenkins' Ear (*see* JENKINS, ROBERT) broke out between Great Britain and Spain in Oct. 1739. The French could

not remain indifferent, since a British victory would jeopardize their vital interests in the western hemisphere. The fear of a British hegemony there, and also in the Indian ocean, dominated French thinking to the same extent as the fear of a French hegemony in Europe dominated British thinking—and with as much justice; for although France was an overwhelmingly agricultural nation, the French capacity to make war depended heavily on the revenues derived, directly or indirectly, from their colonial trade. At the end of Aug. 1740 Fleury had sent two powerful battle squadrons to the French West Indies, and France had become Spain's auxiliary, though without declaring war on Great Britain.

As a consequence the war in Europe expanded into a world war. As Frederick the Great once put it: ". . . thanks to the politics of our century no dispute, however small, can arise anywhere that may not spread to, and set by the ears, the whole of Christendom." He saw this as the work of Great Britain and France. They, he said, had "a preponderance over all the other powers. They look on themselves as the leaders of two rival gangs to which all kings and princes must attach themselves."

From the start the British thus had an interest in supporting Maria Theresa, and parliament voted her £300,000 in the session of 1741. Throughout that year, however, and for a part of 1742, they could provide no physical help. Apart from any other reason, they lacked a base in Europe, since Hanover, which should have served this purpose, succumbed to enemy pressure in Sept. 1741. With a French army on his western frontiers and a Prussian army to the south, George II, to the rage and fury of his British subjects, felt himself obliged to declare Hanover neutral.

The Situation in Central Europe, 1741–45.—Maria Theresa was thus left to face alone the formidable forces of Belle-Isle's coalition. French and Bavarian troops overran Upper Austria in the summer of 1741 and pushed north into Bohemia. In November they captured Prague. For a number of months after the French plans went into operation it did indeed seem that the Habsburgs were doomed. Maria Theresa's chancellor, Count Philipp Ludwig von Sinzendorff, compared their position to that of a drowning man: "The water," he said, "is up to our necks."

Maria Theresa, however, though only 24 and wholly without experience, never lost her courage. Against the advice of most of her ministers, of her husband and of the British government, she refused to negotiate with the enemy, pointing out that if she were to make concessions these would only lead to further demands. Forced to flee from Vienna before the advancing French and Bavarians she went to Pressburg (Bratislava in Slovakia). There, again contrary to the advice of her ministers, who were familiar with the Hungarian tradition of exploiting Habsburg difficulties, she addressed the Hungarian parliament. Speaking without notes (though not without tears) she besought the Hungarian magnates and gentry for help. Overcome by emotion at the sight of their young and beautiful queen in distress, they responded to the appeal. They promised 100,000 men. This famous episode, however, turned out to be of more sentimental than practical significance. Of the promised 100,000 only 20,000 materialized and they were without discipline, training or equipment. It was in fact not so much the Hungarian contingents that saved the Habsburgs, at this juncture, as Maria Theresa's determination not to give in and the difficulties that beset the allies.

The French and Bavarians fought in enemy territory at a considerable distance from home while the Austrians fought on their own soil. This was a great advantage in an age when bad communications usually prevented large-scale movements in winter and at all times set narrow limits to the numbers of men and the quantities of supplies that could be moved. Since the system of promiscuous plunder in vogue during the Thirty Years' War had by now been prohibited in the interests of discipline, and since the system of organized plunder, or requisitioning from conquered territories, had not yet been adequately developed, food for the troops and, particularly, fodder for the animals, were apt to be the Achilles' heel of every commander. To these and other obstacles placed by contemporary practices and conditions in the way of overwhelming an enemy by weight of numbers were added the obstacles created by the French and Spanish courts, where incompetent people were often appointed to command and where the plans of the competent were disrupted by ignorant and ill-advised interference. Finally there was the difficulty of keeping the alliance together.

In central Europe the Prussians, the French and their satellites had no interest in common apart from the desire for plunder. Each was therefore suspicious of the others and afraid of being sacrificed to their ill will or inefficiency. Frederick, in the autumn of 1741, had wanted the French and Bavarians to capture Vienna in order to bring Maria Theresa quickly to terms, as he lacked the resources for a long war, but the French and Bavarians had preferred to go to Bohemia—among other reasons, in order to crown Charles Albert king there and secure the Bohemian vote in the imperial election. In Bohemia, however, particularly in view of their projects to conquer territories in this region for Saxony, they were uncomfortably close to Silesia. Frederick had no wish to become the pawn of his more powerful allies. He also urgently needed winter quarters for his troops. Thus in contravention of the treaty of Breslau, he concluded the convention of Kleinschnellendorf with Austria on Oct. 9, 1741, by which the Austrians surrendered to him the key fortress of Neisse and thus left him in undisturbed possession of upper Silesia. Freed from the need to fight the Prussians, the Austrians then drove the French and Bavarians out of Upper Austria, invaded Bavaria, and on Jan. 24, 1742—the very day on which Charles Albert was elected Holy Roman emperor as Charles VII—captured Munich.

It was understood that the convention of Kleinschnellendorf should be confirmed by a definitive treaty in the following December. This treaty, however, was never signed. Exclusively preoccupied with the conquest of Silesia, Frederick realized that the attainment of his object depended on a balance of power between France and Austria. After Kleinschnellendorf he moved in and out of the war as this principle dictated. He attacked Maria Theresa at the beginning of 1742, and his victory at Chotusitz on May 17 forced her to cede Silesia to him by the treaty of Berlin in the following July. He came into the war again in alliance with France at the beginning of 1744 because of the British and Austrian successes at the end of the previous year. Hampered by inadequate resources and transportation difficulties, and jeopardized by a mistaken strategy in the invasion of Bohemia in the autumn of 1744, his army was nearly destroyed. Frederick was, however, saved by his indomitable will and by his skill in battle. A series of remarkable victories (Hohenfriedeberg on June 4, 1745, Soor on Sept. 30, Kesselsdorf on Dec. 14) established his reputation as one of the great generals of the age and earned him the title of "the Great." They enabled the British, concerned that Austria's war effort should be concentrated against France, to induce Maria Theresa to accept Frederick's terms. She ceded the greater part of Silesia to him by the treaty of Dresden (Dec. 25 1745). The stalemate that developed between the other belligerents after this permitted him to feel secure until 1748.

The War in Western Europe.—The British between 1739 and 1748 were in no position to repeat what they had done in the War of the Spanish Succession or to forestall what they were to do between 1759 and 1762, for their political system was functioning according to its usual form and not as it could sometimes function in an emergency. Power was divided between the king and his ministers and ministers were divided among themselves. In order to stay in power they needed on the one hand the royal favour, which always made them objects of suspicion, on the other hand a majority in the house of commons, where there were no organized parties and opposition was always irresponsible. The disharmony which this state of affairs produced was now greatly aggravated by the belief that George II intended to sacrifice British interests to the interests of Hanover. Not surprisingly in these circumstances it proved impossible to formulate coherent plans, to correlate political and military strategy or to inspire that confidence in British leadership which was essential to co-operation among the allies.

In May 1742 the British had succeeded in procuring a base at Ostend (in the Austrian Netherlands) which the United Provinces had the right to garrison. The reluctant Dutch, Great Britain's

principal allies during Louis XIV's reign, were induced to enter the war in the following year. At Ostend was assembled the so-called pragmatic army of British troops and German mercenaries which by the middle of 1743 was about 30,000 strong. During 1742 and 1743 its commander, Lord Stair, formed plans for invading France in conjunction with the Austrians (during one of the interludes when they were freed from the Prussian menace) and for marching on Paris. He was, however, never allowed to put these plans into operation. George II, of unimpeachable physical courage but otherwise wholly unfitted for military command, insisted on exercising his rights as commander in chief. Although, because of the mistakes of the French, he managed on June 27, 1743, to extricate himself from an impossible position and to win the battle of Dettingen, he ruined the chances of what might have been a decisive campaign. Nevertheless the pragmatic army in 1743 fulfilled one of its main purposes, for it prevented the dispatch of French reinforcements to the Danube and Bohemia and by the end of the year the French had been expelled from Germany.

Louis XV now concluded that he could serve his interests best by dropping the pretense that he was acting only as an auxiliary in the succession dispute. He decided to attack England directly by means of a surprise invasion on behalf of the Jacobites. When news of this project leaked out, so that it had to be abandoned, he changed his objective to the conquest of the Austrian Netherlands, an area vital to the security of Great Britain. He declared war on Great Britain in March 1744 and on Austria in the following April. Maurice de Saxe (*q.v.*) was put in command of the French army in the spring of 1745, when—for the first time in this war and the last time before 1789—intrigues at court and the other vices of a corrupt political system failed to obstruct the rise of a great soldier to a position of undisputed control. Saxe defeated the British and their unco-operative allies, the Austrians and the Dutch, under the command of the duke of Cumberland, at the decisive battle of Fontenoy on May 11, 1745. As a result, and because the British had to withdraw a large part of their forces for use against the Jacobite rebellion that year, the French had the allies at their mercy. They conquered the whole of the Austrian Netherlands by the end of 1746 and invaded the United Provinces in 1747. They would have conquered that country also if Louis XV had not come to the conclusion that he could not continue the war.

Louis felt himself forced to this decision through lack of money and the apparent impossibility of raising further taxes or loans. Waste, extravagance and the absence of any rational system of priorities had distinguished French policy and practice since the beginning of the war, and British successes at sea had disrupted the French economy and reduced the government's revenues.

The War at Sea.—Success at sea came slowly to the British. Admittedly even in 1739 Great Britain was the strongest naval power in the world. The two-power standard which prescribed that the Royal Navy should be equal in strength to the combined navies of France and Spain was achieved on paper and was probably exceeded in fact. A strong naval tradition and a general awareness of the navy's vital importance increasingly insulated the navy against political intrigue and royal interference. Nevertheless at the beginning of the war it had far too few ships for its needs, and the war at sea suffered from the same lack of direction as did diplomacy and military strategy.

During the period (1739–44) when Great Britain was at war with Spain, but only with France as Spain's auxiliary, British efforts had first been directed toward destroying Spain's warmaking capacity by capturing the focal points of the trade with America on which the Spanish government depended for its revenues. These projects came to a dismal end with the disastrously mismanaged expedition against Cartagena in 1741. From the beginning of 1742 the navy was able to prevent the movement of French and Spanish troops to Italy by sea, but it had not established supremacy in the Mediterranean by the time France declared war. From 1739 it had been burdened, as always, with a huge number of defensive duties and these became vastly more onerous in 1744 when British ships everywhere became legitimate objects of French attack, when hordes of privateers were let loose on British merchantmen and when Great Britain itself was menaced (though imminently only in the spring of 1744) by invasion. For a number of years British naval forces were dissipated without adequate plan between their many tasks.

The French, however, were unable to profit from the period of weakness and divided councils in Great Britain. The British government had to render account of its actions to parliament and so was under some compulsion to cut its coat according to its cloth. The French government was not. When it had embarked on its continental ventures in 1741 its navy and its naval expenditure were inferior to the British and its mounting military commitments increased the gap. Money was the crucial shortage, and it gave rise to other shortages not always obviously attributable to it, particularly shortages of crews and timber. Ships and crews, therefore, became increasingly precious and one hesitated to risk them in battle if this could be avoided. Thus in 1744, after the invasion project and the attempt in the battle of Toulon (February) to destroy British power in the Mediterranean had failed, the French ceased to challenge the British battle fleets, but employed their warships principally to harass British trade and to protect their own. The nemesis that attends this way of proceeding descended on them in 1747. In that year Adm. George Anson solved the problem of naval priorities by means of the "golden rule" which was established as the pivot of British naval strategy. This prescribed a strong western squadron, large enough to spare detachments when required for other areas, whose principal purpose was to protect British and attack French merchant ships as they left or approached their home ports. Armed with this weapon the British moved over to the offensive in 1747. The western squadron fought a number of engagements with the heavily protected French convoys sailing to and from India and the West Indies. The French lost a great many escorts (as well as merchant ships) which they were unable to replace. Thus they began the descent that led inevitably to defeat; for with inadequate escort (and finally with none at all, as the escorts came to seem only a provocation to attack) the French merchant ships were an easy prey. In the end, since no one would insure them, they ceased on many routes to sail at all. Consequently in most of the principal towns of France bankruptcies and unemployment spread as merchants, shipowners and shipbuilders lost their livelihood. Meanwhile, in coastal districts suffering from poor harvests to which the British blockade made it impossible to bring grain by sea, the result was famine. In these ways the French economy was threatened with collapse. The controller general of the finances, J. B. de Machault d'Arnouville, said in 1748 that he saw all hell opening before him if the war at sea went on.

These disasters were of a kind which a country largely self-sufficient in foodstuffs and raw materials should have been able to overcome. Saxe pointed out that France had many resources left and that it was these resources, not the amount of money available to the crown, that counted. Louis XV's government, however, reacted after the fashion of 18th-century governments. It lacked the authority, the resolution and above all the desire to follow Saxe's advice, which would have involved drastic changes in the system of taxation and interference with the rights of property. Therefore, in order to restore their trade and to preserve their colonies, all of which for lack of naval ships to reinforce and defend them must sooner or later have fallen to British attack, the French were prepared to surrender their conquests. The British, who had achieved the objects for which they had entered the war and who disliked its expense, were prepared to do the same. In point of fact they had only one conquest to surrender—the fortress of Louisburg, on Cape Breton Island—but as the indispensable base for the conquest of Canada it was of great strategic value. It had been captured in 1745 through the initiative of the Bostonians.

The War in Italy.—The decision to make peace brought to an end the war in Italy where the Spaniards had failed to achieve their aims. By the treaty of Fontainebleau (Oct. 1743) Louis XV had agreed to enter the Italian war as a principal on the Spanish side. British naval power in the Mediterranean, however, had

virtually prevented the movement of enemy troops to Italy by sea since the end of 1741, so that the only way of invading Lombardy was overland through Savoy and Piedmont. The attitude of Charles Emmanuel III of Sardinia, who owned these territories, consequently became of cardinal importance. He himself wanted the duchy of Milan and saw that his interest lay in preserving a balance of power between the Habsburgs and the Bourbons. He sat on the fence, inclining to the side of the Habsburgs as the weaker party, until Sept. 1743. Then by the treaty of Worms he agreed to put 40,000 men into the field in support of Maria Theresa. The price of his alliance was £200,000 a year from Great Britain and various territories in Lombardy, which the British forced Maria Theresa to cede to him under threat of stopping their subsidies to her. In spite of the difficulties of conquering Piedmont by invasion through the mountains from the west, the French general Jean Maillebois nearly achieved the feat in the autumn of 1745. This was the one occasion when either side came within reach of decisive victory. Maillebois, however, failed to achieve it because the Spaniards would not agree to his plans and were supported by Louis XV.

The Peace of Aix-la-Chapelle.—The general peace treaty of Aix-la-Chapelle was signed on Oct. 18, 1748. Though Frederick the Great had taken no part in the negotiations the treaty guaranteed his possession of Silesia. It also guaranteed to Charles Emmanuel all the territories which Maria Theresa had ceded to him by the treaty of Worms, apart from Piacenza which was given to Don Philip together with Parma. With these exceptions the *status quo ante bellum* was restored. Louisburg was handed back to the French, and Madras, which the French had captured in 1746, to the British. The Austrian Netherlands, in accordance with Great Britain's vital interests, were returned to the Habsburgs. In general, in fact, the treaty of Aix-la-Chapelle, insofar as it was concerned with western Europe and the world overseas, put the clock back to 1739. The war had settled nothing. Indeed it had exacerbated existing rivalries, and the next war was to start in America in 1754 because of disputes that the peacemakers in 1748 had made no attempt to solve.

In central Europe, on the other hand, the war settled a good deal. Admittedly the Habsburgs retained the bulk of their inheritance intact. They also got back the imperial dignity, for the emperor Charles VII (Charles Albert of Bavaria) had died in Jan. 1745, and in the following September Maria Theresa's husband was elected to succeed him as Francis I. The Habsburgs, moreover, had learned a lesson. They could not have survived without the sea power, subsidies and military intervention of their British allies, but it seemed to them that their losses were due to the selfishness of, and their financial dependence on, Great Britain, and they were determined that next time they would stand on their own feet. After 1748 Maria Theresa embarked on her great reforms, with the result that by 1756, when the Seven Years' War broke out, the Habsburgs' warmaking capacity was stronger, relatively as well as absolutely, than it had been in 1740. All the same the Habsburgs never permanently regained the hegemony which they had exercised in Germany between 1648 and 1740. Though they did not recognize the loss of Silesia as final, or Prussia's position as a great power, and engineered the next war on the continent to get back the first and destroy the second, they failed in their endeavours—albeit by a narrow margin. Prussia had come to stay.

Even at the time the rise of Prussia was a fact of great significance, synchronizing as it did with the decline of the United Provinces, which the War of the Austrian Succession made plain, and accompanied as it was soon to be by the rise of Russia, whose intervention in world events was foreshadowed when in 1748, though too late to take part in the fighting, a Russian army of 30,000 men, for which the British paid, was sent to the Netherlands. These changes destroyed the equilibrium established at Utrecht after Louis XIV's wars and set up in its place one of another kind; one, moreover, that was to endure, apart from the interlude of the French Revolutionary and Napoleonic Wars, substantially unchanged until 1914. As William Pitt the elder put it in 1762: "Such are the great events by which the balance of power in Europe has been entirely altered since the time of the grand alliance" against Louis XIV.

AUSTRIC LANGUAGES are a proposed family of languages that are spoken from the island of Madagascar to the Himalaya mountains, and from New Zealand to Easter Island. The Austric language family, proposed by Wilhelm Schmidt in 1906, connects the Malayo-Polynesian languages and the Austroasiatic languages (*qq.v.*) by presumed similarities in vocabulary, word formation and basic sounds. This grouping inspired other scholars to reach further and suggest links with Japanese, Indochinese American Indian, Australian and Sumerian. In 1942 Thomas Sebeok noted the need for caution, demonstrating that reliable conclusions could not be drawn without good descriptive grammars, reconstructed proto vocabularies and adequate comparison of protoforms to establish systematic correspondences. Concurrently Paul Benedict indicated the utility of Schmidt's hypothesis for interpretation and analysis.

AUSTROASIATIC LANGUAGES. According to a hypothesis promulgated especially by Wilhelm Schmidt, there exists a family of Austric languages (*q.v.*), with two major branches: the Malayo-Polynesian languages (*q.v.*) (including most languages of Malaysia, Polynesia, and Melanesia); and the Austroasiatic The numerous tongues involved in the Austroasiatic branch extend over a vast area, the limits of which are: Kūrkū, of the Chota-Nagpur group, in India, to the west; Bahnar, belonging to Mon-Khmer proper, to the east; the Semang and Sakai languages of the Malay peninsula, to the south; and Palaung of the Salween basin, with Khasi, defining the northern boundary.

Three subfamilies are said to comprise Austroasiatic by those who accept the hypothesis in its fullest form: (1) Mon-Khmer, further subdivided into (*a*) Mon-Khmer proper, (*b*) Cham, Jarai Radé and Sedang (more likely Indonesian languages), (*c*) the languages of the Malay peninsula, (*d*) Nicobarese, (*e*) the languages of the Salowen basin, and (*f*) Khasi; (2) the Munda languages (*q.v.*) of the Himalayas and Chota Nagpur; and (3) Annam-Muong (attached, however, by Henri Maspero, who rejects the Austroasiatic alignment, to the Thai family).

Insofar as the proponents of the Austroasiatic hypothesis claim that the relationship among the groups in question is a genetic one, that is, that they are descendants of a common ancestor, they have failed to support their notions with the authority of comparative linguistics. The nature of the data adduced would seem, however, to justify serious attempts to reconstruct parent forms.

AUTHORITARIANISM: *see* Absolutism, Political.

AUTOBIOGRAPHY, the account of an individual human life, written by the subject himself. In the broadest sense any self-written account of one's life and times may be thought of as autobiographical, but autobiography as a literary genre stands apart from certain related forms—notably the personal essay, the diary, the travel journal and the autobiographical novel. It must, obviously, be composed by the subject himself, not ghost written by a professional biographer; yet it may be dictated to an

amanuensis, and it may be written—though this is seldom the case—in the third person. It must attempt to survey, in retrospective mood, a considerable portion of life, if not an entire life; and it must take the form of an ordered narrative, with deliberate selection and shaping of material (though not constructed as fiction) to compose an artistic whole. Above all, its underlying principle must be scrutiny of the self, with outside happenings, persons encountered, and observations admitted primarily as they impinge on the consciousness of the person on whose character and actions the writing is focused. These restrictions, it will be seen, rule out such works as Montaigne's *Essays*, Pepys's *Diary*, Coleridge's *Biographia Literaria*, Wordsworth's *Prelude*, and Joyce's *Portrait of the Artist as a Young Man*. All of these are autobiographical in a broad sense, but to consider them as autobiographies would bring into this genre a very large part of the world's literature, since it is rare indeed to find a work of imagination which contains no element of self-revelation.

The one related form which it is difficult, if not impossible, to separate logically from autobiography is the *memoir*. The writer of memoirs is usually a person who has played a distinguished role in history, or who has had the opportunity to observe, at close range, history in the making. The Civil Wars in England in the 17th century produced a flood of such reminiscences, of which the *Memoirs* of Sir Edmund Ludlow (1617?–1692) and Sir John Reresby (1634–1689) are representative. The French have particularly excelled in this genre; three outstanding examples from the 17th century are the *Mémoires* of Madame de Motteville (c. 1621–1689), of the Cardinal de Retz (1614–1679), and the Duc de Saint-Simon (1675–1755). The memoir, however, while it inevitably reveals much of the tastes and character of the writer, is primarily focused on outward happenings and on other persons; hence it is not, in the strict sense, a form of autobiography. The word "autobiography" was not coined until the close of the 18th century; prior to that time "memoirs" was frequently used for works which would now be called autobiographies. The distinction between the two forms often turns out to be one of degree rather than kind, depending on the amount of self-revelation contained in the memoir; but on the whole it seems best to restrict autobiography to the self-written biography in which the focus is primarily on the self rather than on outward events.

Early Autobiography.—Writers of antiquity often reveal a great deal about themselves—Horace, for instance, in his poems, and Cicero in his letters—but there are, strictly speaking, no examples of autobiography surviving from classical literature. Although a sustained tradition of autobiographical writing did not begin until considerably later, the *Confessions* of St. Augustine (354–430) deserves the title of the earliest extant autobiography. Written about A.D. 399, it describes, in lively and charming detail, the early life of Augustine, his affection for his mother, his striving against sensuality and sin, his search for philosophic truth, and, most dramatically, his conversion, in the summer of 386, to Christianity. Candid and unassuming, devout in spirit, it remains to this day one of the best of autobiographies and one of the most influential on succeeding writers. The *Retractions*, composed shortly before St. Augustine's death, affords a survey of his writings and stands as a kind of supplement to the earlier and more famous autobiography.

The earliest autobiographical account in English which has come down to us is the strange and absorbing *Book of Margery Kempe*, written in the early 15th century but not discovered until 1934, in a private library in Lancashire. It is the narrative of the spiritual struggles and adventurous life of a devout—and somewhat trying—woman of Lynn, born about 1373, who in 1414 made a pilgrimage to the Holy Land and was in Rome for the celebrations held in honour of the canonization of St. Bridget. She made other journeys too, and her "book" not only provides one of the most vivid accounts of the life of a pilgrim in the middle ages but also (and here it qualifies as an autobiography) is a realistic portrayal of an interesting and complex personality. Her narrative, dictated at different times to two amanuenses, was published (in a modernized version) by the owner of the manuscript, William Butler-Bowdon, in 1936, and (the original text) by S. B. Meech for the Early English Text society in 1940.

From the Renaissance to the 19th Century.—The tradition of autobiographical writing begins in the Renaissance, with the fascinating *Vita di Benvenuto Cellini*, partly written and partly dictated between 1558 and 1562, and the *De vita propria* of the Italian physician Geronimo Cardano, begun as "a natural history of himself" in 1574. The upsurge of freedom from medieval restraints, the spirit of scientific inquiry, and the new interest in the human personality—all characteristic features of the Renaissance—undoubtedly contributed to the development of a genre which was to increase in the succeeding centuries and to become in the 20th century one of the most popular of all literary forms. Other examples are the narrative of Thomas Whythorne (written c. 1576 and not discovered until 1955), music master to Archbishop Matthew Parker; the vainglorious autobiography of Lord Herbert of Cherbury (written c. 1643 but not published until 1764); the curious *Exemplar humanae vitae* (1687) of Uriel Acosta; and two notable spiritual autobiographies—John Bunyan's *Grace Abounding to the Chief of Sinners* (1666), an extraordinarily frank and vivid account of the inward struggles of one who had "tarried long at Sinai to see the fire and the cloud and the darkness," and the *Reliquiae Baxterianae, or Mr. Richard Baxter's Narrative of the Most Memorable Passages of His Life and Times* (1696), a book which has remained a favourite even with those who have not shared Baxter's religious point of view. Both books seem to have been written not so much as a mode of self-justification as from a strong compulsion to set down the artless record of an inner spiritual struggle. "I could have stepped into a style much higher than this," writes Bunyan, "and could have adorned all things more than I have seemed to do; but I dare not. God did not play in convincing of me, wherefore I may not play in my relating of these experiences, but be plain and simple, and lay down the thing as it was." To these may be added the remarkable series of autobiographies composed by women in the 17th century—the fragmentary "life" of herself prefixed to the *Memoirs* of her husband Colonel Hutchinson (1615–1664) by Lucy Hutchinson; the *Memoirs* of Anne, Lady Fanshawe (1625–1680); the autobiographical account of Mary Rich, countess of Warwick (1625–1678); and the "True Relation" of Margaret Cavendish, duchess of Newcastle (c. 1624–1674), "written by herself." Although most of these were not published until the 19th century, they afford vivid descriptions not only of the times in which they were written but also of the personalities of interesting and strikingly different women of the 17th century.

The 18th century witnessed the writing of several autobiographies which have become classics of world literature: the autobiography of Benjamin Franklin (1795); the series of memoirs of himself composed by Edward Gibbon (1798); and, above all, the *Confessions* of Jean Jacques Rousseau (1781–1788) whose importance to the development of autobiography is evidenced in his insistence, at the beginning of the *Confessions*, on his unique individuality, and in the discussion which his autobiography aroused, particularly in England, of the proper evaluation of egotism. The number of autobiographies at this time is too great to be enumerated in detail, but mention should be made of the beautiful *Memoirs of the Life of Elizabeth Cairns* (1762), the spiritual autobiography of a Scottish woman preacher; the lively autobiography of the bluestocking, Mary Delany (1700–1788); the life of the Italian dramatist Vittorio Alfieri (1749–1803), written by himself; and the *Travels* (1790) of John Macdonald, reprinted in 1927 as *Memoirs of an Eighteenth Century Footman*. This century is also notable for a number of autobiographies of actors and actresses, of which the best known is the *Apology for the Life of Colley Cibber* (1740).

It was at this time that the word "autobiography" seems to have come into being. The first example in the *Oxford English Dictionary* dates from 1809, in a remark by Robert Southey on a life of the Portuguese painter, Francisco Vierira, composed by himself. "It is singular," writes Southey, "that this very amusing and unique specimen of auto-biography should have been entirely overlooked" (*Quarterly Review*, i, 283). Curiously enough, in the same issue of the *Quarterly* (May 1809) another writer

(Isaac D'Israeli), reviewing the *Memoirs of the Life and Writings of Percival Stockdale*, and struck with the popularity of this kind of writing, observes that "we shall expect to see an epidemical rage for auto-biography break out" (i, 386). The word is to be found earlier, however, partly as a result of the interest aroused by the translation of Rousseau's *Confessions*. William Taylor, writing in the *Monthly Review* (Dec. 1797) raises the question whether the term "self-biography" can be properly coined: "it is not very usual in English to employ hybrid words partly Saxon and partly Greek: yet *autobiography* would have seemed pedantic" (xxiv, 375). John Foster, writing in 1805, entitles the first of his *Essays, in a Series of Letters to a Friend*, "On a Man's Writing Memoirs of Himself," and although he does not use the term "autobiography," he points to the example of Rousseau and stresses the value of the "deep self-knowledge" which results from this kind of writing, in which "the exterior life will hold but the second place in attention."

The Nineteenth Century and After.—It is not surprising that in the romantic era of Byron and Shelley, with its emphasis upon individualism and the *étalage du moi*, the number of autobiographies should grow at an extraordinary rate. From the early 19th century the amount of autobiographical writing of all kinds has in fact increased so enormously that only a few representative names can be cited—evocations of childhood in works by Alphonse de Lamartine, Ernest Renan, John Ruskin, Maksim Gorki, Selma Lagerlöf, Carl Spitteler and Richard Church; recollections of literary struggles and triumphs by Anthony Trollope, G. K. Chesterton, Joseph Conrad, Norman Douglas, H. G. Wells and W. B. Yeats; accounts of educational experiences in one form or another by Henry Adams, John Stuart Mill, Booker T. Washington and Helen Keller; records of outstanding spiritual adventures by Cardinal Newman, "Mark Rutherford," and Sir Edmund Gosse; and explorations of the inner life by a long series of writers, including Vera Brittain, Sheila Kaye-Smith, T. E. Lawrence, C. S. Lewis and Sir Herbert Read. Autobiography has become in fact one of the most popular and commercially profitable kinds of writing, and "life-experiences" of every type find their way into print. The hairdresser, the store detective, the boxing referee, the charwoman, the newspaper seller, the steeplejack, the movie organist—these and many more have offered their autobiographies to the public. They are entertaining and informative, but only rarely do they combine a sense of artistic form with a perceptive and illuminating scrutiny of the subject. An age, however, which has seen the publication of such autobiographies as Siegfried Sassoon's *Memoirs of a Fox-Hunting Man* (1929), or the series by Mrs. Belloc Lowndes which began with *"I, Too, Have Lived in Arcadia"* (1942), or G. G. Coulton's *Fourscore Years* (1944), or Sir Osbert Sitwell's *Left Hand, Right Hand!* (1944) and its successors, need not despair.

AUTOCEPHALOUS, a term used in the early church to describe bishops who were independent of a superior authority and now used to describe the independent Orthodox churches of Constantinople, Antioch, Alexandria, Jerusalem (*i.e.*, the four eastern patriarchates), Cyprus, Russia, Greece, Rumania, Yugoslavia (Serbian Orthodox), Bulgaria, Albania, Georgia (U.S.S.R.) and Poland. Autocephaly has also been given by the Russian Orthodox Church to the Czechoslovak Orthodox Church. (There is some disagreement as to whether Finland and Mount Sinai should rank as autocephalous churches.) *See* further ORTHODOX EASTERN CHURCH. (H. M. W.)

AUTOCLAVE, a strong closed vessel of metal in which liquids can be heated above their boiling points under pressure, to effect sterilization of instruments and equipment in bacteriology and medicine and to effect chemical reactions. Etymologically the word indicates a self-closing vessel, in which the tightness of the joints is maintained by the internal pressure, but this characteristic is frequently wanting in the actual apparatus to which the name is applied. The prototype of the autoclave was the steam digester of Denis Papin, invented in 1679, which is still used in cooking and called a pressure cooker, but the appliance finds a much wider range of employment in the chemical industry, where it is utilized in various forms in the manufacture of candles, coal-tar colours, etc.

Frequently an agitator, passing through a stuffing box, is fitted so that the contents may be stirred, and renewable linings are provided in cases where the substances under treatment exert a corrosive action on metal.

AUTOCRACY: *see* ABSOLUTISM, POLITICAL.

AUTO-DA-FÉ (more correctly AUTO-DE-FÉ; "act of faith") the name of the ceremony during the course of which the sentences of the Spanish Inquisition (*q.v.*) were read.

The ceremony comprised a procession in which members of the Holy Office, with familiars and agents, and the accused persons who had confessed their guilt and declared their penitence took part; a solemn mass; an oath of obedience to the inquisition, taken by the king and all the lay functionaries; a sermon by the grand inquisitor; and the reading of the sentences, either of condemnation or acquittal, delivered by the Holy Office.

The handing over of impenitent persons, and those who had relapsed, to the secular power, and their punishment, did not usually take place on the occasion of an auto-da-fé, properly so called.

AUTOGAMY (from the Greek *autos*, "self," and *gamos*, "marriage") is the phenomenon of self-fertilization in protozoa and self-pollination in flowers. In some multicellular animals, and the paramecium and certain other protozoa autogamy takes place by the division of the nucleus into halves, which reunite after maturation. Self-pollination in a hermaphrodite flower (as contrasted with pollination of a pistillate by a staminate flower on the same individual of a monoecious plant) frequently occurs at the end of the life of a flower and results in fertilization if cross-pollination has failed. *See* POLLINATION: *Self-Pollination (Autogamy)*; *see* also references under "Autogamy" in the Index.

AUTOGIRO: *see* AIRPLANE; HELICOPTER.

AUTOGRAPH. An autograph is any manuscript written by its author, either in alphabetical or musical notation, in his own hand. A manuscript entirely in its author's writing is also sometimes called a holograph. By common usage the term autograph may also refer to a separate signature. The practice of collecting such signatures dates back to the 16th century, when students in Germany and the Low Countries collected their friends' autographs in small albums known as *alba amicorum*.

An autograph may be a fair copy of an original manuscript made by its author for a friend. The autograph manuscript of Thomas Gray's *Elegy Written in a Country Church Yard* (1751) for example, which is preserved in the British museum, London, is one of several fair copies circulated by the poet among his friends. It adds nothing to our knowledge of the text or composition of the poem, and apart from its considerable "association value" is mainly of interest because it provides an authenticated specimen of the poet's handwriting. It is thus possible for more than one autograph to exist of the same work, none of which is necessarily the original. An autograph may also be an early or

corrected draft, and provide valuable evidence of the stages of composition. The unique collection of literary autographs on permanent exhibition at the British museum contains specimens of autographs, many of them corrected drafts, of most famous writers in English from Sir Thomas Wyatt onward. Other notable collections are to be found in the Bibliothèque Nationale in Paris, the Vatican library in Rome and the Library of Congress in Washington, D.C.

No autographs of Greek or Roman authors survive, although ignorance of paleography occasionally led medieval scholars to describe as being in the hands of their authors manuscripts of classical works which appeared to be of extreme antiquity. In fact, such manuscripts are rarely older than the 6th century A.D. and more often belong to the 9th or 10th centuries.

In the middle ages, literacy was mainly the prerogative of the clergy. It was an age of anonymity rather than individuality and works such as chronicles are often of unknown authorship. Before the invention of printing, theological, historical and literary works were copied in regular "book hands" by professional scribes who were monks. It is thus difficult to speak of medieval autographs, although some manuscripts of chronicles appear to have been actually written by their compilers. However, an autograph survives of the *Gesta Pontificum* by the 12th-century English historian William of Malmesbury, as well as several autographs of Matthew Paris.

Probably the earliest known European lay signature is that of the Spanish captain, The Cid, dated 1096. Official documents of the kings of England were in early medieval times normally validated by the affixing of a seal. Some of the Norman kings signed with a cross. Edward III (1327–77) is the first English king whose writing survives, though he was not the first literate king. Specimens survive of the autographs of all subsequent monarchs.

By the end of the middle ages literacy had become more widespread. The invention of printing ended the large-scale anonymous copying of manuscripts by hand. The hallmarks of individualism became more important. Examples of the autographs of most of the great figures of the Renaissance—Leonardo, Michelangelo, Ariosto, Dürer, to name a few—are preserved in national libraries.

Comparatively few autographs survive of the literary works of the great Elizabethan authors. There are six signatures of Shakespeare, on his will or other official documents, but of his autograph compositions there is only one controversial survivor. The unique manuscript of the play of *Sir Thomas More,* in the Harleian collection in the British museum, contains an additional scene of 147 lines which some scholars believe to have been composed by Shakespeare and to be in his hand. It seems that Elizabethan authors did not greatly value their own literary autographs. Most of the specimens of handwriting from this period are private or official letters which were preserved more for their literary or historical interest than for their value as autographs.

From the 18th century onward the supply of autograph material of almost every notable figure in the arts, sciences or public life becomes more abundant. Huge collections of private and semipublic political papers of statesmen like Lord Liverpool and W. E. Gladstone are preserved in libraries, and include examples of the autographs of almost everyone who was of sufficient importance to put pen to paper.

The popularity of such authors as Burns, Shelley and Byron led to the fabrication of numerous forgeries of their autographs, some of which are still in circulation. These forgeries were made by men who usually had access to only one or two genuine specimens, which they began by tracing, with the result that their forgeries are stiff, exaggeratedly uniform and lacking in the fluency and spontaneity of genuine autographs. The expert can usually detect a forgery by careful comparison with as many authenticated specimens as possible.

Forgeries must be carefully distinguished from facsimiles, which are copies of originals made by lithography or some other reproductive process. Some early editions of Byron's works, for example, contained a facsimile of an autograph letter of the poet. Such facsimiles, if detached from the volumes which they were intended to illustrate, may deceive the unwary, but can usually be distinguished without difficulty from a genuine autograph.

In general it may be said that, the earlier an author, the rarer his autograph. Specimens of the hands of such prolific 19th-century authors as Coleridge or Swinburne appear fairly frequently in the salerooms. Modern documents of any length are frequently typewritten, but an autograph signature remains the normal method of authentication, and many people prefer to write private letters in their own hands.

BIBLIOGRAPHY.—Most national and public libraries have published collections of facsimiles of their autograph manuscripts, for example, *Facsimiles of . . . Autographs in . . . the British Museum* (1895–99). Other collections include *English Literary Autographs, 1550–1650,* ed. by Sir W. W. Greg (1925–32); *English Poetical Autographs,* ed. by D. Flower and A. N. L. Munby (1938). *See* also A. W. Pollard, *et al., Shakespeare's Hand in the Play of Sir Thomas More* (1923); V. H. Galbraith, "The Literacy of Medieval English Kings," in *Proceedings of the British Academy* (1935); the last chapter of P. Lehmann, *Erforschung des Mittelalters* (1941); H. C. Schultz, "Thomas Hoccleve, Scribe," in *Speculum,* xii (1937). (K. W. G.)

Musical Autographs.—Most of what is said of literary autographs is true also of musical autographs, which are collected privately and in libraries both for the information they give to music scholars and for their associative value. The autographs of some of the 48 preludes and fugues by J. S. Bach, and the Beethoven sketchbooks, which are among the most precious of the British museum's collection of musical autographs, throw considerable light on the composers' original intentions and their revision, as do the autographs of Beethoven's opera, *Fidelio.* Autograph manuscripts of music can also be used to correct errors that may have been introduced by copyists in regard to tempo or dynamics, and may provide evidence of authenticity in cases of disputed authorship. For instance, study of the autograph of a composition by J. S. Bach which has long been attributed to his son, Wilhelm Friedemann Bach, reveals that the son's signature has been added to the father's work. Recognition of the importance of such autograph manuscripts has led to the collection not only of originals, but of photostat copies of them, begun by A. van Hoboken in Vienna in 1927, and later by Otto E. Albrecht in the United States. (E. LR.)

AUTOLYCUS, in Greek mythology, the father of Anticlea, mother of Odysseus. Later authors make Hermes his father. He lived at the foot of Mt. Parnassus, and was famous as a thief and swindler. On one occasion he met his match. Sisyphus, who had lost some cattle, suspected Autolycus of being the thief, but was unable to prove it, since the latter possessed the power of changing everything that was touched by his hands. Sisyphus accordingly burned his name into the hoofs of his cattle and, during a visit to Autolycus, recognized his property. It is said that on this occasion Sisyphus seduced Autolycus' daughter Anticlea and that Odysseus was really the son of Sisyphus, not of Laertes, whom Anticlea afterward married.

The object of the story is to establish the close connection between Hermes, the god of theft and cunning, and the three persons —Sisyphus, Odysseus, Autolycus—who are the incarnate representations of these practices.

AUTOMATIC WRITING is script produced involuntarily when the subject's attention is ostensibly directed elsewhere. The phenomenon may occur when the subject is in an alert waking state or may be induced in various levels of hypnotic trance. There may or may not be any correspondence between the agent's conscious mental content and what the hand is recording at the moment of writing. Sometimes what is produced—which may range from seemingly unrelated words, fragments of poetry, epithets, puns or obscenities to well-organized fantasies—can be reconciled with the writer's conscious thoughts, feelings and behaviour. More often, the contents are inconsistent with personal characteristics the subject consciously accepts. Thus during the height of popular interest in the phenomenon (1850–1900) inspiration for automatic writing was generally attributed to external or supernatural forces. Moreover, since automatic writing, which is often different in appearance from the subject's normal style, has occasionally been found to resemble closely the handwriting of a deceased person, such occurrences led to the attribution of mediumistic powers

to some automatic writers (*see* SPIRITUALISM).

Since the advent, around 1900, of theories of personality that reject the hypothesis that there are supernatural influences on behaviour but postulate unconscious (*q.v.*) as well as conscious motivation, the inspiration for automatic writing has been assumed to be completely endogenous. Modern psychodynamic theories of personality propose that traits, attitudes, motives, impulses, memories and even partially developed talents and skills which are incompatible with maintenance of security in significant interpersonal relationships may be dissociated from awareness and rarely expressed overtly in the course of normal waking behaviour. These subconscious characteristics may be revealed, however, in the content of automatic writing. Thus, in both clinical and experimental studies exemplified by investigations of multiple personalities, automatic writing is a valuable technique for gaining access to aspects of personality outside conscious awareness.

In the psychotherapy of personality disorders, especially in hypnotherapy, automatic writing may be induced as a means of achieving insight into unconscious conflicts, fears or impulses which gain overt expression only as symptoms.

AUTOMATION, the name given to an automatic system of working, the difference between automation and mechanization, a related term, being mainly one of degree. (For the origin and development of the word, *see* below.)

Historical Survey.—Mechanization, the substitution of mechanical power for that of men or animals, can be traced back to antiquity. The handling of material provides many examples of the way in which man has sought to lighten his labours by employing mechanical devices—particularly in building, in mining and in the raising of water. Pulleys, cranes and simple conveyors have been known and used for more than 2,000 years. The mechanization of processes, on the other hand, did not become widespread until the beginning of the Industrial Revolution in the 18th century with the inventions of Richard Arkwright, Henry Maudslay, Elias Howe and many others. Simple automatic devices, however, have a long history. The Romans employed them in connection with the handling of water. Automatic striking clocks were in use in the 14th century. Denis Papin invented his steam safety valve in the latter half of the 17th century, and 100 years later James Watt developed the centrifugal governor to control the speed of the steam engine. Automatic devices were also used on early windmills for turning the sails into the wind and for feathering the sails to adjust their speed. The year 1801 saw the introduction by J. M. Jacquard of a loom on which the design of the cloth woven was controlled by the arrangement of pegs on a chain; the control operated on the same principle as that of a piano player. The invention by J. A. Fleming of the thermionic electron tube in 1904 proved to be of immense importance, for all the initial developments in the science of electronics depended upon this device.

By the end of the 19th century many factories were making considerable use of mechanization. They had come into being as a result of new machines, new processes and the availability of power. Even as early as 1775 Arkwright had patented a mill in which raw cotton was processed into thread, the whole work being carried out by machines. A flour mill in which the operations were similarly integrated was designed and built by Oliver Evans in Dec. 1787. About 1800 Eli Whitney built a factory to make firearms having interchangeable parts—a notable advance, for interchangeability is a key to mass production. The famous Portsmouth block-making plant commenced production about 1808; it employed special machinery designed by Samuel Bentham and M. I. Brunel and had an annual output of 160,000 ship blocks produced by 10 unskilled men who did the work previously done by 110 skilled men. Samuel Colt's Hartford works, operating in 1848, was one of the first examples of mass production.

In production operations in a factory there are four basic factors: the handling of material, the processing of material, the control of the operations and the production design of the product, whether it is a simple part or an electric motor. Maximum efficiency will be achieved if these four factors are fully integrated; that is, if the handling methods, the processing plant, the production design of the product and the control system are planned and designed as a whole from the point of receipt of the raw material to the department dispatching the final product.

Since the 1920s the rate of technical advance has rapidly increased. New materials have become available and new methods of processing have been developed; electronics has produced new conceptions of nondestructive testing and new methods of control culminating in the electronic computer. These materials and techniques have made possible an integrated approach in some industries, though even in the 1960s knowledge was not yet sufficient to permit it fully in others. (*See* also TECHNOLOGY, HISTORY OF.)

Origin and Use of the Word "Automation."—"Automation" was first used in 1936 by D. S. Harder, who was then with General Motors corporation in the U.S. He defined it initially as "the automatic handling of parts between progressive production processes." The word appears to have been used as an original term to describe the linking of machine tools with automatic materials-transfer and -handling equipment. He later extended the meaning so that the effects of automatic handling were considered in each and every phase of the manufacturing process. Thus the beginnings of co-ordination are to be seen; the idea was soon developed by other workers in the field so that the term covered the integration of the four factors detailed above. A definition given by L. Landon Goodman in 1956 is: "Automation is the technology of automatic working in which the handling methods, the processes, and the design of the processed material are integrated to utilize as is economically justifiable the mechanization of thought and effort in order to achieve an automatic and in some cases a self-regulating chain of processes."

The object of automation is, thus, to make the best possible use of available resources: man, material, money and machine. (The use of men in the process is not precluded by Goodman's definition.)

A new word without an accepted definition is apt to be variously used. Automation is no exception, and the word is sometimes employed in a reversion toward its original sense to stand for mechanization or to describe a simple automatic device, mechanized handling or a single process with automatic control.

Elements in an Automated System.—An automated system can be considered to be made up of four distinct but closely interlocked parts: (1) the processing system; (2) the mechanical handling system; (3) the sensing equipment; and (4) the control system. In planning an automated system it is necessary to consider all four parts at the same time in order to achieve self-regulation. Included in the term "processing" is the production design of the product. A change of product design, material or specification may allow another method of processing suitable for automation to be applied.

Sensing.—Sensing equipment plays a role analogous to that played by the physical senses. It observes what is happening, sends the information to the control unit and endows the whole system with a predetermined degree of sensibility. Electronic techniques have played an immense part in broadening the range of possible application, so that the physical senses can be considerably extended by these means. Such techniques employ photoelectric cells, infrared cells, high-frequency devices and devices making use of isotopes, X-rays, ultrasonics and resonance. These devices can be very sensitive indeed: not only can an infrared cell measure the temperature of stars, but it can detect, with the aid of only a small reflector, the heat of a 2-kw. electric heater at several miles' distance.

Sensing devices offer numerous advantages. Speeds of operation are many times faster than the maximum possible by human means. There can be no fatigue and absolute accuracy of inspection is ensured. Further, observations can be made in places which are inaccessible to or unsafe for human beings; *e.g.*, in a nuclear reactor. Many quantities and qualities cannot yet be measured

continuously or with sufficient accuracy or reliability, though each year sees their number diminishing.

Control.—Within the obvious limits of magnitude it can almost be said that if a quantity can be measured it can be controlled. One of the earliest studies of the theory of control was made by Clerk Maxwell in the 19th century, but it is only since the 1930s that the common principles involved in a diversity of control and regulating mechanisms have been recognized.

Manual control of an operation means that some person has to regulate the operation in order to achieve the desired result. In the figure (A) a man observes a meter and acts accordingly. He is "closing the loop." But the loop can be closed by a mechanical or electrical control, as shown in (B). A closed-loop system has a control unit which receives information from a sensing element, compares the actual state with that required by the program and, when there is a difference between the two (called the "error"), makes the necessary adjustment to the control element so that the desired state is maintained. This cycle of operations is continuous. A simple illustration is provided by the domestic automatically controlled electric cooker. In this instance the processing unit is the oven, the sensing device the thermostat, the control the on-off oven heat switch and the program the knob and its auxiliary springs, which are turned to a desired position, that is, oven temperature, which then will be automatically held. The method of operation is this: when the thermostat senses that the oven temperature has risen above the level set by the position of the knob, the control device—that is the switch—adjusts the temperature by switching off the electricity; similarly, when the thermostat senses that the oven temperature has fallen below the set level, the control device switches on the current again. Thus the oven temperature is kept reasonably constant between narrow limits. This is an example of a simple form of what is called "on-off" control. More sophisticated types, which do not switch the quantity controlled on or off, but regulate it automatically and continuously, are normally required for industrial applications. In this way not only temperature but speed, moisture, colour, thickness and many other variables met with in practice can be controlled.

Often the terms "automatic control" or "full automatic control" are encountered, and as these sometimes express the difference between mechanization and automation they are worth considering; they are shown diagrammatically in the figure (C) and (D). With automatic control the cycle of operations takes place in accordance with the program fed into the control and a sensing element or a man may inspect the results; if they are not up to the required standard, the material is either rejected or the plant is shut down. With full automatic control (D), the sensing element again inspects the material, but the information in this case is fed back to the control unit, which then automatically makes any necessary adjustments to the process, so that any tendency to deviation in the measured variable of the material is corrected.

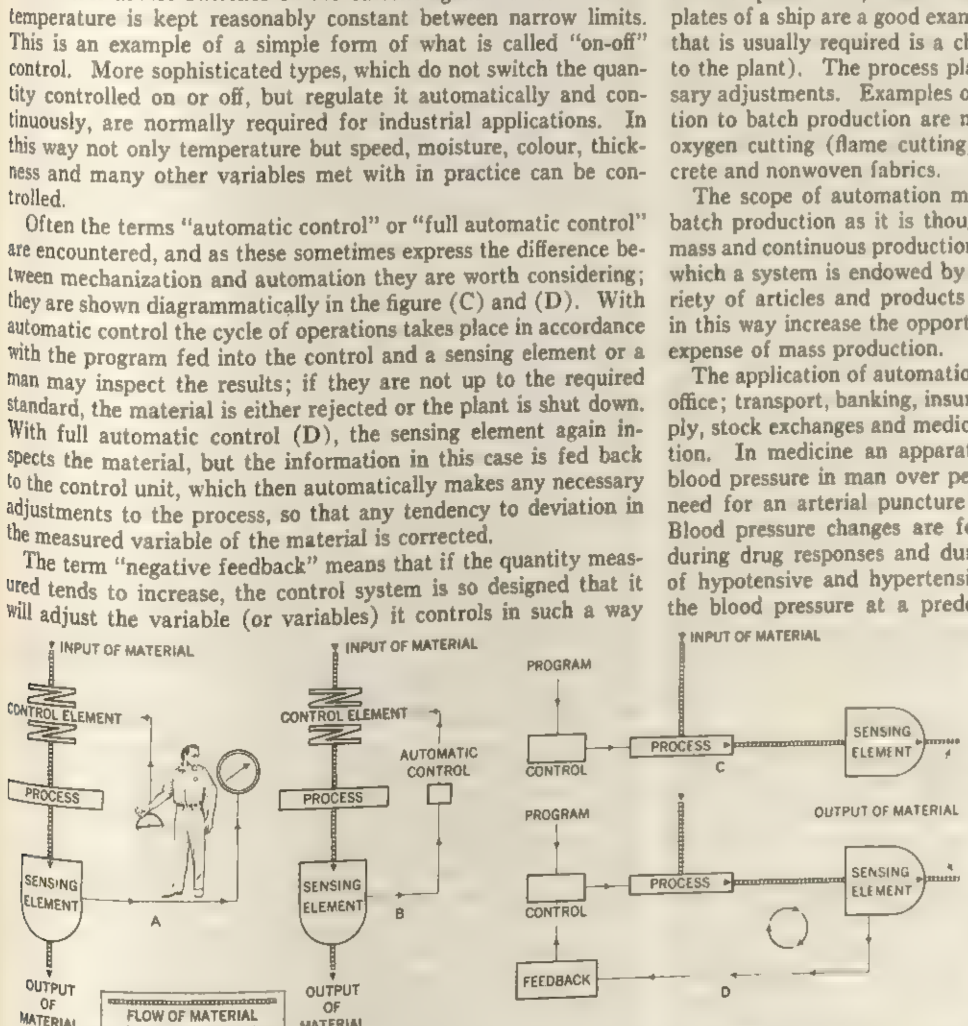
The term "negative feedback" means that if the quantity measured tends to increase, the control system is so designed that it will adjust the variable (or variables) it controls in such a way that the measured quantity will tend to decrease, and vice versa. In this way the output is kept reasonably constant. Automatic volume control in a radio operates in this manner: when the signal received begins to fade the automatic control raises the volume; when the signal increases the volume is lowered, so that better listening, close to the desired volume, results under variable conditions of reception.

Feedback control systems occur in the human body: the heartbeat rate and body temperature are two variables controlled in this manner. The method is also used in movement: when the hand reaches out for a glass of water a complicated series of operations begins—the will (the program) instructs the control (the brain) from which the hand receives its instructions; the eye senses the hand's position as it moves toward the glass and transmits the information back to the brain which then compares the actual position with the desired one and makes the necessary corrections; this series of operations is continuously carried out until the hand reaches the glass. (*See* CONTROL SYSTEMS.)

Scope of Automation.—It is often stated that automation can be applied only to large scale and repetitive operations. But this is not the whole story. A large output of identical articles can often be well-handled by highly mechanized systems. Variations from the norm occur gradually and over a period. Thus, inspection can take place outside the processing at suitable intervals and corrections made, say, at the end of a shift. The expense and complication of feedback control is not warranted in such a case. When, however, there are small quantities of a number of different articles of the same type which can be produced on the same machines or by the same process machinery, as is often the case in batch production, then automation can sometimes be used (the plates of a ship are a good example). With an automated plant all that is usually required is a change of program (the instructions to the plant). The process plant automatically makes the necessary adjustments. Examples of economic applications of automation to batch production are numerical control of machine tools, oxygen cutting (flame cutting) of ship plates, ready-mixed concrete and nonwoven fabrics.

The scope of automation may become as large in the area of batch production as it is thought that it will be in the realm of mass and continuous production. Indeed, the very versatility with which a system is endowed by automation may allow a wider variety of articles and products to be marketed economically and in this way increase the opportunities for batch production at the expense of mass production.

The application of automation is not confined to the factory and office; transport, banking, insurance, electricity supply, water supply, stock exchanges and medicine all supply examples of automation. In medicine an apparatus giving a continuous record of blood pressure in man over periods of several hours without the need for an arterial puncture has been designed and is in use. Blood pressure changes are followed during surgical procedure, during drug responses and during hypotension, and the infusion of hypotensive and hypertensive drugs is regulated to maintain the blood pressure at a predetermined level.



ELEMENTS OF AN AUTOMATED SYSTEM: (A) MANUAL CONTROL; (B) CLOSED-LOOP AUTOMATIC CONTROL; (C) MECHANIZATION (AUTOMATIC CONTROL); (D) AUTOMATION (FULL AUTOMATIC CONTROL)

Some Implications of Automation.—The difficulties that come about in endeavouring to define automation and the reason why some authorities dislike the word should now be clear. Most integrated systems of production, particularly if feedback control is used, could be described as automated systems. Automation makes a fresh approach necessary; indeed, some have gone so far as to describe automation as a "new philosophy of production." Be that as it may, there is no doubt that automation does seem to require a different and new consideration of management, labour,

unions and education. There are also social and economic implications. Before these matters are considered it is necessary to cite practical examples of automation at work in industry.

An automatic machine must be fed with raw material and the finished work must be removed. Manual adjustments usually must be made when the raw material varies, the tools wear or the specification is changed. Many of these operations require low mental decisions by the machine operator; he is the slave of the machine rather than its master and works to its tempo. With an automated machine system all these low-level mental decisions are undertaken by the control system; the operator is freed from the machine's dominance and can exercise a supervisory function. Then, however, decisions at much higher mental levels have to be taken, though not at frequent intervals, as, for example, when breakdowns or failures occur.

Automation then, is a way of putting power—usually electrical power—not only at the worker's elbow but also at his mental "elbow." It is a multiplier of man's physical and mental ability and in some cases a very large multiplier indeed; it is a unique means of multiplying his range of perception, speed of mental working and powers of co-ordination.

Effect on Management.—The effect of automation on management makes an interesting study. Traditional structures and organizations, it seems, are not suitable. The speeds of communication have to be increased; much more emphasis has to be placed on research (particularly production research), development and planning. Scientists and technologists have to be brought into the organization at all levels, both for specialist and general duties; various techniques such as market research and operational research become vitally necessary; and management training is important.

Effect on Labour.—Automation, by increasing the human span of work, makes for many more supervisory jobs and brings into being new skills. Men can tend to become isolated physically as well as mentally and the layout of people becomes as important as the layout of plant. Teamwork is essential, but individualism should be maintained, a most difficult result to achieve. The history of mechanization teaches that mass production, for instance, has created a multitude of jobs (compare the number that were employed in the making of horse-drawn carriages to the vastly greater numbers that are employed in motorcar manufacture). Automation brings products within the reach of the multitude and must therefore bring more jobs, but not necessarily the same type of jobs, into being. Problems of redundancy will arise, which should be of a short-term nature, but this of course is not much consolation to the individual who loses his job. Redundancy must be handled sympathetically, and proper planning to minimize disturbance should be undertaken. There is a pressing need for some trade unions to change their attitude toward retraining.

Social and Economic Aspects.—Automation will not necessarily bring in its wake greater happiness, but it will certainly bring a higher standard of living. More leisure will come about through shorter working hours and more people will have greater opportunities to pursue their interests and to travel. Heavy capital investment is involved, which implies a high level of saving. The economy will become tautened, or more highly tuned, and there will be a greater need for skilled direction.

AUTOMATION AT WORK

The following material has been drawn from a wide range of examples. Some of the illustrations may be on the border line of automation but they are included because they could take their place, say, in an automatic factory and they do indicate a definite trend.

Machine Tools.—The development of mechanization in industry often proceeded along simple lines. Each particular human job was mechanized, hence the mechanized span of work was equal to the human. The result is that the man is left as a linking device. The operator of a general-purpose machine tool frequently has to intervene in an otherwise automatic sequence and because of the shortness of the intervals he cannot be released for any other work. Programmed sequence control has been developed for work-holding, machine-slide movement, spindle feeds and speeds and similar motions which are usually under manual control. Electrical multibank stepping switches are used which signal a program through electrically operated air valves to air-operated cylinders controlling the machine. Besides the savings in costs, there are improvements in accuracy, finish and tool life. Another development which is becoming popular is the automatic replacement of worn-down tools by new ones; *i.e.*, automatic tool changing. There are also cutting machines which gauge each part as it is produced and compensate for tool wear by automatically resetting the cutting tool.

Punched tape, punched cards and magnetic tape can be used to position and operate a machine. Tape control on a nylon stocking knitting machine makes it possible to produce an almost infinite number of sizes with one tape. Changing from one size to another by the old method required from 10 to 30 min. shutdown time with the possibility of mistakes. A change by the new method takes but a few seconds and the control is remarkably flexible, easy to manipulate and saves time while increasing productivity.

The Drivmatic machine clamps the workpiece in position, drills and countersinks the rivet hole, injects the slug rivet, upsets the bottom of the slug, upsets the top into the countersink, mills the top head flush, unclamps the workpiece and resets itself for the next sequence. The sequence of operations and the operations themselves are automatically controlled by a tape unit using 35-mm. motion-picture film.

The same system of control is used for automatic co-ordinate setting on boring machines. Costly jigs are dispensed with, and much time is saved in setting up. The movements of the boring machine are operated by servomechanism (*q.v.*), and measuring devices record the relative movements between the respective parts of the machine and its bed.

Machine tool control by magnetic tape playback is another method which could have applications in a small factory and for batch production. A part is made manually and all the machine movements are recorded on a magnetic tape. When the tape is played back it repeats the operations and an identical part will be made, but much more quickly. The tape can be run any number of times.

Computer Control.—Numerical control of machine tools by computers has made great strides, particularly in the aircraft industry. Automatic machine tools are efficient and reliable when large quantities of identical parts are required, but changing automatic from one preset cycle to another is a long and expensive affair and would only be carried out for a long run. There are many instances when only a few parts are required and it is in such work that the computer-controlled machine is valuable. There are two types of computers used—digital and analogue. A digital computer operates with numbers represented in digital form, a digit being one of a definite set of symbols used to represent numbers. It is the digital computer which is used in electronic data processing. The analogue computer is based on an analogy of quantity; it deals with physical quantities and not numbers.

In a digital control system information from a drawing is put on a punched paper tape which is fed into a special type of computer which computes from the information the continuous path of the cutting tool. The output is recorded on a magnetic tape which is later fed into the machine-tool control unit when required. One computer services a number of machines. Tapes can be sent by mail, stored and used any number of times on future occasions, simply by replaying, if similar parts are wanted again.

For best results, the electronic control equipment and the machine tool must be designed together. The increase in productivity resulting from this type of control is remarkable. In machining one particular part, the time taken by the conventional method was ten hours. Using computer control, 92 min. were taken in planning time and the actual machining time was 14 min.

This method has been applied to the control of oxygen cutting of steel plate. When irregular shapes are required, as in shipbuilding, it has been the practice to make a wooden template and to follow its outline by hand control, a method which does not always give accurate results. Again, information is processed by

a special computer which then prepares a magnetic tape for use in the control console of the machine. With this tape the machine can automatically cut plates of complex shapes with great accuracy. This development has particular importance for fabricating steel plate and is a good example of automation applied to batch production. (*See* COMPUTER.)

Automatic Transfer.—The transfer machine line consists of a series of machines linked by mechanical handling equipment, the whole being centrally controlled. The parts are moved automatically from station to station along the line and have various operations performed on them such as broaching, drilling, milling and tapping. Automatic assembly operations are sometimes carried out by transfer machines. Usually no feedback control is employed, although various inspection procedures are carried out, for example, probes to indicate whether holes have been drilled; if the result is negative, then no signal is generated and the machine or one of its sections will be shut down. Tools have to be manually changed and there are various devices for indicating when this is necessary. One line, 350 ft. long, incorporates 181 electric motors totaling 996 h.p. and performs 555 machining operations on V-8 car cylinder blocks. It is controlled by one man.

Automatic transfer machines fall into three classes: straight-line, rotary and a combination of the two. The design of these machines differs in the United States and Europe. The U.S. favours highly specialized machines, whereas in Europe more flexible units have been developed with universal heads that can be modified with relative ease. To meet this need there is available a number of units or building blocks, which can be built up into quite complex machines. One such unit is an electrically driven indexing table which can undertake a series of up to 14 operations at once, including machining, forming, inspection and assembly. Another is an electromechanical unit head, with up to 30 spindles per head, which can be used in a single or multi-station indexing machine.

The electrical control of transfer lines is complex and a large number of switching units are required. In order to improve the reliability of the control system and to reduce maintenance, electromechanical switching is now tending to be replaced by electronic switching using cold-cathode tubes, magnetic amplifiers and solid-state devices. (*See* MACHINE TOOLS.)

Processing.—Many new methods of processing have been developed and are in use. It is interesting to note that a number are based upon principles which have been known for many years. These new methods are of particular importance in the application of automation in that they often lend themselves to a high degree of automatic control and are easily integrated into a production line. Dielectric heating, used in the furniture industry for gluing joints, enables new product designs to be made, eliminates the need for jigs and attendant storage space, and allows a much greater output to be obtained; increases of up to 300% are claimed. Induction heating is used for surface hardening, soldering, brazing and making glass-to-metal seals. Heating times are extremely rapid; for example, a two-station handling fixture connected to a 9-kw. generator hardens 38 tappet screws and 6 rocker pads in a minute (*see* HIGH-FREQUENCY HEATING). Soldering, brazing and hardening operations can thus be carried out automatically with machine-tool precision. Other processes of interest are electroforming, electropolishing, electro-spark machining, power spinning and powdered-metal forming.

Automatic Assembly.—Most products are assembled by hand, but the list of those which are automatically assembled increases year by year, though not as quickly as might be expected. Too often mass-produced articles fail or give trouble because of careless hand assembly. There are several reasons for the slow progress of automatic assembly. A product must be designed specifically for automatic assembly and must be accurately and consistently manufactured (otherwise it might jam the assembly machine). Parts easily grasped by human hands are not usually so easily handled by a simple mechanism. Many of the component parts made at present are not suitable for automatic assembly. Automatic assembly machines tend to be expensive and are somewhat inflexible; they are only economical if run at high outputs which are very large by present standards, but this situation could rapidly change with an increase in labour costs.

It is probable that outputs of individual manufacturers are not yet high enough to justify automatic assembly, but if any one manufacturing unit reached the break-even point for its adoption by expansion or amalgamation, it might soon force its competitors to employ this method, by amalgamation or other means. This argument is one that applies to other branches of automation, for there is no doubt that many of the new developments requiring large amounts of capital and having large outputs tend to create larger and larger manufacturing units.

Assembly machines can be built from some standard components, such as indexing tables and straight-line assembly machine bases, which are designed to provide basic movements for a wide variety of applications. They may be repeatedly used for different assembly operations by changing the working heads and resetting the controls.

One of the best examples of automatic assembly is provided by the use in the electronics industry of printed-circuit boards, component-inserting machines and dip-soldering techniques. The basic principle is relatively simple. The boards are moved by a special conveyor through a number of inserting stations, at each of which there is a component-inserting machine carrying a magazine of components. Each board stops and is clamped at a station and the inserting head then fixes a component to it; this procedure is repeated at every station with different components so that at the end of the line the board has a full complement of components. Automatic soldering is then carried out. This system is interesting for several reasons. It is highly mechanized, indeed automated, yet extremely flexible. Design of circuits can be changed easily and quickly. The components and their positions can also be changed. This example shows clearly that it is essential to redesign a product for automatic assembly; with the printed circuit, automation is simple, whereas it would be quite impracticable to mechanize the conventional method of wiring—the complex of wire and the soldering in, say, the older television set. Even if such a method had been developed it is unlikely that it would have been so flexible that circuit designs could be changed quickly. (*See* PRINTED CIRCUIT.)

Automatic assembly is being used in the production of subassemblies for 40-amp. and 60-amp. capacity contactors; the plant is made up basically of five circular indexing tables. In the motor-car industry, batteries, clutches, spark plugs, transmission couplings and door panels are among the components assembled in this way. At the Renault works in France a 17-station automatic transfer line is used for assembling rack-and-pinion steering boxes. A six-station unit inserts the studs, places the three main bearings in position on their seatings in the block, and threads the nuts on the studs and tightens them prior to fine boring. One operator does the work formerly done by six men.

The Bell Telephone company in Belgium has developed an automatic assembly line, which consists of a group of five machines, for the assembling, testing and packing of carbon microphones. The automatic machines are connected by synchronized transfer mechanisms. The assembling group is made up of 2 automatic machines, each having an indexing table with 12 positions that is driven by an air cylinder. The first machine assembles the front of the capsule, and the second the rear side. The company claims the following advantages for the system: (1) a shorter production cycle, so that exposure of the carbon chamber to dust is reduced to a minimum; (2) greater cleanliness of the product; (3) higher production; (4) better quality and greater uniformity of the product.

Ball pen refills are assembled on an indexing table at the rate of 60 a minute. The quality of the product has been improved and the saving in labour amortizes the cost of the machine in about 23 working weeks.

Industrial Finishing.—High costs are often incurred in finishing and painting; in the case of office furniture the cost per square foot may be much higher than that of the basic material. Automatic methods can play an important part in lowering these costs; electrostatic and hot-spray painting are examples. The present

trend is to work the finished material so that no finishing operations are required after fabrication and assembly. The idea is not new and has been used for many years in tin can making (see CANNING, COMMERCIAL). Plastic-covered steel sheet is already on the market; the adhesion of the coating to the base metal is so good that the material can be subjected to rather severe forming operations without delamination. Industrial finishing is used in the manufacture of office furniture, wall paneling, television cabinets, containers and cable trunking. There are distinct advantages in fabricating from pre-finished coated materials from the point of view of automation. The coating of continuous strips or sheets lends itself to automated working, whereas finishing articles of complex shape in their final form restricts its application. When the coating is carried out immediately after the final processing of steel, the cost of subsequent rust removal is eliminated.

Inspection and Testing.—Many different automatic inspection and testing machines are in use today. When the manufacturing process incorporates feedback, inspection machines may be a part of the control system. In some mass production industries, automatic machines are used to measure a number of dimensions of a part and then to sort the parts according to tolerance. Components are mated with others having suitable dimensions and a constant, close, predetermined fit is obtained.

A three-dimensional tape-controlled inspection machine has been developed. A measuring head with a stylus which can indicate movement in three dimensions replaces the cutting tool on a computer-controlled milling machine. The machine operates with a tape which so controls its movements that the stylus is always in contact with the surface being inspected. Any difference in shape from the programmed part as given by the tape causes the stylus to move and a recording is made.

Automatic machines are used for checking electronic circuits during manufacture. One machine with one unskilled operator handles over 100 different types of printed circuit board assemblies at a rate of about 3,000 a week. It performs up to 400 separate tests on each board, including continuity, leakage resistances, resistances, impedances and static voltages.

Electronic sorting by photoelectric cells of peas, lemons, coffee beans, nuts and other produce is in wide use. One installation of 140 machines can sort a total of 2,000 peas a second. The fully automatic sorting of coffee beans has allowed the upgrading of coffee, previously not considered suitable for export, to an exportable standard.

Nondestructive testing of material, which lends itself to automatic working, is making great strides because it is expensive, wasteful and unnecessary to use costly manufacturing facilities for processing parts from materials that are defective from the start. Jet and steam turbine blades, malleable castings, air frame parts, food, confections and ammunition are among the articles inspected in this way.

Instrumentation and Control in Process Industries.—Two major matters are delaying adoption of the computer-controlled process: lack of knowledge about particular processes and the theoretical relationship between all the variables involved, and lack of instrumentation for continuously measuring some of the process variables.

Continuous measurement of several physical quantities can now be made; *e.g.*, temperature, pressure, level, weight, flow and volume, together with viscosity, moisture content, conductivity, pH, liquid density, refractive index, specific gravity and, in some cases, chemical composition.

Much remains to be done. Not all analyses can be undertaken continuously, few analytical techniques are fast enough to apply in a continuous control system, and reliability is still generally not high enough. The infrared analyzer—fundamentally a simple optical system—has taken ten years of development by manufacturer and user before becoming moderately reliable. Reliability is of prime importance, because it is costly both to interrupt the process and to provide skilled maintenance. Many boilers have been working well below their maximum efficiencies because small users have found the maintenance of carbon dioxide analyzers and oxygen analyzers to be too expensive. Another major problem preventing the widespread use of process analyzers is the difficulty of securing a fair sample of a process stream in various types of plants.

As plants become increasingly complex and more and more process variables have to be measured, the necessity for checking a large number of measured and controlled values makes some form of data reduction necessary and automatic scanning desirable. Much of the information gathered is of no practical use except for research and during periods of disturbance or emergency. Data reduction, automatic monitoring and scanning of process variables are being used to an increasing extent. Such equipment in a power station will automatically and continuously scan, and record at very high speeds, readings of instruments measuring flows, levels, pressures and temperatures of boilers, furnaces and turbine units. The system will print out the relevant data at regular intervals, and will record and give warnings of any deviations from normal in the readings. It will also compute and record continuously the over-all boiler efficiency.

It is usually not the mathematical ability of digital computers that is required in industrial control applications but the ability to store and manipulate large numbers of observations. Computers are also needed which can receive information from any one of a large number of separate places, carry out the necessary calculations and issue the answer or order to one or more of a similar number of positions scattered around a plant in a matter of seconds, or, at most, a minute or two.

Several computers for on-line process control are on the market. One of the first installations controlled the polymerization stage of a petroleum refining process at Texaco's refinery in Port Arthur, Tex. Among the units available is an on-line process analogue computer. It employs time sharing of a minimum number of computer elements through the problem, by using the basic fact that in process control work the variables often change value relatively slowly. The computer accepts up to 48 inputs and computes up to eight outputs for control purposes. A complete scan is made in 25 sec. This is a useful unit for the piecemeal analysis of a plant, and also for subsidiary process control in large plants.

Two digital systems are also of interest. The Elliott system uses a central computer which controls the set points of individual controllers. Additional information not available from on-line instruments is fed manually into the system. Thus there are a number of local loops with one over-all loop. The Ferranti Argus process control computer can operate in this way or as a central controller. It is taking the place of conventional three-term controllers in a chemical plant; the outputs from thermocouples, pressure transducers and flow meters are fed straight into the computer and operated on in accordance with a program. Information is then sent out to various controlling devices. Between 200 and 300 variables are handled. In this instance, then, there is only one over-all loop. It is too early to prophesy which system will prove most efficient. Obviously the chances of complete plant shutdown are greater in the latter case. In this connection it is of interest to note Ferranti's statement that an Argus unit has run for 5,000 hr. on simulated control, with only four failures, all of transistors; but many years of operation may be needed before any true assessment is possible. Another development that has reached fruition is the sequence starting of plants. In the case of a power station boiler start-up about 700 variables are controlled by over-all regulation of three-term controllers.

These process computers are a new generation of machines. Among their features is a time-sharing facility which allows several different plants or processes to be handled concurrently. Even at this stage the application of a computer to plant control will allow much to be learned about plant characteristics, and hence will speed up this form of control as a result of monitoring process variables, continuous data collecting and logging, and performance computation. Between data-logging operations, the computer's general-purpose computing abilities can be used for statistical analyses, material and energy balances, and other complicated or tedious calculations.

The end-point optimizer or optimizing controller is another noteworthy development. This can be a relatively simple device

which searches continuously in an attempt to maximize the index that it is given as a measure of its success. The controller experiments by reading the index of performance, altering the set point of a conventional controller or similar plant setting by a small amount, allowing the plant to settle down and then finding whether the index has improved or deteriorated. From this result it decides its next move. The operation is repeated until the optimum index is achieved. This type of controller is the forerunner of a new type of computing system that will be able to learn or to gain experience. It will have a memory, and by trial and error within certain limits it will be able on its own to control a large plant, having in the learning process discovered what not to do in order to obey a program worked out according to a principle which simply says "optimize with respect to some particular characteristic." Computers are capable of following general instructions that are contingent upon the occurrence of particular events.

Centralized control implies the means of communication between the controller and both the controlled element and the sensing element. This is called "data transmission," and in factory or plant or between associated factories it is usually carried out with the aid of wires, though other methods are not precluded (microwave radio is used in a few cases). The subject is in its infancy. A simple equipment called a Multiplex indicating apparatus monitors direct-current signals which show the operating state of the unit being tested. Up to 12 units can be monitored simultaneously and instantaneously along a single pair of wires not exceeding 300 route miles. Thus great savings can be made in the complexity and cost of cabling.

Railways.—Railways throughout the world are beginning to apply automation and are drawing on experience gained with automatic control of industrial plants and with automatic control in other fields, as in the aircraft industry. A series of successful tests have been reported from the U.S.S.R. of new automatic control systems applied to a moving train. The equipment is in essence an electronic analogue computer designed to give optimal control of an electric locomotive running on a given track and following a given timetable. It limits the action of the driver to simple on and off operations of the automatic equipment during stops at the stations; he takes full control of the engine only in an emergency. The control commands are continuously fed to a system of servomechanisms in response to data gathered by sensing elements placed in strategic positions on the engine and track. The system operates the train with greater precision and economy than can even the most experienced driver. Results show a 7% saving in power consumption and a 15% increase in traffic.

The first fully automated underground railway in the world began operation in Hamburg in 1962. An electronic computer controls the whole system, which extends under the entire city. The control starts and stops trains, directs them to platforms, and changes speeds as necessary.

London Transport has installed a system of completely automatic operation of junctions on their underground railways. A progressive punched tape contains codes of train destinations and these arrange for the correct route to be set in a safe manner as a train approaches a junction. Previously these routes were set by signalmen located at junction signal boxes. Although automatic routing had not yet been applied to main-line railways in Great Britain by the early 1960s, amalgamation of signal boxes was being undertaken.

A different application of modern control techniques concerns the automatic operation of marshaling yards where freight cars (freight wagons) are collected and re-sorted. Such operations, when performed without automation, involve the use of a large amount of man power and consume a considerable amount of the total time freight is on the railways. In the most modern technique the cars are sorted by gravity in a hump marshaling yard (*see* RAILWAY: *Classification* [*Marshaling*] *Yards*) and on their way from the reception sidings down the gradient to the marshaling sidings the car speed is controlled by power-operated retarders. The routing of the cars is completely automatic from destination lists prepared beforehand. The running characteristics of cars in these yards are measured as they progress down the gradient and the requisite running distance into the sidings is given and corrected continuously; an analogue computer is used to calculate the correct speeds at which cars should enter the sidings. The speeds are controlled by retarders located on the track in accordance with the desired release speeds given by the computer. While the cars are passing through the retarders their actual speed is measured continuously by means of radar devices; this measurement and the calculated release speed are combined to control the retarder. These methods employ a minimum staff and result in speedier and safer handling of freight traffic. The yard at Margam in Wales can sort 4,500 cars and deal with 220 trains a day. Information on cars in reception sidings is given to the main control by radiotelephone and a tape, punched with holes to correspond to the information, is fed into a computer.

Air Transport.—Modern aircraft, particularly military planes, carry much equipment that is automated. A development of the automatic pilot can land an aircraft without the aid of a human pilot under conditions of zero visibility. Computers are being used for air-route traffic control; they relieve the operator of clerical detail involved in separating traffic in the air, carrying out this part of the work far more quickly.

Seat reservations in New York city are handled by a special central booking system. Ticket agents throughout the city can interrogate the machine to find out the available seats on particular flights. The vacancies are indicated, and if the agent sells the seats he communicates the details of the sale to the machine, which then subtracts the number from the inventory for that day's flight.

Flight simulators are used for aircrew training. A cockpit, identical to the one in the aircraft being simulated, is provided with a set of controls and instrumentation. The pilot's control movements are transmitted to an associated computer which computes the aircraft's response and displays the results on instruments. The pilot closes the loop by interpreting the information presented to him and making the necessary adjustments. A large number of different problems and flight conditions can be fed into the computer and so presented to the crew for their solution during the course of their mock flight. Such a simulator reduces the actual flying time required for general training purposes to about 25% of that normally required, thereby making large savings in money and freeing aircraft for more profitable duties.

Food Manufacture.—Automation has much to offer in food manufacture, including a guarantee of a high standard of cleanliness with the ingredients and products truly untouched by hand.

Biscuit and cookie manufacture provides some representative examples. Road tankers deliver flour, glucose, sirup and sugar to storage tanks, from which they are conveyed under automatic control to mixers and finally as dough to the ovens. Control is by a punched-card recipe system and a master control panel, by means of which the correct quantity and variety of flour is forwarded, while preset digital controls ensure the delivery of the required quantities of fat, sirup and glucose. Requests for a mix originate from the oven operator, who presses the appropriate button and so actuates the programmer which, in the event of more than one request at the same time, scans all the ovens in a set order until it finds one making a request. It then selects the recipe for that particular oven and initiates the supply of each ingredient to the receiver above the mixer. When weighing and dispatching operations are completed, the programmer hunts for another oven making a request.

In some cases there are added complications; in ice cream manufacture different mixes vary in content of butterfat and milk solids. The mix for a given formula must be recalculated daily—based on information from laboratory analysis—due to fluctuations in these contents. In one installation an analogue computer, separate from the control system, determines by simultaneous equations how much of each ingredient is required for a mix and digitally converts this information into pounds for translation by the batch-blending system. The manufacture of sugar, both cane and beet, and confections are other branches of the food industry which employ automation.

Mining and Quarrying.—A high level of mechanization has been employed for some time in the mining and quarrying indus-

tries, but developments involving automation have taken place in mining, *e.g.*, in the U.S.S.R. in the Donets basin, in Sweden at Kiruna and Malmberget (where there are large iron ore mines) and in Germany. In Great Britain a manless mine was being developed in the early 1960s. A nucleonic probe is fitted to the coal-cutting machine; this probe determines the thickness and undulations of the coal strata and directs the cutting head away from rock and other unproductive areas. The information obtained by the probe is transmitted to a control station from which the cutting machines are directed. The coal is carried on a conveyor to a loading head and raised to the surface without human attention. Hydraulic rams move the conveyor nearer to the coal face when the coal has been cleared. The roof supports automatically follow in a gradually advancing row, then cutting starts once more. Instruments on each support measure the vertical thrust against the roof and determine the exact position of the mobile supports. This data is required not only for controlling the sequence of operations but also for planning them in relation to strata formation.

Underground gasification of coal (burning the coal in its seam and piping the resultant gas to the surface) lends itself to the application of automation, but the method can only be used where conditions are suitable.

Textiles.—The mechanization of the spinning and weaving processes in the manufacture of cotton cloth took place at the beginning of the Industrial Revolution, but traditional designs of machinery are still in use. It is hard to conceive of any great increase in the application of electronics and automation to these machines; a large number of machines running in parallel means that even the introduction of a small item in one process results in possibly 100 or more pieces of apparatus being required. A new process for making nonwoven fabrics has been developed (such fabrics have their own characteristics that make them preferable for some uses and inferior for others in comparison with a spun and woven fabric). The new process readily lends itself to automation. Preparation machinery is still needed, but the large number of machines thereafter necessary in the conventional method are replaced by a single piece of equipment which takes the open and prepared fibres, turns them into a fabric by arranging them in the form of a mat and then bonds them chemically or physically so that they adhere together.

Retail Trade.—In the area of retail trade, automation is at present mainly used for inventory control or stock balances in department, chain and mail-order stores. In one store, all articles have information on their tags punched on one half and printed on the other. When a sale is made the printed half is handed to the customer as a receipt, and the perforated half is sent to a central processing department. Valuable information is quickly obtained, such as analyses of sales and stock positions. The system works at night, so that each morning buyers receive reports on the previous day's trading. The same system can work with information provided on printed or punched tape by special types of cash registers.

Warehousing.—Materials-handling studies have done much to change warehousing methods during the postwar years, and applications of automation now bid fair to make a further change. The driverless truck is a battery-electric tractor, electronically controlled to follow a continuous wire embedded in the floor. Trucks can be sent from one stopping place to any other station along the route, and routes can easily and quickly be changed. Safety devices are incorporated; for example, if a truck comes into contact with any object, it automatically stops. Driverless trucks have many uses in warehousing for the collection and distribution of goods as well as in other situations, such as railway terminal storage sheds.

It is possible to send some types of goods entirely through a complete warehousing cycle by mechanical equipment with electrical and electronic controls. Such procedure is economical only when there is sufficient activity among the stock items to keep the system fully utilized. Excellent opportunities often exist for introducing automatic handling and sorting without necessarily trying to make automatic the whole method of operation. A completely automatic installation might consist of conveyors from the receiving area feeding storage racks, which themselves would feed through selector gates onto other conveyors carrying the selected items down to the packing department. The whole installation would be under a master controller complete with memory unit. When goods are received, they would be recorded in the control and then routed to a storage point. An order for goods would be placed in the control unit, which would select the items from the storage racks and keep them together until they reached the packing department. No conventional paper records would be necessary, as the controller would maintain its own inventory.

In planning one punched-card automatic warehouse system to deal with orders throughout an entire sales area, it was decided that 72 of the most active items would be automatically handled. This resulted in 80% of the total volume being handled automatically. "Live" storage racks hold the 72 items, and the system can handle a variety of carton sizes ranging from 5 × 5 × 7 in. to 18 × 18 × 8 in. The automatic racks are manually filled. The control automatically reads, sorts and memorizes orders at a rate of 100 cards a minute; cartons are picked from the racks at the rate of 50 a minute, resulting in a total dispatching time of about one minute for the average order. The control ensures that cartons are discharged in a pre-established sequence which avoids pile-ups.

The Automatic Factory.—The ultimate object of automation is a state of affairs where the raw material enters the factory at one end and the product emerges at the other ready for dispatch, the whole production sequence being automatically controlled. Parallel and integral with the production would be automatic data processing (the equivalent of paper work) for ordering raw materials, scheduling, accounting and invoicing.

There are few automatic factories in operation, though one or two examples come very near to this description. One of the earliest was a plant designed and built by J. A. Sargrove in England in 1947 for making small radio receivers for the Chinese market. This project was abandoned for several reasons, among which were the collapse of the proposed market and the difficulties in obtaining consistency of results. The U.S. national bureau of standards developed project "Tinkertoy," a subassembly module processed from raw material, to meet the need for high-speed, high-volume low-cost production of electronic control equipment, suitable for defense purposes, available in an emergency, and on the assumption that there would be little or no skilled labour available.

Automatic plants that produce mixed and ready-to-use concrete are in operation. They are usually electronically controlled from a central panel, and manual labour is entirely absent.

A well-publicized example of an automatic factory is a plant in the U.S.S.R. which produces car pistons; it began operation in 1950. Aluminum ingots enter at one end and four sizes of piston emerge at the other, greased and wrapped. Apart from the initial loading of the ingots, all processes are automatic.

The Automatic Office.—The operations of an automatic office in commerce (for example, in banking, insurance and on stock exchanges), and in factories for production control, come within the scope of automation. The kernel is usually a data-processing system.

AUTOMATON: *see* ROBOT.

AUTOMOBILE, a self-propelled passenger vehicle designed to be operated on ordinary roads. In general, motor vehicles may be classified into several types, according to the service they render. Most numerous are the private passenger cars described in this article, intended usually to transport up to seven indi-

viduals; a subdivision of this type is formed by the so-called sports cars, which are designed primarily for speed and good road-handling characteristics, with passenger comfort a secondary consideration. Commercial passenger vehicles for carrying larger numbers of persons—buses and motor coaches—and commercial freight vehicles for carrying goods and materials are described in the article MOTOR TRANSPORTATION. Professional racing cars, some of them highly specialized and unsuited for ordinary road use, are the subject of AUTOMOBILE RACING.

This article is divided into the following parts:

An account of the industry to which demand for automobiles gave rise may be found in AUTOMOTIVE INDUSTRY, while the development of transport generally is described in TRANSPORTATION. (X.)

I. HISTORICAL DEVELOPMENT

Unlike many other major inventions, the idea of the automobile cannot be claimed for an individual. Perhaps because of man's universal concern with transportation, many individuals did simultaneous work on self-powered road vehicles. The idea surely occurred long before it was first recorded in the *Iliad*, where Homer (in Pope's translation) tells that Vulcan in a single day made 20 tricycles which

"(Wondrous to tell) instinct with spirit roll'd
From place to place, around the blest abodes,
Self-moved, obedient to the beck of gods."

Leonardo da Vinci considered the idea of a self-propelled vehicle. In 1760 a Swiss clergyman, J. H. Genevois, suggested mounting small windmills on a cartlike vehicle, their power to be used to wind springs that would move the road wheels. Genevois's idea probably derived from the Du Quet windmill cart of about 1714. Two-masted wind carriages were running in Holland in 1600 and for at least one of them a speed of 20 m.p.h. with a load of 28 passengers was claimed.

In April 1740, a carriage propelled by a large clock-work engine was demonstrated in Paris by its inventor, Jacques de Vaucanson. Later, toward the end of the 18th century, the idea of compressed-air engines became popular. William Medhurst patented an air engine in 1799, and suggested a grid of compressor stations to service vehicles propelled by it. Samuel Wright (1828) and William Mann (1829) worked along similar lines; Wright is said to have produced an air-powered road vehicle in 1832.

The air engine probably originated with Otto von Guericke (1602–86). Guericke invented an air pump, and was probably the first to make metal pistons, cylinders and connecting rods: the basic components of the reciprocating engine. The Dutch inventor Christiaan Huygens (1629–95) produced an engine that worked by air pressure developed by explosion of a powder charge. Denis Papin of France (1647–*c.* 1712) built a model engine on the vacuum principle, using condensation of steam to produce the vacuum.

A Belgian Jesuit missionary to China, Ferdinand Verbiest, is known to have made, in 1668, a model steam carriage using a principle that was suggestive of the modern turbine. Phillipe Lebon (1767–1804) patented a coal gas engine and was the first to mention electrical ignition. Isaac de Rivas (1752–1829) made and patented a gas-powered vehicle in Paris in 1807; his engine used hydrogen gas as fuel; the valves and ignition were operated by hand, and the timing problem appears understandably to have been difficult.

1. The First Automobile.—The Royal Automobile club of Great Britain and the Automobile-Club de France agreed on Nicholas Joseph Cugnot of Lorraine as the constructor of the first true automobile. Cugnot's vehicle was a large, heavy, steam-powered tricycle, and his model of 1769 was said to have run for 20 min. at $2\frac{1}{4}$ m.p.h. while carrying four people, and to have recuperated sufficient steam power to move again after standing for 20 min. One of the two models Cugnot produced is preserved in the Conservatoire des Arts et Métiers in Paris.

Most authorities are inclined to name Carl Benz (1844–1929) and Gottlieb Daimler (1834–1900) as the most important contributors to the gasoline-engine automobile. Benz ran his first car in 1885, Daimler his in 1886, both in Germany. There is no reason to believe that Benz had ever seen a motor vehicle before he made his own. Benz and Daimler had been preceded by the Belgian J. J. E. Lenoir (1822–1900) and the Austrian Siegfried Marcus, in 1862 and 1864, respectively, but neither Lenoir nor Marcus persisted. Benz and Daimler did persist, indeed to such purpose that the firm of Daimler-Benz could, in the 1960s, trace its origins back to 1895 and claim, with Panhard, to be one of the oldest automobile manufacturing firms in the world. Oddly, Benz and Daimler never met.

The four-stroke principle upon which most modern automobile engines work was discovered by a French engineer, Alphonse Beau de Rochas, in 1862, the year in which Lenoir ran his car from Paris to Joinville-le-Pont. The four-stroke cycle is often called the Otto cycle after the German Nikolaus August Otto (1832–1891), who designed an engine on that principle in 1876. De Rochas held prior patents, however, and litigation in the French courts upheld him. Lenoir's engine omitted the compression stroke of the Otto cycle: the fuel was drawn into the cylinder on the intake stroke, fired by a spark halfway through the stroke, and the burned gases exhausted on the next reciprocal stroke.

The idea for Siegfried Marcus's 1864 car came to him by chance. He was considering the production of illumination by igniting a mixture of gasoline and air with a stream of sparks. The reaction was so violent that it occurred to him to use it as a power source. His first vehicle was a cart carrying a two-cycle engine geared to the rear wheels without any intervening clutch. It was started by having a strong man lift the rear end while the wheels were spun. It did run, however, a distance of about 200 yd. (Marcus's second model, the 1874–75 car, was sturdy and well-preserved enough to make a demonstration run in the streets of Vienna on April 16, 1950, at a rate of 3 m.p.h. It had been bricked up behind a cellar wall in the Museum for Industry and Trade in Vienna in order to prevent its destruction at the time of the *Anschluss*. Marcus was Jewish, and the Nazi forces had specific instructions to destroy the machine and all copies of a 1924 brochure containing original photographs of the 1864 and 1874–75 models.)

In 1898 the Austrian Automobile club arranged an exhibition of motor cars and Marcus was a guest of honour. However, he denied interest in the entire idea of the automobile, calling it "a senseless waste of time and effort."

In 1823 or 1826 an English mechanical engineer named Samuel Brown drove a self-powered road vehicle up Shooter's hill in London, and he has sometimes been put forward as the first designer of an internal-combustion engine. An eye-witness account of Brown's drive exists and so do his patent specifications. His engine derived from the Newcomen condensing steam engine, had separate combustion and working cylinders, and apparently used carbureted hydrogen as fuel.

Léon Paul Charles Malandin produced a four-wheel vehicle with a four-stroke, two-cylinder gasoline engine in 1883, and he too is sometimes cited as the first to run an automobile with a true in-

ternal-combustion engine. However, his claim, like the others, falters before the continuity of the Benz-Daimler efforts.

2. The Age of Steam.—Before any internal-combustion engine had run, the followers of Nicholas Cugnot were on the road, notably in England, although the first post-Cugnot steam carriage appears to have been that built by Charles Dallery of Amiens, Fr., in 1790 and Amédée Bollée-Père (1844–1917) designed and built a successful steam coach. Steam buses were running in Paris about 1800. Oliver Evans of Philadelphia ran an amphibious steam dredge through the streets of that city in 1804. Less well known were Nathan Read of Salem, Mass., and Apollo Kinsley of Hartford, Conn., both of whom ran steam vehicles during the decade 1790–1800.

English inventors appear to have been in the van, and by the 1830s the manufacture and use of steam road carriages approached the status of a minor industry in the British Isles. James Watt's foreman, William Murdock, ran a model steam carriage on the roads of Cornwall in 1784 and Robert Fourness showed a working three-cylinder tractor in 1788. Watt was opposed to the use of steam engines for such purposes; his feelings were so strong that he inserted into the lease of a house he owned a clause stating that "no steam carriage should on any pretense be allowed to approach the house." Watt's low-pressure steam engine would have been too bulky for road use in any case.

Richard Trevithick developed Murdock's ideas, and at least one of his carriages, with driving-wheels 10 ft. in diameter, ran in London. Sir Goldsworthy Gurney, the first commercially successful steam-carriage builder, based his design upon an unusually efficient boiler. However, he could not be convinced that smooth wheels could grip a roadway, and so he arranged on his first vehicle for propulsion by iron legs digging into the road surface; this delusion persisted for some time and not only with Gurney. His second vehicle was said to weigh only 3,000 lb. and to be capable of carrying six persons. He made trips as long as 84 mi. in a running time of 9 hr., 30 min., and once recorded a speed of 17 m.p.h. (A rate of 32 m.p.h. was later claimed by two other builders, Nathaniel Ogle and William Summers.) To allay the public's fear of boiler explosions, Gurney designed a "drag," which was in effect a tractor or locomotive pulling one or more unpowered coaches.

Gurney equipment was used by Sir Charles Dance, who ran a regularly scheduled Gloucester-Cheltenham service of four round trips daily, at times doing the 9 mi., in 45 min. Between Feb. 27 and June 22, 1831, Dance's coaches ran 4,000 mi. on this route, carrying some 3,000 passengers. Dance and other steam-carriage operators had more than mechanical mischance to combat. The equipment was noisy, smoky, destructive of roadways and admittedly dangerous; hostility arose and it was common for drivers to find the way blocked with heaps of stones or felled trees. Finally, a minor accident (a broken axle) aroused so much public feeling that Dance's service was ended. Nevertheless, by 1829 some 20 steam carriages had been built, and many passengers carried, while the railways, although much used as freight movers, had not accepted a single paying passenger.

Walter Hancock of London dominated the most successful era of the steam coaches, from 1831 to 1838. He built at least nine vehicles, and they ran ambitious routes, including London-Cambridge. But by 1840 it was clear that the steam carriages had little future. They had had much to contend with, including the antimachinery attitude of the public and the enmity of the horse-coach interests, which resulted in such penalties as a charge of £2 for passing a tollgate that cost a horse coach only 3*s*. The government was of small help: a select committee of parliament recommended a research grant of £16,000 for Goldsworthy Gurney, but the treasury refused to pay it. The crushing blow was the Locomotive act of 1865, which reduced permissible speeds on public roads to 2 m.p.h. within cities and 4 m.p.h. in rural areas. This legislation was known as the Red Flag act because of its requirement that every steam carriage mount a crew of three, one to precede it by not less than 60 yd. carrying a red flag of warning. The act was amended in 1878 but it was not repealed until 1896, by which time its provisions had effectively stifled the development of road transport in the British Isles.

In addition to Murdock, Fourness, Trevithick, Gurney, Dance and Hancock, others who contributed to the steam-carriage movement were William Symington (1786); Thomas Allen (1789); Julius Griffiths (1821); David Gordon (1824); Sir James Anderson (1824); W. H. James (1824); James Nasmyth (1827); James Neville (1827); James Napier (1827); Onèsiphore Pecqueur (1828) of France; William Crawshay (1830); Francis Maceroni (1834); Thomas Squires (1834); F. Church (1832); Richard Roberts, probably the inventor of the differential gear, (1833); John Scott Russell (1833); Charles Dietz (1835) of France; and Harrison Dyer, Joseph Dixon and Rufus Porter of the United States.

3. Other Applications of Steam.—The decline of the steam carriage did not prevent continued effort in the field, and much attention was given to the steam tractor for use as a prime mover. Beginning in about 1868 the British Isles was the scene of a vogue for light, steam-powered personal carriages; if the popularity of these vehicles had not been legally hindered, it would certainly have resulted in the appearance of widespread enthusiasm for motoring in the 1860s rather than in the 1890s. Some of the steamcars were designed to carry as few as two people and were capable of speeds on the order of 20 m.p.h. Important figures in their development were the brilliant young inventors R. E. B. Crompton, Alfred Yarrow, J. B. Hilditch, and Isaac Watt Boulton. They had no lack of aristocratic patronage; the duke of Sutherland, the earl of Caithness and the marquis of Stafford supported them generously. The public climate remained unfriendly, however.

Light steam cars were being built in the United States, France, Germany and Denmark during the same period, and it is possible to argue that the line from Cugnot's lumbering vehicle runs unbroken to the American Doble steam automobile, the last example of which was made in 1926. The grip of the steam automobile on the American imagination has been strong ever since the era of the Stanley brothers (one of whose cars took the world speed record at 127.66 m.p.h. in 1906) and in the early 1960s it was estimated that there were still 7,000 steam cars in the United States, about 1,000 of them in running order.

4. Benz and the Gasoline Car.—Carl Benz was completely dedicated to the proposition that the internal-combustion engine would supersede the horse and revolutionize the world's transportation. He persisted in his efforts to build a gasoline-fueled vehicle in the face of many obstacles, including lack of money to the point of poverty and the bitter objections of his associates, who considered him unbalanced on the subject.

Benz ran his first car, a three-wheeler powered by a two-cycle, one-cylinder engine, early in 1885, a happy and triumphant day. He circled a cinder track beside his small factory, his workmen running beside the car, his wife running too, clapping her hands; the little machine made four circuits of the track, stalling only twice, before a broken chain stopped it. Even Max Rose, Benz's partner, whose money had made the car possible, conceded that he was mildly impressed; but, like Siegfried Marcus, he remained convinced to the end of his association with Benz that there was no future in the horseless carriage.

In the autumn of 1885, when Benz attempted a public showing of a slightly improved model, he forgot to steer and smashed it against the brick wall surrounding the yard of his own house.

Benz made his first sale to a Parisian named Emile Rogers in 1887. Later, however, the soundness of his design, and the quality and care that went into the material and the construction of his cars, bore weight, and they sold well. By 1888 he was employing 50 workmen to build the tricycle car; in 1890 he began to make a four-wheeler.

In his way, Benz was almost as dogmatic and reactionary as Marcus had been: he objected to redesign of his original cars, and some authorities believe that he was never really convinced that his original concepts had been improved upon.

5. Development of the Daimler.—Gunsmithing was Gottlieb Daimler's first vocation, and he showed marked talent, but he abandoned the trade to go to engineering school, studying in

Germany, England, Belgium and France. In Germany he worked for various engineering and machining concerns, including the Karlsruhe Maschinenbaugesellschaft, a firm that much earlier had employed Benz.

In 1872 N. A. Otto offered Daimler the position of technical director of his firm, then building stationary engines. Daimler was of notable utility to Otto during the next decade, when important work was done on the four-stroke engine. Daimler brought in several brilliant researchers, among them Wilhelm Maybach, but in 1882, both Daimler and Maybach resigned because of Daimler's conviction that Otto did not understand the potential of the internal-combustion engine. They set up a shop in Bad Cannstatt and built an air-cooled, one-cylinder engine. This was the first high-speed internal-combustion engine, for it was designed to run at 900 r.p.m., while Benz's first tricycle engine had operated at only 250 r.p.m. Daimler and Maybach built a second engine and put it into a wooden bicycle, which first ran on Nov. 10, 1885. The next year the first Daimler four-wheeled road vehicle was made: a carriage modified to be driven by a one-cylinder engine. (Daimler appears to have believed that the first phase of the automobile era would be a mass conversion of carriages to engine drive; Benz apparently thought of the motorcar as a separate device.)

Daimler's 1889 car was a departure from previous practice. It was based on a framework of light tubing, had the engine in the rear, driving by belt, and was steered by tiller. Remarkably, it had four speeds. This car had obvious commercial value, and in the following year the Daimler-Motoren-Gesellschaft was founded. The British Daimler automobile, for so long holder of the Royal Warrant, originated as a patent licensee, but later became quite independent of the German concern. (To distinguish machines made by the two firms in the early years, the German cars are usually referred to as Cannstatt-Daimlers.) The products of the Daimler-Benz company (the two firms were merged in 1926) are sold under the name Mercedes-Benz.

6. Early Efforts in the United States.—The Daimler-Benz claim to the invention of the automobile was attacked in 1895 when U.S. patent 549,160 was granted to George B. Selden as inventor of the automobile. Selden had filed on May 8, 1879, although he had not at that time built an automobile. He was successful in an effort to keep the patent pending for 16 years.

Some authorities are inclined to credit Charles E. and J. Frank Duryea as creators of the first American gasoline-powered automobile, in 1892–93. The idea for the car apparently originated with Charles Duryea, and the machine was built by Frank. The Duryea consisted of a one-cylinder gasoline engine, with electrical ignition, installed in a second-hand, $70 carriage. It might be said to have been assembled out of existing components. It ran first on Sept. 21, 1893; and J. Frank Duryea, driving a later model, won the first automobile race in America in which more than two cars competed, the *Chicago Times-Herald* race from Chicago to Evanston, Ill., and return, in Nov. 1895; the distance was 54.36 mi. and the total running time was 7 hr. 53 min. Duryea cars remained on the market until 1917.

However, the magazine *Antique Automobile,* after five years of investigation, announced its conviction that the Duryea had not been the first U.S. internal-combustion automobile, and that this distinction should be assigned to a car built in 1890 and run in 1891 by John William Lambert of Ohio City, Ohio.

The Duryea was certainly not the first U.S.-built road vehicle. A number of steam carriages had been built after Oliver Evans's first example. Sylvester Howard Roper, J. K. Fisher and Richard Dudgeon were familiar to people concerned with the steam carriage. Roper, in particular, appeared to be gifted: in March 1863, the magazine *Scientific American* described a test of a Roper vehicle that weighed only 650 lb. and achieved a speed of 20 m.p.h. Roper persisted, and in Sept. 1865 the publication *American Artisan* reported that he had reduced the weight of his carriage to 480 lb. Another American, Frank Curtis of Newburyport, Mass., is remembered for a special reason: he built a personal steam carriage to the order of a Boston man who failed to meet the payment schedule, whereupon Curtis made the first recorded repossession of a motor vehicle.

The U.S. patent office issued patents to F. A. Huntington in Sept. 1889 and W. T. Harris in April 1893 for three-wheeled, gasoline-engine carriages, and Gottfried Schloemer of Milwaukee, Wis., built a successful car in 1890, a machine that still exists. Henry Nadig, a machinist of Allentown, Pa., produced an automobile in 1899 that ran quite well despite its dependence on the most primitive possible carburetor: a wooden wick that delivered fuel to the cylinder by capillary attraction. Charles Black constructed a car in Indianapolis, Ind., in 1891, aided by Elwood G. Haynes, and Haynes followed the Duryea brothers with a gasoline car demonstrated in Kokomo, Ind., on July 4, 1894. Charles Brady King built a car in Detroit, Mich., the first of the millions to issue from the city, that first ran on March 6, 1896.

Ransom E. Olds, whose name survives in the Reo and Oldsmobile vehicles, was active in gasoline engine research in the 1890s, after initially being interested in steam: so were Alexander Winton and James Ward Packard. By 1898 there were more than 50 automobile companies in existence—although the name "automobile" had not been settled upon (also considered were motor fly, diamote, automotive, autometon, mocole, oleo locomotive, motorig, bolvite, locomotive car, autobaine, autokenetic, paramount and electrobat).

The 3-h.p., curved-dash Oldsmobile was the first commercially successful American made automobile: 425 of them were sold in 1901, 5,000 in 1904 (the model is still prized by collectors), and the firm prospered. Its prosperity was noted by others—from 1904 to 1908 241 automobile-manufacturing firms went into business in the U.S. One of them was the Ford Motor company, which was organized in June 1903 and sold its first car on the following July 23. The company produced 1,700 cars during its first full year of business.

7. Ford and the Automotive Revolution.—Henry Ford produced eight models before the Model T of 1908 with which his name is synonymous; these were the models A, B, C, F, K, N, R and S. They were not remarkable automobiles, but public response to the less expensive ones (the firm made some fairly costly cars at first) indicated the soundness of Ford's basic idea—to turn the automobile from a luxury and a plaything into a necessity. This, not mass production, was Ford's contribution to the world. Mass production was an old idea in Ford's time. In 1776 Jeremiah Wilkinson had invented the fixture or jig, a means of making identical parts in series, which is the root principle of mass production. Even before Wilkinson, in 1775, the French army had attempted to standardize musket parts. Ford's concept of the automobile as a necessity was much more important than the idea of mass production.

Ford also understood something that has defeated hundreds of automobile manufacturers and thousands of automobile dealers down the years: service. In the second year of his company's existence factory-trained mechanics were in the field.

Within two decades, the American automobile had won the revolution Henry Ford had begun. The country was on wheels, and the manufacture and sale of the automobile was a main prop under the U.S. economy. The closed car was no longer exclusively a rich man's possession. In 1920, most cars had been open models, the occupants protected from the weather by canvas-and-isinglass side curtains; ten years later Detroit was producing closed models almost exclusively.

The 1920s saw also the emergence of the great European producers, Austin, Morris, Singer, Fiat, Citroen, as the revolutionary Ford doctrine was carried forward on the continent and elsewhere. Universal motor transportation was a long way off, but the concept of the small car that arose in the Austin 7 and the Fiat Topolino, to name two of the descendants of Ettore Bugatti's tiny Bebe Peugeot of 1911, was to have a profound effect, culminating in the compact car revolution in the United States in 1959–61.

8. Age of the Classic Cars.—The decade 1925–35 was notable not only for the appearance of many new small automobiles: it also saw the building of many ultra-large ones. The years from 1925 to 1942 are cited by collectors of automobiles as the classic

years, a period which saw the rise of the luxurious fast motor car to a peak it seemed unlikely to reach again.

The first name in this field was Rolls-Royce, founded in 1904. Most Rolls-Royce chassis are designed for limousine and large sedan bodies, but the firm once made a car (called the Twenty) that would be judged compact today, and it has throughout its history produced fast models in addition to its regular line; *e.g.*, after World War II, the Continental, built under the Bentley label.

Other motorcars of this type included the Hispano-Suiza of Spain and France; Bugatti, Delage, Delahaye, Hotchkiss, Talbot (Darracq) and Voisin of France; the Duesenberg of the United States; the Horch, Maybach and Mercedes-Benz of Germany; the Belgian Minerva, and the Italian Isotta-Fraschini. These were costly machines, priced roughly from $7,500 to $40,000; fast, at 90 to 130 m.p.h.; as comfortable as the state of the art would allow; and limited in luxury only by the purse of the purchaser. The great custom coach builders of England who furnished bodies for Rolls-Royce machines were unruffled by the whims of their clients. They were prepared to satisfy any request, whether for upholstery in matched ostrich hide with ivory buttons or for a dashboard in rosewood carrying instrument labels in Old English script.

The most expensive standard automobile of which there exists convincing record was the Type 41 Bugatti, produced in the 1920s by Ettore Bugatti, an Italian of extraordinary gifts who built cars in France, most of them racing and sports types, from 1909 until his death in 1947. The Type 41 Bugatti, also called La Royale, was catalogued at a chassis price of $20,000. Only seven of the cars were built, and one of them, carrying a four-passenger convertible sedan body by a German coachmaker, cost $43,000.

The market collapse of 1929 sealed the doom of the really luxurious motorcar. After World War II even Rolls-Royce abandoned its long-held policy of chassis production only, and offered a standard sedan that could be bought straight off the showroom floor. Custom bodies were still available to Rolls-Royce purchasers through the old-line suppliers, of course. Throughout the rest of the world, save Italy, the custom body was a thing of the past. Even in Italy, most "one-off" designs were commissioned by automobile manufacturing firms, not, as in previous times, by individuals.

9. Developments After World War II.—The effect of Italian ideas on the world's automobile body designers was profound when manufacture began to be resumed in 1946. Pini Farina of Turin was best known of the coachmakers who established the characteristic Italian approach: grace, lightness in line and substance, and minimal use of decoration. Designs clearly derivative appeared everywhere, and manufacturers in France, England and the United States contracted for the services of Italian *carrozzerie*.

The trend toward the small automobile in the United States, clear, if not obtrusive, after 1932, was strongly accelerated by World War II. A leading factor was the return from duty in Europe of servicemen who had previously not known of the existence of the sheer variety of automobiles the world afforded. Particularly the sports car, designed for pleasure, not transport, was new to young Americans. The characteristics of automobiles like the British sports two-seater M.G., plus their availability at a time of short domestic supply, made them attractive, and the importation of European-made models into the U.S. increased rapidly. Automobile racing, which in the Vanderbilt Cup days around 1910 had drawn the biggest crowds in U.S. sports history, began to regain popularity, and by 1954 the *Wall Street Journal* reported that motor racing had become the no. 1 ranking American spectator sport.

While the size of the standard U.S. motorcar increased steadily from 1947 onward, and its design became ever more bizarre, the small segment of the population that leads in forming taste habits demonstrated strong preference for smaller cars, and for the comparatively demure Italian styling. Except for American Motors, successor to Nash and producer of the Rambler, the industry was slow to react. However, indications to be derived from the sale of Ramblers, Volkswagens and Renaults finally became quite clear and the major producers simultaneously undertook the production of smaller automobiles, generically termed "compact." At around 110-in. wheelbase, they were smaller than the less-big U.S. cars, bigger than the average European model. The first three on the market, Corvair (Chevrolet), Falcon (Ford) and Valiant (Chrysler), were instantly successful and began a predictable reduction in the sale of imported machines, which had peaked at around 500,000 units yearly. At first it seemed that even smaller models, of the size of the Volkswagen and Renault, might prove profitable to U.S. manufacturers, and two or three designs were on the drawing boards. U.S. buyers continued to show a preference for large automobiles, however, and many "compact" models grew bigger, heavier and more powerful, rather than smaller and lighter.

In Europe, a need for strict economy, the increasing high price of fuel and congested traffic conditions gave impetus to the development of a new series of ultra-light cars of simple specification and relatively inexpensive running costs. Many of these cars had two-stroke engines, such as the British Bond and the A. C. Petite. In Germany the Heinkel minicar was introduced, with a front-entry type of body, and the ingenious Messerschmitt tandem two-seater with a hinged airplane-type canopy. The B.M.W. Isetta, powered with a 245-c.c., four-stroke, single-cylinder engine with chain drive to the rear wheels, was one of the many varieties of four-wheeled designs introduced by various countries in search of economical road transport.

In France the 2CV Citroen was one of the most ingenious designs, particularly regarding suspension. First produced in 1948 as an economy vehicle, the relatively inexpensive 2CV was powered by a 375-c.c., horizontally-opposed, overhead-valve engine producing only 9 h.p. at 3,800 r.p.m. It gave a form of rather austere but economical motoring. The emphasis on economy, improved road surfaces, congested roads and the problem of parking directed manufacturers to a new phase in light car design. Bodywork radically altered under this influence, giving place to the modern stylized full-width envelope form of body that reduced both wind resistance and production costs.

Postwar expansion and experimentation produced many flurries of interest in new power sources. Gas turbines and free-piston engines were demonstrated. Improved batteries suggested the revival of the electric automobile (as improved burners and boilers suggested the revival of the steamer), and the practicability of the fuel cell was cited. Heat engines and air engines were redesigned. Of the new forms, only the gas turbine and the rotary-combustion (Wankel) engine saw actual use. The Rover company of England demonstrated a gas turbine automobile in 1950, and a decade later had the capability of entering the world market with it. The NSU Motorenwerke A. G. Neckarsulm in west Germany ran its Prinz model experimentally with a Wankel engine in 1961.

(K. W. Pu)

II. MODERN AUTOMOBILES: MECHANICAL OPERATION

1. Chassis.—The chassis of an automobile comprises the main structure of the vehicle, carrying the engine, wheels and axle assemblies, steering gear, transmission and gearbox and the suspension members. These components conventionally have been attached to a pressed-steel frame formed of channel or box-section members and usually reinforced by a central member. The frame serves as the structural foundation or backbone of the chassis. It unites and positions the various members, takes the torque reactions of the engine and driving axle, and receives the driving, braking and suspension forces from the wheels.

Since the mid-1930s, some automobile manufacturers have eliminated the chassis frame and made the body the major structural member of the vehicle. Instead of the body serving only as a passenger enclosure bolted to the chassis frame, its pressed-steel shell is provided with reinforcing braces that make it sufficiently rigid to resist the stresses applied to it. This unitized or frameless construction offers several advantages, and in the early 1960s there was a worldwide trend toward its adoption. The greater vertical height of the stress-carrying steel panels utilized

the steel more effectively, thus reducing the weight of material required. The sheer lines of modern automobile bodies are better adapted to load carrying than those of earlier years, and in a collision, because the points of impact crush with a delaying action, the rate of deceleration is reduced and the force with which the passengers are thrown forward is less. The greater torsional rigidity of the structure reduces noise and improves the functioning of the suspension system. A saving in cost of manufacture is possible, and the floor of the body can be lowered as required by modern styling.

Several objections originally were raised to the unit construction, but these have since been minimized. It was maintained that corrosion of the light metal body components, especially from salted highways, would seriously weaken the structure. This possibility led to the use of corrosion-resistant coatings and treatments that are formulated to provide the necessary durability. However, with frameless construction, repairs of collision damage must be made more effectively in order to restore the strength as well as the appearance of the damaged section.

Vehicle stability and control depend principally upon the weight distribution between the front and rear wheels, the height of the centre of gravity, the type of suspension system and whether front or rear wheels are used to drive the vehicle. Weight distribution is largely affected by the weight and location of the engine and transmission. Because there are both advantages and disadvantages in each possible arrangement of engine and transmission, no best possible layout is conceivable, but mechanical simplicity is greatly enhanced if the engine and the driving wheels are at the same end of the vehicle. Front-wheel drives and rear engines have always been in the minority, but the advent of lower body lines stimulated interest in both as means of eliminating the drive shaft and transmission humps in the floor of the car. Several European automobile manufacturers adopted front-wheel drive, and rear engines became common in the smaller European cars.

The development of aluminum engines and the use of air cooling helped to make practical the location of the engine at the rear of the car. One objection to water-cooled rear engines was the difficulty in operating the cooling system, because radiators function best at the front of the vehicle where the necessary air enters readily. Air-cooled engines present no special cooling problem when mounted at either front or rear.

Overconcentration of weight at the rear of a vehicle affects steering stability. This objection is met effectively by the air-cooled engine, especially if made of aluminum. Air-cooled engines in general are lighter than liquid-cooled engines of similar design and construction. The use of aluminum in air-cooled engines not only increases the weight advantage but also improves heat transfer from the cylinder walls to the outer surfaces of the cooling fins.

2. Engines.—The internal-combustion engine operating with gasoline as its fuel became the universally accepted source of power for propelling the automobile quite early in its development. This application placed demands upon the gasoline engine far more difficult to meet than those imposed by most other uses. Greater flexibility was necessary to permit the engine to operate over a wider range of crankshaft speeds; the weight of the engine had to be reasonable, and it had to be designed so it could be produced by economical mass production methods. Quiet operation also came to be demanded of the engine, along with compactness. All of these requirements dictated that the engine for an automobile of conventional size should have at least four cylinders of moderate capacity, with higher crankshaft speeds than for other applications.

The Increase in Horsepower.—One of the most conspicuous changes that took place in the development of the automobile, particularly in the U.S. models, was the increase in engine power. This increase was gradual at first, then became rapid in the period following World War II. The design improvements incorporated in the postwar engines utilized all of the known methods of increasing engine capacity.

Three factors determine the horsepower developed by an internal-combustion engine. The first is the effective average pressure in the cylinders during the operating cycle and is known as the brake mean effective pressure (b.m.e.p.). This pressure was increased by several design changes. Compression ratios were made higher, with accompanying increases in operating pressures and improved thermal efficiency. Because of higher efficiency, more of the energy released by combustion of the fuel was made available to react on the pistons and more work was done by each pound of fuel burned. The amount of fuel and air drawn into the cylinders was increased by enlarging the valves and increasing the amount they opened, by enlarging intake manifolds and carburetor throats, and by timing the valves to open earlier and close later. Refinements in combustion chamber design also improved combustion efficiency so that more of the energy in the fuel was utilized. These increases in b.m.e.p. could not have been accomplished without the contributions of the petroleum chemists and fuel-research engineers who developed higher antiknock quality fuels to meet the more severe fuel requirements of higher cylinder compression and greater charge density.

The second factor governing engine horsepower is the total swept volume, the volume displaced by all the pistons moving through the full length of stroke. This can be increased by enlarging the cylinder bore or by increasing the number of cylinders. Utilizing one or both methods, manufacturers produced a greater number of eight-cylinder engines and more engines with larger cylinder bore diameters.

The third factor determining horsepower is the average piston speed, which can be increased either by lengthening the stroke of the pistons or by increasing the rotational speed of the crankshaft. A considerable increase in crankshaft speed was offset in the new engines, to some extent, by shorter piston strokes, but the net effect was higher piston speeds. Shortened strokes resulted in larger cylinder bores in proportion to the piston displacement of the engines, with more room for the larger valves desired for improved cylinder charging. Shortening the stroke also reduced engine height, an important consideration with lowered automobile body lines. Stroke-to-bore ratios of less than 1 to 1 in post-World War II engines contrasted sharply with those of 1.5 to 1 commonly used earlier.

Shortening the Crankshaft.—Higher cylinder pressures and larger piston areas increased the forces transmitted to the crankshaft by the connecting rods and at the same time, higher engine speeds increased the dynamic forces acting on the crankshaft. The combined effect of these increases created a crankshaft vibration problem, a tendency for the crankshaft to twist and untwist cyclically under the alternating forces applied at the connecting rod bearings. This problem caused the virtual abandonment of the eight-cylinder in-line engine and the adoption of the V-8 engine for all piston displacements in excess of 240 cu.in. The long eight-throw crankshaft could not be made sufficiently rigid. The shorter V-8 crankshaft occupies less length in the automobile and is more resistant to vibration because of its greater lateral and torsional stiffness.

Return of Smaller Engines.—The smaller compact cars introduced by several U.S. manufacturers among their 1960 models returned engines of less than 100 h.p. to production. These were six-cylinder engines of from 140 to 195 cu.in. piston displacement, rated as low as 80 h.p. One of these was a rear-engine type, made largely of aluminum, with two banks of three horizontally-opposed cylinders. The typical standard size automobile engine in the U.S. at that time was a V-8 of large cylinder bore and relatively short piston stroke with a displacement of about 350 cu.in. Compression ratios for the larger engines were between 8½:1 and 11:1. Horsepower ratings were generally in the range from 250 to 350.

European Engines.—European automobile engines were of a much wider variety than those built in the United States, ranging from 1 to 12 cylinders with 18 to 302 cu.in. piston displacement, and with cylinder bores as small as 2.22 in. A majority of the models had four cylinders with less than 125 cu.in. displacement and horsepower ratings from 19 to 120. Several three-cylinder, two-stroke-cycle models were built in England, Germany and Sweden. All were in-line engines except the V-type models built

by five manufacturers and ten horizontally opposed two- and four-cylinder makes. Overhead camshafts were frequently employed. The smaller engines were commonly air cooled and located at the rear of the vehicle; compression ratios were relatively low.

The German Volkswagen was among the most popular European cars and had many features that contrasted sharply with American practice. The air-cooled engine, mounted at the rear, developed 36 h.p. at 3,700 r.p.m. Size of each of the four cylinders was 3.03 in. by 2.52 in. The short stroke and moderate rotational speed produced an average piston speed of 1,550 ft. per minute, which was only half that of contemporary American engines and contributed to the long life for which the VW engine was noted.

The cylinders in the VW engine were horizontally opposed, with the two on the left side displaced forward from those on the right, permitting a four-throw crankshaft to be used. The left front and right rear pistons moved in unison and oppositely from those in the right front and left rear cylinders. The two front pistons thus moved inward as the two rear ones moved outward, and the inertia forces produced by the reciprocating masses were almost completely balanced without counterweights on the crankshaft. The cylinders were finned to increase the heat transfer surface, and the valves in the cylinder heads were operated by rocker arms and push rods from a camshaft directly beneath the crankshaft. A radial-flow fan was mounted above the engine, belt-driven from the crankshaft, to supply cooling air to ducts surrounding the cylinders and to an oil cooler. A thermostatically-operated inlet damper varied the amount of cooling air in accordance with the cylinder temperature. An outlet butterfly valve permitted warm air to enter the passenger compartment in cold weather or to be discharged to the rear.

(*See* INTERNAL-COMBUSTION ENGINE; HORSEPOWER.)

3. Fuel.—Gasoline, or petrol, is essentially the only fuel used for automobile operation. The most important requirements of a fuel for automobile use are proper volatility and sufficient antiknock quality. The volatility is adjusted by the refiners so that sufficient gasoline vaporizes, even in extreme cold weather, to permit the engine to be started, but without being so volatile that vapour lock will prevent proper functioning of the fuel system at the highest outdoor temperatures encountered.

The antiknock quality is controlled by refining processes that produce compact, stable molecules instead of long, straight-chain molecules, as well as by the addition of antiknock compounds, principally tetraethyl lead. Antiknock quality is rated by the octane number of the gasoline and is the essential difference between the regular, premium and super premium grades offered for sale by the petroleum industry.

The octane number requirement of an automobile engine depends principally upon the compression ratio of the engine, but it is also affected by combustion chamber design and deposits formed on the chamber walls. Various additives intended to minimize the effects of deposits are used in most automotive gasolines. No advantage is gained by using a fuel of higher octane number than that necessary to eliminate objectionable knock.

(*See* also GASOLINE; FUELS: *Fuels for Light Internal-Combustion Engines.*)

4. Lubrication.—All moving parts of an automobile require lubrication. Without it, friction would increase the power consumption and also would soon destroy the parts. The lubricant also serves as a coolant, a noise-reducing cushion, and a sealant between engine piston rings and cylinder walls.

The engine lubrication system consists of an oil sump and a gear-type pump that delivers the oil under pressure to a system of drilled passages leading to various bearings. These include the crankshaft main bearings, the camshaft bearings, and the rocker shaft of the overhead valve mechanism. Drilled passages in the crankshaft conduct oil to lubricate the connecting rod bearings, and leakage from these bearings sprays oil up into the cylinder bores to lubricate the pistons, piston pins and piston rings. The spray also lubricates the cams and valve lifters. Usually, the oil passes through a paper or cotton-waste filter before it enters the distribution passages; bypass filters sometimes are used to receive a small stream of oil from the system continuously and return it to the sump after removing any solids.

Engine oils are identified by letters designating the severity of service for which the oil is suitable and by SAE numbers indicating the viscosity range. The letters ML are embossed on the containers of straight mineral oils intended only for light duty, MM for moderate duty oils that are mildly detergent and contain other additives, such as corrosion inhibitors, and MS for severe or heavy-duty oils that are highly detergent with large amounts of protective additives. The selection of the proper oil depends upon the conditions under which it will be used; continuous high speeds, heavy loads, frequent starts and stops, and engine components such as hydraulic valve lifters that are sensitive to oil condition, all require consideration.

SAE viscosity numbers range from 5W to 50, the viscosity or body of the oil at 210° F., increasing with the number. The W oils are light, cold-weather oils whose viscosity is measured at 0° F. Multi-rated or all-weather oils, such as 5W-20 and 10W-30, contain viscosity index improvers that reduce the loss in viscosity at higher temperatures. They meet the lower number specifications at 0° F. and the higher number at 210° F., making them suitable for use in summer or winter.

Wheel bearings and universal joints require long-fiber grease; other chassis joints require a soft grease that can be injected by pressure guns. Hydraulic transmissions require a special grade of light hydraulic fluid, and manually shifted transmissions use a heavier gear oil similar to that for rear axles. Hypoid gears used in most rear axles require oils that are compounded to resist heavy loads on the gear teeth.

(*See* also LUBRICATION.)

5. Cooling System.—Except for some of the very early models, the majority of automobiles have employed liquid cooling for their internal-combustion engines. Notable exceptions in the early 1960s were the German Volkswagen and, in the U.S., the Chevrolet Corvair, both of which had air-cooled, rear-mounted engines.

A typical automotive cooling system comprises (1) a series of channels cast into the engine block and cylinder head, surrounding the combustion chambers with a circulating stream of water to carry away excessive heat; (2) a radiator, consisting of many small tubes equipped with a honeycomb of fins to radiate heat rapidly, that receives and cools hot water from the engine; (3) a water pump, usually of the centrifugal type, to circulate coolant through the system; (4) a thermostat, which maintains constant temperature by automatically varying the amount of water passing into the radiator; and (5) a fan, which draws fresh air through the radiator when the car is at a standstill in traffic or moving slowly.

For operation at outdoor temperatures below freezing, it is necessary to add some compound to depress the freezing point of the coolant. Alcohol formerly was commonly used, but its relatively low boiling point makes it less desirable than ethylene glycol and other compounds. By varying the amount of additive it is possible to protect against freezing of the coolant down to any minimum temperature normally encountered.

As an added precaution, the engine block normally is provided with two or more expansion plugs; should the coolant in the block freeze, these are designed to give way, relieving ice pressure that otherwise might crack the block.

Compared with water cooling, air cooling offers the important advantage of eliminating not only freezing and boiling of the coolant at temperature extremes but also expensive corrosion damage to the cooling system. However, control of engine temperature is more difficult, and the engine temperature is more likely to vary with the outside temperature. Air-cooled cylinders operate at higher, more efficient temperatures, but compression ratios (with the same fuels) must be lower because combustion control is more difficult. In addition, it is more difficult to utilize engine heat to warm the car interior during winter.

With the aim of eliminating seasonal draining of liquid cooling systems, manufacturers in the later 1950s and early 1960s introduced liquid coolants intended to replace water-antifreeze mix-

tures. These solutions of deionized water and chemical additives had boiling points at about 240° and freezing points at about −40° F. They contained corrosion inhibitors that supposedly made it necessary to drain and refill the cooling system only once a year.

Other compounds under development in the early 1960s, some of which were organic silicates, contained no water and were permanent in characteristics. Such liquids permit the cooling system to be sealed and require no attention. The ultimate practicability of these permanent coolants will depend upon their specific heats. All previously known liquids with appropriate boiling and freezing points have much lower specific heats than that of water and are not as effective as engine coolants.

6. Electrical System.—Originally, the electrical system of the automobile was limited to the ignition equipment. With the advent of the electric starter on a 1912 model, electric lights and horns began to replace the kerosene and acetylene lights and the bulb horns. Electrification was rapid and complete, requiring only a few years to include most makes and models of cars. The electrical system comprises a storage battery, generator or dynamo, starting (cranking) motor, lighting system, ignition system and various accessories and controls.

Voltages at first were not standardized; 6, 12, 18 and 24 v. were employed before World War I. One U.S. manufacturer continued to use a 12-v. system until 1926, while all others who had used higher voltages changed to 6 v. after the war. Increased engine speeds and higher cylinder pressures of the post-World War II cars in the U.S. made it increasingly difficult to meet the high ignition voltage requirements. The larger engines also required higher cranking torque. To meet these two needs 12-v. systems had practically replaced the 6-v. systems by 1956.

The ignition system provides the spark to ignite the air-fuel mixture in the cylinders of the engine. In order to jump the gap between the electrodes of the spark plugs, the 12-v. potential of the electrical system must be stepped up to about 20,000 v. This is done by a circuit that starts with the battery, one side of which is grounded (earthed) on the chassis, leads through the ignition switch to the primary winding of the ignition coil and back to the ground through an interrupter switch or circuit breaker. The high voltage secondary terminal of the coil leads to a distributor that acts as a rotary switch, alternately connecting the coil to each of the wires leading to the spark plugs. The system consists of the spark plugs, contact breaker, coil, distributor and battery.

Power Sources.—The source of electrical energy for the various electrical devices of the automobile is a generator or dynamo that is belt-driven from the engine crankshaft. The generator is usually a two-pole, direct-current type with a shunt field controlled by a voltage regulator whose function is to match the generator output to the electrical load, and also to the charging requirements of the battery, regardless of engine speed.

A battery of the lead-acid type serves as a reservoir to store excess output of the generator by chemical changes in the sulfuric acid electrolyte and in the composition of the lead plates. Energy for the starting motor is thus made available as well as power for operating other electrical devices when the engine is not running or when the generator speed is not sufficiently high to carry the load. (*See* also BATTERY.)

High-wattage electrical loads, resulting from the addition of many electrical accessories, made commutation increasingly difficult in direct-current generators. Alternating-current generators, or alternators, with rectifiers were in use on buses where the electrical load had increased generator maintenance problems. In 1958 alternating-current generators with built-in rectifiers were introduced for passenger automobiles as a more practical way of providing for the high-wattage requirements.

The starting motor is a series-wound type that drives a small spur gear so arranged that it automatically moves into mesh with gear teeth on the rim of the flywheel as the starting motor armature begins to turn. When the engine starts, the small gear is accelerated above the armature speed and is then returned to its disengaged position, thus preventing damage to the starting motor from overspeeding. The starting motor is designed for high current consumption and delivers considerable power for its size for a limited time.

Lighting.—Headlights that satisfactorily illuminate the highway ahead of the automobile for night driving, without temporarily blinding approaching drivers, have long been sought. Early dimming devices of the resistance type that decreased the brightness of the headlights for passing gave way to mechanical tilting reflectors and later to double-filament bulbs with a high and a low beam.

The double-filament headlight unit, however, has only one of its filaments at the focal point of the reflector. Because of the greater illumination required for high-speed driving with the high beam, the lower beam filament was placed off centre, with a resulting decrease in lighting effectiveness. In an effort to improve all-round illumination, U.S. automobile manufacturers in 1957 began equipping their models with four headlights. In most instances the outer lamps were double filament types with a high-wattage low beam and a "soft" high beam for city driving. The inner lamps have a single filament high beam of high wattage that produces a spotlight effect. The low beam of the two outer lamps is focused slightly to the right and is used when overtaking or meeting other vehicles. The high beams of all four lamps are used on the open highway when there is no approaching traffic.

7. Transmissions.—The gasoline engine is inherently less suitable than the steam engine or the electric motor to propel a vehicle because it has no starting torque and must be set in motion before it can deliver any power. This characteristic necessitates some type of unloading and engaging device to permit gradual application of load to the engine after it has been started. The torque or turning effort that the engine is capable of producing is low at low crankshaft speeds, increases to a maximum at some fairly high speeds, and then decreases as the throttle is further advanced. Thus, the maximum or rated horsepower is attained only when the crankshaft is turning at its rated speed.

The specific fuel consumption of an automobile engine is best when the load on the engine is high and the throttle is nearly wide open. At moderate speeds on level pavement the power required to propel an automobile is only a portion of the power the engine is capable of developing in its upper range of speeds. Thus, under normal driving conditions at constant moderate speed, the engine may operate at an uneconomically light load unless some means are provided to reduce its speed and power output.

A speed-changing device known as a gearbox is necessary in the drive train that connects the crankshaft of the engine to the driving wheels. A device of this kind will permit the engine to operate at a higher speed when its full power is needed and to slow down to a more economical speed when less power is needed. Under some conditions, as in starting a stationary vehicle or in ascending steep grades, the torque of the engine is insufficient and amplification is desirable. Most devices employed to change the ratio of the speed of the engine to the speed of the driving wheels multiply the engine torque by the same factor that the engine speed is increased. Such devices are properly called torque converters, but are most commonly called transmissions.

Sliding-Gear Transmissions.—The simplest automobile transmission is the sliding-spur-gear type with three or four forward speeds and reverse. The desired gear ratio is selected by manipulating a shift lever. The early devices of this type required considerable skill on the part of the operator to shift the gears smoothly and without clashing the teeth. The shift from low to second gear was the most troublesome because this shift required that two gears, moving at different speeds, be slid sidewise into tooth engagement. This crudity in design was eliminated by the constant-mesh second gear in which the driven gear of the train is not keyed to the driven shaft of the transmission. Second gear is engaged by means of a toothed or jaw clutch, similar to that used to engage direct drive, arranged so that it can keep the driven gear from turning on the driven shaft.

Ease of shifting into second and high was further improved by the use of synchronizing clutches that engaged ahead of the toothed clutches and caused the two portions of the positive clutch to turn in unison before their engaging teeth touched each other.

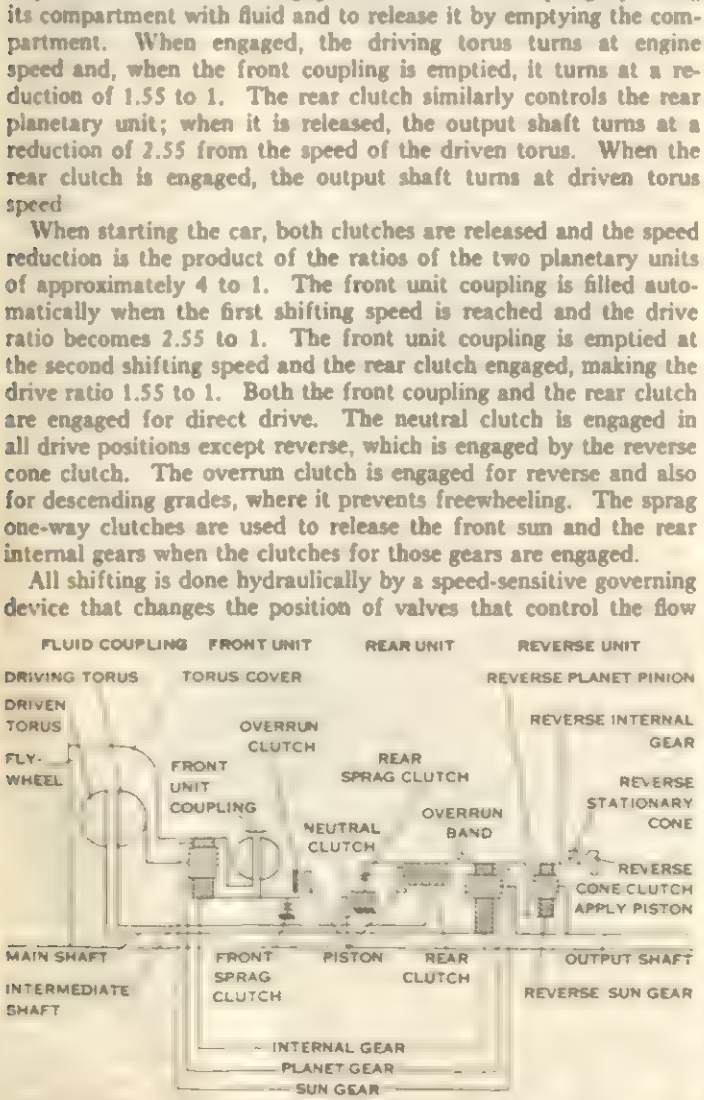
The blocker ring later prevented any possibility of the two members of the clutch contacting each other before their speeds were synchronized. The only difficulty remaining in the operation of the sliding gear transmission was the need for simultaneously operating the accelerator pedal, the clutch pedal and the gear-shift lever. This manipulation taxed the limited mechanical ability of many automobile drivers.

Automatic Transmissions.—All automatic transmissions may be classified into two groups, those employing a fluid coupling with automatically shifted planetary gear trains and those employing a hydraulic torque converter in various combinations with planetary gear trains. All of them provide manual selection of reverse and a low range that either prevents automatic up-shifts or employs a lower gear ratio than is used in normal driving. Grade-retard provisions are also sometimes included to provide engine braking on hills.

The first fully automatic transmission produced commercially (in 1939) for passenger cars was of the type using planetary gears for all torque multiplication. In 1956, after over 7,000,000 of these transmissions had been built, several changes were made to permit smoother shifts from one gear ratio to another. This transmission is shown in fig. 1 in its improved form. All torque multiplication is produced by the three planetary gear trains, each of which comprises a sun gear, a ring or internal gear, and a set of planet gears interposed between them. The front two planetary trains provide four forward speeds and the rear unit is the reverse gear. The front unit coupling is used as a clutch to lock out the front planetary unit that drives the driving torus. A provision is made to engage the front unit coupling by filling its compartment with fluid and to release it by emptying the compartment. When engaged, the driving torus turns at engine speed and, when the front coupling is emptied, it turns at a reduction of 1.55 to 1. The rear clutch similarly controls the rear planetary unit; when it is released, the output shaft turns at a reduction of 2.55 from the speed of the driven torus. When the rear clutch is engaged, the output shaft turns at driven torus speed

When starting the car, both clutches are released and the speed reduction is the product of the ratios of the two planetary units of approximately 4 to 1. The front unit coupling is filled automatically when the first shifting speed is reached and the drive ratio becomes 2.55 to 1. The front unit coupling is emptied at the second shifting speed and the rear clutch engaged, making the drive ratio 1.55 to 1. Both the front coupling and the rear clutch are engaged for direct drive. The neutral clutch is engaged in all drive positions except reverse, which is engaged by the reverse cone clutch. The overrun clutch is engaged for reverse and also for descending grades, where it prevents freewheeling. The sprag one-way clutches are used to release the front sun and the rear internal gears when the clutches for those gears are engaged.

All shifting is done hydraulically by a speed-sensitive governing device that changes the position of valves that control the flow



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 1.—DIAGRAM OF AUTOMATIC TRANSMISSION

of hydraulic fluid. The vehicle speeds at which shifts occur depend upon the position of the accelerator pedal, and the driver can delay up-shifts until higher speed is attained by depressing the accelerator pedal further.

Hydraulic Torque Converters.—The hydraulic torque converter is employed in all other automatic transmissions to provide a part of the needed torque multiplication. The hydraulic torque converter differs from the fluid coupling in having a stationary reaction member interposed between the impeller (driving torus) and the runner (driven torus); this serves to redirect the fluid so that it impinges on the vanes of the impeller as it returns from the runner The effect of the reaction member is to provide more torque tending to turn the runner than is applied to the impeller by the engine. It acts as a torque multiplier in the same fashion as a mechanical gear train.

Because of the need for a reverse gear and greater torque multiplication than the hydraulic torque converter provides, a planetary gear train is provided between the runner and the output shaft of the transmission. A type of compound planetary gear train with two sun gears and two sets of planet pinions has been designed that provides a low forward speed, a reverse, and a means of locking into direct drive. This unit is used with various modifications in practically all hydraulic torque converter transmissions. Control is by hydraulically engaged bands and multiple-disk clutches running in oil, either by the driver's operation of the selector lever or by a speed-sensitive governor.

Automatic transmissions not only require no skill to operate but make possible better performance than is obtainable with transmissions that necessitate the release of a clutch during gear shifts. Power is applied to the driving wheels continuously whenever the accelerator pedal is depressed and gears are shifted without closing the engine throttle or interrupting the drive.

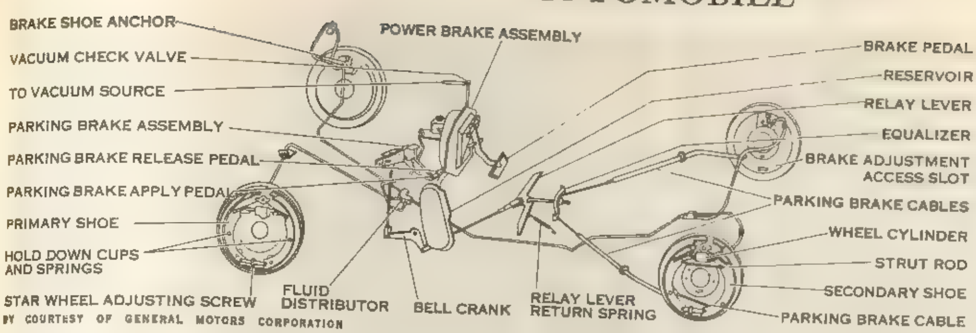
Small, low-powered European cars usually have manually shifted, four-speed transmissions Power-operated clutches are sometimes used in combination with preselective or semiautomatic transmissions. Fully automatic transmissions are used chiefly in the larger cars and they are more commonly stepped-gear devices than hydraulic torque converters. (*See* also POWER TRANSMISSION: *Hydraulic Transmissions: Hydraulic Coupling;* TORQUE CONVERTER; CLUTCH.)

8. Rear Axles.—Power is conveyed from the transmission to the rear axle by a propeller shaft and universal joints. As body lines were lowered progressively, the floor level came closer to the propeller shaft, necessitating floor humps or tunnels to provide clearance. The adoption of hypoid or offset spiral bevel gears in the rear axle provided an increase in this clearance by lowering the drive pinion below the centre of the axle shafts.

The ring gear of the rear axle surrounds the housing of a differential gear train that serves as an equalizer in dividing the torque between the two driving wheels while permitting one to turn faster than the other when rounding corners. The axle shafts terminate in bevel gears that are connected by several smaller bevel gears mounted on radial axes attached to the differential housing and carried around with it by the ring gear. In its simplest form this differential has the defect that one driving wheel may spin when it loses traction and the torque applied to the other wheel, being equal to that of the slipping wheel, will not be sufficient to drive the car. Several types of nonslip or torque-biasing differentials were developed to overcome this difficulty.

European manufacturers quite generally adopted a wide variety of articulated rear axles that provide individual wheel suspension at the rear as well as the front. Individual rear suspension not only eliminates the heavy rear axle housing but also permits lowered bodies with no floor humps, because the transmission and differential gears can be combined in a housing that is mounted on a rear cross member moving with the body under suspension spring action.

In some instances, European manufacturers use articulated or swing axles similar to American rear axles except that the tubular housings surrounding the axle shafts terminate in spherical head segments that fit into matching sockets formed in the sides of



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 2.—HYDRAULIC BRAKE SYSTEM

the central gear housing. Universal joints within the spherical elements permit the axle shafts to move with the action of the suspension springs. The gear housing is supported by a rear cross member of the chassis and moves with the sprung portion of the vehicle, as does the driveshaft. Other types eliminate the axle shaft housings and drive the wheels through two open axle shafts, each fitted with two universal joints. The wheels are then individually supported by radius rods or other suitable linkage.

The driving train for rear-engine cars is simplified by individually supported rear wheels in that a combined transmission and differential assembly can form a unit with the engine, and two short transverse driveshafts, each having universal joints at both ends, transmit power to the wheels. In this case there is no rear axle, as such, and the wheels are individually suspended much the same as the front wheels.

9. Brakes.—Most automobile brakes are of the internally expanding shoe type, in which two nearly semicircular brake shoes are pressed against the inner surface of a drum attached to the wheel. Until the 1930s, most brake systems were of the mechanical type, *i.e.*, foot pressure exerted on the brake pedal was carried direct to the brake shoes by a system of flexible cables. However, mechanical brakes are difficult to keep in adjustment so that equal braking force is applied at each wheel; and as vehicle weights and speeds increased, they demanded more and more effort on the part of the driver.

Mechanical brakes were almost universally supplanted, therefore, by hydraulic braking systems, in which the brake pedal is connected to the piston in a master cylinder. Steel tubing with flexible sections at the wheels leads from the master cylinder to the wheel cylinders. The wheel cylinders are located between the movable ends of the brake shoes and each is fitted with two pistons that are forced outward toward the ends of the cylinder by the pressure of the fluid between them. As these pistons move outward they push the brake shoes against the inner surface of the brake drum attached to the wheel. The differing diameters of the pistons in the master cylinder and wheel cylinders provides a hydraulic force multiplication that reduces the effort required of the driver.

Further increases in vehicle weights and speeds in the 1950s made even hydraulic brakes difficult for drivers to operate effectively, and many of the larger automobiles consequently were equipped with power brake systems. These are virtually the same as the hydraulic system except that the piston of the master cylinder is operated by a vacuum piston and cylinder instead of by the pressure exerted on the brake pedal (fig. 2). The master cylinder and vacuum power cylinder are formed in one unit as shown in fig. 3. When the driver starts to depress the brake pedal the valve plunger moves to the right in the piston and closes the atmospheric port. Further movement of the valve opens the vacuum port connecting the vacuum inlet to the cylinder chamber at the right of the piston. The vacuum inlet pipe leads to the intake manifold and, when the vacuum valve opens the port, a vacuum is formed on the right side of the power piston. Atmospheric pressure acting on the left side of the piston causes it to move to the right. The plunger in the master cylinder covers the compensating port and places the hydraulic brake fluid under pressure in the wheel cylinders. As the brake fluid pressure builds up, the rubber reaction disk compresses and pushes back the vacuum valve. If the pedal is not depressed further, the vacuum port will close and the brakes will be held in application until the pedal is released. The amount of brake fluid pressure depends upon how far the pedal is depressed; the driver feels a resistance to pedal movement proportional to the fluid pressure actuating the brakes. The force he must exert is much smaller, however, than is necessary with ordinary brakes, and no appreciable physical effort is necessary to apply the brakes fully.

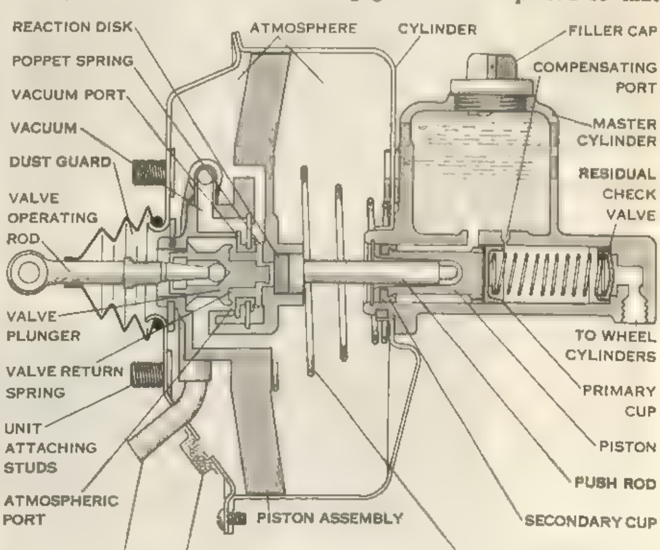
Overheating of the brake drums and shoes causes the brakes to fade and lose their effectiveness when held in engagement for a considerable length of time. This problem has been attacked by the use of aluminum cooling fins bonded to the outside of the brake drums to increase the rate of heat transfer to the air. Vents in the wheels are provided to increase the air circulation for cooling.

Disk brakes, originally developed for aircraft, have been fitted to some automobiles, but their greater cost has prevented widespread use. They are self-adjusting, and their ability to dissipate heat rapidly makes them practically immune to fading.

Parking brakes usually are of the mechanical type, applying force only to the rear brake shoes by means of a flexible cable connected to a hand lever or pedal. On cars with automatic transmissions, an additional lock is usually provided in the form of a pawl that can be engaged, by means of the shift lever, to prevent the drive shaft and rear wheels from turning. (*See* also BRAKE: *Motorcar Brakes.*)

10. Steering.—*Manual Systems.*—Automobiles are steered by a system of gears and linkages that transmits the motion of the steering wheel to the pivoted front wheel hubs. The gear mechanism, located at the lower end of the shaft carrying the steering wheel, is usually a worm-and-nut or cam-and-lever combination that rotates a shaft with an attached crank arm through a small angle as the steering wheel is turned. Tie rods attached to the arm convey its motion to the wheels. In cornering, the inner wheel must turn through a slightly greater angle than the outer wheel because the inner wheel negotiates a sharper turn. The geometry of the linkage is designed to provide for this.

When the front wheels are independently suspended, the steering must be designed so the wheels are not turned when the tie rods lengthen and shorten as a result of spring action. The point of linkage attachment to the steering gear must be placed so that



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 3.—CROSS SECTION OF POWER BRAKE MASTER CYLINDER

it can move vertically with respect to the wheel mountings without turning the wheels.

Power Steering.—The distribution of weight between the front and rear wheels of automobiles shifted toward the front as the engine and passenger compartment were moved forward to improve riding comfort and road handling characteristics. As the weight carried on the front wheels increased to more than half of the total vehicle weight, the effort necessary to turn the wheels in steering increased. Larger, heavier cars with wider tires and lower tire pressure also contributed to the drag between tires and road that must be overcome in steering, particularly in parking. It was originally considered satisfactory to limit the pull on the rim of the steering wheel to 30 lb. but, with an increasing number of women driving automobiles, this limit proved to be too high.

Considerable reduction in the work of steering resulted from increased efficiency of the steering gears and better bearings in the front wheel linkage. Additional ease of turning the steering wheel was accomplished by increasing the over-all steering gear ratio (the number of degrees of steering wheel turn required to turn the front wheels one degree about the spindle bolts). However, large steering gear ratios make high-speed maneuverability more difficult because the steering wheel must be turned through greater angles in negotiating curves. Steering mechanisms of higher efficiency are also more reversible, with the result that road shocks transmitted from the wheels must be overcome to a greater extent by the driver. This causes a dangerous situation on rough roads or when a front tire blows out, because the wheel may be jerked from the driver's hands.

Power-steering gear was the solution offered to solve the steadily increasing steering problems. Power steering was first applied to heavy trucks and military vehicles early in the 1930s, and hundreds of patents were granted for devices to help the driver turn the steering wheel. Most of the devices proposed were hydraulic, although some were electrical and others used power take-off from the engine.

Hydraulic power-steering systems are of two basic types, the integral and the linkage types. The integral type applies the hydraulic power assistance at the steering gear, whereas the linkage type applies the power direct to the linkage connecting the front wheels to the steering gear. The various systems also differ in the location and type of sensing device that controls the flow of hydraulic fluid to the power cylinder in response to the driver's movement of the steering wheel. All employ a pump driven by the engine to maintain a quantity of hydraulic fluid under about 1,000 p.s.i. pressure.

The sensing device is the most vital element of the power-steering system. This valve mechanism must allow the hydraulic fluid to flow into and out of the two ends of the power cylinder when necessary. The power cylinder is simply a hydraulic cylinder with a close-fitting piston attached to the steering linkage in such a way that the piston moves in one direction when the wheels are being turned to the right and in the opposite direction when they are being turned to the left. The cylinder is closed at both ends, suitable seals preventing the escape of fluid past the piston rod that passes through one or both of the end covers. The cylinder is always full of hydraulic fluid. If fluid is admitted to one end of the cylinder under pressure from the engine-driven pump and the fluid in the other end of the cylinder is allowed to escape to the fluid reservoir, a force equal to the product of the fluid pressure and the piston area is applied to the steering linkage. If the fluid connections are then reversed by the valves and fluid admitted to the opposite end, the wheels will be turned in the opposite direction. The function of the control device is to open a valve admitting fluid to the appropriate end of the cylinder and another venting fluid from the other end in response to a slight turn of the steering wheel by the driver. In effect, there are four valves opened and closed in pairs so that fluid is simultaneously admitted to one and released from the other of the two ends whenever the steering wheel is being turned. When the driver holds the steering wheel stationary, all four passages are closed and the front wheels are held in position.

The sensing device that actuates the valve mechanism usually employs the torque reaction to the turning of the steering wheel through a very small angle. In some systems end thrust on the steering gear worm causes a slight axial movement of the worm that operates the valve element. Others employ a torsion member that permits a slight twist in the shaft to which the steering wheel applies its motion and this angular displacement shifts the valve. The valve itself is usually a spool type, requiring a very small travel to open or close. The motion of the spool is usually axial, but there are also rotary valve types. The linkage system usually employs tension and compression in the linkage rod to actuate the valves.

An integral power-steering gear with the power cylinder built into the gear housing is shown in fig. 4. The nut portion of the circulating-ball steering unit is incorporated in a combined piston and rack that rotates the pitman shaft. Fluid is admitted to the left side of the piston for a right turn and to the right side for a left turn. The sensing unit is a rotary spool valve actuated by the twist of a torsion bar when the steering wheel is turned by the driver.

11. Suspension Systems.—The suspended portion of the automobile is attached to the wheels by elastic members designed to cushion the impact of road irregularities. The nature of the attaching linkages and spring elements varies widely among U.S. and European automobiles. Riding comfort and the handling qualities of the vehicle are greatly affected by the functioning of the suspension system. Mechanical simplification is gained by connecting the front wheels with a rigid front axle just as the rear wheels are connected by the conventional rear axle housing. Several important advantages, however, are gained by so-called independent suspension systems that permit the wheels to move independently of each other. The unsprung weight of the vehicle is decreased, softer springs are permissible, and front-wheel vibration problems are minimized. Independent front suspensions entirely replaced the rigid-axle type after World War II and numerous independent rear suspensions came into use on European cars. The first American production car to use an independent rear suspension was a 1960 model. Spring elements used for automobile suspension members, in increasing order of their ability to store elastic energy per unit of weight, are leaf springs, coil springs, torsion bars and air rubber-in-shear devices, and air springs.

Leaf and Coil Springs.—The leaf spring, although comparatively inelastic, has the important advantage of accurately positioning the wheel with respect to the other chassis components, both laterally and fore-and-aft, without the aid of radius rods, control arms or other linkages. For

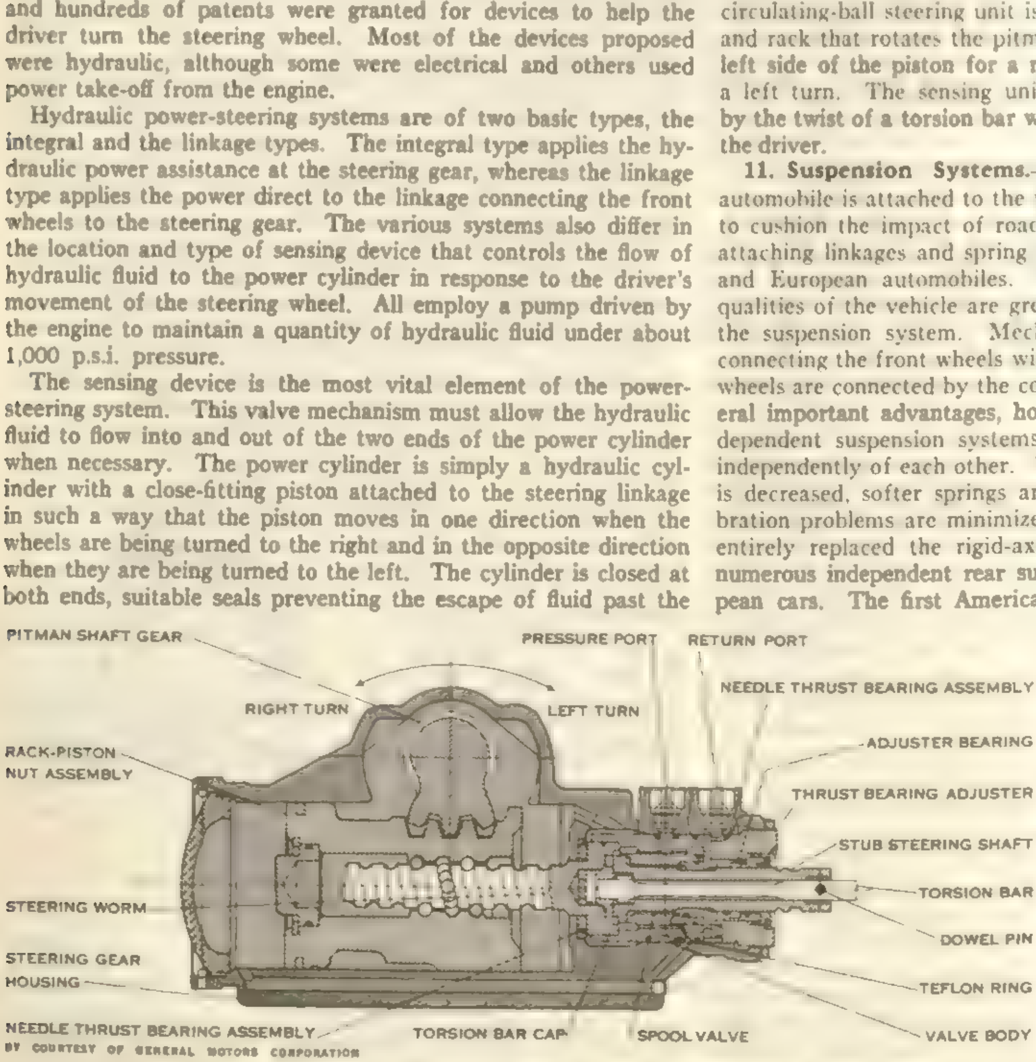


FIG. 4.—CROSS SECTION OF INTEGRAL POWER STEERING GEAR

this reason, semielliptic leaf springs were retained at the rear of most American cars until 1957, when coil springs with optional air springs were introduced by several manufacturers.

Coil springs met the requirements of independent front suspensions quite well and were adopted by most designers. One American manufacturer substituted torsion bar elements for the coil springs in a similar system of linkages.

Some cars equipped with rear leaf springs employ the Hotchkiss drive, in which the axle housing is rigidly attached to the spring seats so that the driving torque reaction, the brake torque, and the driving force are all imparted to the spring. Those using rear coil springs may have a torque tube enclosing the drive shaft and taking these forces to its point of attachment at the front of the axle housing. A diagonal transverse rod connecting one outer end of the axle housing to the chassis frame at the opposite side is provided to position the axle laterally. Other types with open drive shafts provide for these forces by radius rods and other linkages.

An important factor in spring selection is the relationship between load and deflection known as spring rate and defined as the load in pounds divided by the deflection of the spring in inches. A soft spring has a low rate and deflects a greater distance under a given load. A coil or a leaf spring retains a substantially constant rate within its operating range of load and will deflect ten times as much if a force ten times as great is applied to it. The torsion bar, a long spring-steel element with one end held rigidly to the frame and the other twisted by a crank connected to the axle, can be designed to provide an increasing spring rate.

A soft spring suspension provides a comfortable ride on a relatively smooth road, but the occupants will move up and down excessively on a rough road. The springs must be stiff enough to prevent a large deflection at any time because of the difficulty in providing enough clearance between the sprung portion of the vehicle and the unsprung portion below the springs. Lower roof heights made it increasingly difficult to provide the clearance needed for soft springs. Road handling characteristics also suffer because of what is known as sway or roll, the sidewise tilting of the car body that results from centrifugal force acting outward on turns. The softer the suspension the more the outer springs are compressed and the inner ones expanded by this force. Front-end "dive" under brake action is more noticeable with soft front springs.

Air Springs.—Air springs offer several advantages over metal springs. One of the most important of these is the possibility of controlling the spring rate. Inherently, the force required to deflect the air unit builds up increasingly with greater deflection because the air is compressed into a smaller space and greater pressure is built up, thus progressively resisting further deflection. The early air spring designs used a rubber bellows construction, basically like an accordion. The compactness required of modern automobile suspension units could not be had with this type. A piston and rolling diaphragm construction was found to meet the requirements. The piston is attached to the front wheel linkage or the rear axle housing by the bolt at the bottom, and the pressed-steel air dome is attached at its flange to the frame of the car. The laminated rubber diaphragm is molded with wire bead rings to permit sealed attachment at its outer periphery to the air dome and at the inside to the hollow steel piston. The piston is made smaller in diameter than the opening in the skirt so that the diaphragm can roll onto the cylindrical surface of the piston under compression and onto the skirt under elongation. Changes in alignment as the body of the car sways do not interfere with the operation of the spring unit.

Hydropneumatic Suspension.—A hydropneumatic or combination hydraulic-fluid-and-air suspension system was developed for the French Citroen model DS-19 car. The elastic medium is a sealed-in, fixed mass of air, and no air compressor is required. The hydraulic portion of each spring is a cylinder mounted on the body sill and fitted with a plunger that is pivotally attached to the wheel linkage to form a hydraulic strut. Each spring cylinder, of 1.375 in. bore, has a spherical air chamber about 4 in. in diameter attached to its outer end. The sphere is divided into two chambers by a flexible diaphragm, the upper occupied by air and the lower by hydraulic fluid that is in communication with the hydraulic cylinder through a two-way restrictor valve. This valve limits the rate of movement of the plunger in the cylinder, since fluid must be pushed into the sphere when the body descends and returned when it rises. This damping action thus controls the motion of the wheel with respect to the sprung portion of the vehicle supported by the spring.

The amount of hydraulic fluid in each spring unit is varied by front and rear leveling valves that transfer fluid to and from a central hydraulic system in which pressure is maintained by an engine-driven pump. These leveling valves serve to maintain constant clearance between the wheels and the sprung portion of the vehicle under varying passenger and luggage load.

A manual control is also provided that permits raising the vehicle to increase the road clearance when negotiating deep ruts. It also permits wheels to be lifted from the ground for tire changes by elevating the car, placing a support under either side and then allowing the unsupported side to descend by releasing the fluid pressure. The anti-roll or stabilizer bars, which limit lateral differences in spring displacement, then lift the wheels from the ground on the elevated side of the car.

The static pressure is about 480 p.s.i. in the front spring units and about 370 p.s.i. in the rear units. The softness of the suspension is intermediate between those of air and steel springs. The constant-clearance or level-ride feature is one of the major qualities of the hydropneumatic system.

AUTOMOBILE RACING. Automobile racing is the broad term for an amateur and professional sport of many categories: Grand Prix racing, sports car racing, production car (stock car) racing, endurance events, maximum-speed or maximum-acceleration events (drag racing), hill climbs, rallies and trials, etc. For the history of driving or touring by automobile for pleasure and the development of automobile clubs and rallies *see* MOTORING. Each racing category is composed of many classes and subclasses, depending upon the type and size of automobiles used and the course or track on which they may compete. There are also major differences between motor racing as practised in its two principal strongholds, the United States and Europe.

Wherever automobile racing is formal and official, it is conducted by organizing clubs. These are usually national organizations supervising racing, or a specified type of racing, in their home country. In the United States, for example, various organizations govern various kinds of racing: United States Automobile Club (USAC), National Association for Stock Car Auto Racing (NASCAR), Sports Car Club of America (SCCA), National Hot Rod Association (NHRA), etc.; in Great Britain the Royal Automobile Club (RAC) and the British Racing Drivers' Club (BRDC). The world governing body for automobile racing is the International Automobile Federation (Fédération Internationale de l'Automobile; FIA; founded 1904) at Paris. The FIA recognizes one national body from each member nation and sanctions events through the facilities of member clubs.

Pioneer Events.—Automobiles have been used for sport from the dawn of their history. Hardly was a self-propelled vehicle made for a utilitarian service in the 1880s than it was also tested

in competition of one style or another, often for the purpose of proving not only its speed but, more important in those pioneering times, its safety and reliability. By 1895, racing in a formal sense had begun. In the years that have followed, it has flourished in all the major western nations of the world, drawing huge spectator crowds and stimulating large investments of money by some manufacturers—who may have dual motivations: to use racing as a testing laboratory in which new and advanced designs are evaluated, and to earn popularity and good reputation as sales-promotion aids.

Though there had been a trial of horseless carriages on the road from Paris to Rouen, France, in 1894, the first real race was run from Paris to Bordeaux, France, in June 1895. It was won by a French Panhard automobile after more than 48 hours of driving at an average speed of 15 mph.

The next races, those from Paris to Vienna, Aus., and from Paris to Berlin, Ger., have justly been described as belonging to the heroic age. The crude vehicles traveled faster and faster through clouds of stinging dust on highways that were only imperfectly guarded. When passing another car, a driver could judge his direction and the approximate location of the road from what he could see of the treetops above the all-pervading dust. Tire trouble was common; dogs and farm carts ever-present dangers. Only men of pioneer calibre, aided by stouthearted mechanics traveling on the automobiles, could fight through to the finish against the troubles of untested mechanisms and the hazards of the road. (*See* also MOTORING: *Early Motoring*.)

The cars used in the early races were either those which were already in production or prototypes for future production, both submitted publicly to the most strenuous test possible. The races had therefore value as experiments leading to the evolution of better cars. This aspect made so great an impression on an enthusiastic U.S. newspaper publisher, James Gordon Bennett, that he offered a trophy to be won in a special race. The condition for the Gordon Bennett Çup was that a country might enter a team of three cars, every part of which, down to the smallest detail, had to have been made in that country. Thus was initiated a truly international series of six races, beginning in 1900.

By 1906, however, the large French automobile industry was no longer willing to be restricted to only three automobiles in the Gordon Bennett races and so organized the Grand Prix race with no limitations on the number of cars that might be entered from any nation. The first of these races was run in 1906 and it marked the end of the Gordon Bennett series; the French Grand Prix continued as a major automotive event.

While automotive events grew in numbers and popularity in Europe, interest in the automobile kept pace in the U.S. Most famous of the races held in the U.S. during the pioneer era of motor racing were the Vanderbilt Cup events beginning in 1904. These 300-mi. road races attracted some of the leading drivers and racing cars of Europe and were continued until interrupted by World War I in 1917. Two revivals of the Vanderbilt Cup races were held in 1936 and 1937. The American Grand Prize international road race was inaugurated at Savannah, Ga., in 1908 and continued as an annual event through 1916. It was won only once by an American car—a Mercer in 1914.

Also in this period, the first Indianapolis Speedway races were run in 1909 on a 2½-mi. macadam-surfaced track. In 1911 the surface was paved with brick and the first 500-mi. race was run, won by Ray Harroun in a Marmon averaging 74.59 mph.

Following World War I, the development of motor sport continued at a rapid rate. Almost every nation of Europe boasted its own Grand Prix event in addition to scores of lesser contests. As the automobile became man's most useful tool, so, too, it became one of his most popular instruments of sport.

Dangers.—Motor racing is a dangerous undertaking in all its forms. Although manufacturers and race promoters are usually reluctant to acknowledge the dangers inherent, spectacular and death-dealing accidents have marked the history of the sport from its earliest days. At various times, following fatal accidents involving either participants or spectators, the very continuance of motor racing has seemed to be in doubt because of public or official protests. For example, in 1903, during a race held on the roads between Paris and Madrid, several drivers and an uncounted number of persons were killed and maimed along the route. As a result the event was stopped short of its destination. This marked the end of the era of so-called point-to-point racing on open roads. During World War II, Benito Mussolini, appalled at the number of deaths caused during the running of Italy's Mille Miglia (thousand mile) race, placed a ban on future runnings of the event. This prohibition was ignored following the war, however, and the Mille Miglia continued to be run each year, usually with the loss of several lives. Finally, in 1957, an accident involving a car driven by the marquis de Portago brought death to the driver, co-driver, and several spectators and a final ban on the open-road race by the Italian government. In the United States, the death toll at the Indianapolis Memorial Day race has averaged more than one per year, yet the event is considered relatively safe by authorities. The most disastrous accident in the history of motor racing occurred in 1955, during the running of the famed 24-hour sports car event at Le Mans, France, when, after a collision, one of the automobiles hurtled into the crowd, killing 83 persons and injuring many more. For months, the entire future of racing was again in jeopardy, but eventually safety regulations were reviewed and strengthened and the sport continued. The opinion is often expressed by writers and close followers of automobile racing that this element of danger and the imminence of sudden death on the track plays no small part in the popularity of the sport with many participants and many spectators. Others disagree.

Midget Car Racing.—The sport of racing undersized cars emerged in the 1940s and quickly gained popularity. The cars must comply with rigid specifications. Wheelbases are 66 to 76 in. and tread widths 42 to 46 in. Racing at specially built tracks usually is conducted on a circuit plan providing series of races. The sport is supervised by the Midget Division of the USAC. (C. N. BA.)

Grand Prix Racing.—In the whole firmament of racing, Grand Prix events are the most elite. Grand Prix (*i.e.*, international formula) automobiles are commonly the ultimate in design, speed, horsepower—and romance. These are true racing cars in layman's language. In Europe, they are painted in national colours (British green, Italian red, French blue, German white, U.S. blue and white, etc.), entered by their manufacturers in events as teams (usually of two or three cars) and driven by the finest professional drivers. Races are held on closed circuits three or four miles to the lap; the total distance varying from 150 to 400 mi. Grand Prix cars have been constructed by Auto Union and Mercedes-Benz in Germany; by Bugatti, Delage, Gordini, and Talbot in France; by BRM, Lotus, Cooper, and Vanwall in England; by Alfa-Romeo, Ferrari, and Maserati in Italy—to name only a few. All modern Grand Prix cars conform to one of various formulas or sets of specifications which are laid down by the FIA and which govern the size, weight and type of vehicle permitted. In the late 1950s Formula I Grand Prix cars were limited to engine displacements of not more than 2,500 cc. without supercharger; not more than 750 cc. with supercharger. In 1961, Formula I was reduced to 1,500 cc. No supercharging was permitted. In 1966 this formula was changed to 3,000 cc. or 1,500 cc. if supercharged.

Based upon points earned in major Formula I events each year a driver is designated world champion. The qualifying events, called *grandes épreuves*, are customarily the Grand Prix of Monaco, Belgium, Netherlands, France, Great Britain, Germany, Italy, Mexico, South Africa, Canada and the United States (Watkins Glen; the Indianapolis 500—for track-type cars—no longer qualifies for championship points). In 1966 the FIA announced new rules, under which, beginning in 1967, drivers' performances would count in 9 out of 11 championship events. Points would be scored on the five best placings in the first six races of the season and on the four best places in the remaining five events. Competition for the title of world champion began in 1950 and it has been won by such famed drivers as Giuseppe Farina and Alberto Ascari of Italy; Juan Manuel Fangio of Argentina; Michael Hawthorne, Graham Hill, John Surtees, and Jim Clark

of Great Britain; Jack Brabham of Australia; and Phil Hill of the U.S. Prior to the establishment of the formal title many great drivers won international acclaim. The greatest of these was the Italian, Tazio Nuvolari; others of heroic stature include Rudolf Caracciola, J. P. Wimille, Luigi Villoresi, Richard Seaman, Achille Varzi, Raymond Mays, and Rene Dreyfus.

Sports Car Racing.—Although there are many conflicting definitions of sports cars, it is usually conceded that in normal production form they do not resemble Grand Prix machines. Whereas the latter is a single-seat design with spartan cockpit furnishings and utterly functional equipment throughout, the sports, or Gran Turismo (GT), car is usually a two seater, sometimes four, and is characterized by its nimble abilities (if not speed and power) together with general suitability for high-speed touring on ordinary roads. Unlike a Grand Prix car, it is intended to be a privately owned vehicle; also unlike its more exotic cousin, it is usually series-produced, seldom handmade. Some manufacturers of Grand Prix machines, such as Ferrari and Lotus, also make sports cars. Other makes include MG, Jaguar, Aston-Martin, Austin Healey, Triumph, Porsche, Lancia, Morgan, Chevrolet Corvette, and Cobra. Although not usually designed exclusively for racing, sports cars are nevertheless able racing machines and are often entered in competitions with their own kind. Some of the world's most famous races are sports car events and may even be designated as Grand Prix. (When the term Grand Prix is used in this context it does not refer to the type of car used but, rather, to the fact that the race is a major automotive event of the nation in which it is held.) The development of sports cars for racing, especially in such important events as the 24-hour endurance race at Le Mans (where the reputations of manufacturers are very much at stake) has brought about some sports cars that are, in reality, little different in their power and speed potentials from full Formula I machines. Based upon results attained each year in a select list of sports car races, a sports car championship is awarded. This list commonly includes: the Sebring 12-hour race, U.S.; the Monza 1,000 kilometres, Italy; the Nürburgring 1,000 kilometres, Germany; the Le Mans 24-hour race, France; the Targa Florio, Sicily; and the Tour de France. This championship was dominated by Italian Ferraris in the 1950s and 1960s although others, including British Aston-Martins and American Cobras, won many important races. The sweeping victory of Ford at Le Mans in 1966 broke Ferrari's domination. It should be noted that whereas the world championship in Formula I is awarded to a driver, the same title in sports car competition is awarded to a make of automobile.

Stock Car Racing.—Automobiles that are not racing models and not sports models usually are termed stock cars (U.S.) or production models. Production cars are the basis for some of the most widely attended and most commercially important events in the whole of motor sport. The origins of stock car racing are said to stem in part from the prohibition period in the U.S. when bootleggers, needing private cars of more than ordinary speed capabilities, tuned and altered ordinary passenger automobiles to suit their needs. Subsequently, these "hopped up" cars were often raced for pleasure. From these beginnings, an important branch of motor sport has grown. In the United States, largely because of the NASCAR, stock car racing flourished after 1949. Racing is conducted in several classes: grand national, modified, sportsman, etc., depending upon the type of automobile raced and the degree of modification allowed. Annual attendance at stock car racing events in the U.S. alone has been estimated at 10,000,000. Because results in these events are widely believed to have a powerful influence on brand preference among buyers of new cars, competition among manufacturers in the sponsorship of teams, engineers, drivers, etc., is often intense. Principal stock car events are held at Darlington (S.C.), Daytona (Fla.), and Atlanta (Ga.). The Monte Carlo (Monaco) rally and various national rally events in European countries fall in yet another category (*see* MOTORING).

Hot Rod Racing.—This subdivision of motor sport is largely confined to acceleration contests between privately designed and privately built automobiles which have been constructed along individualistic lines to provide maximum performance. Hot rods in various classes may also compete against time or distance in

speed and endurance attempts. A large number of national and international records, some previously held by large European or U.S. manufacturers, fell to hot rod builders and drivers in the period following World War II. Hot rodding as a hobby-sport suffered and survived an early period of bad public and press relations because of its associations with illegal street racing, but under the National Hot Rod Association (NHRA) became self-policing and widely accepted by youth organizations, police officials, service clubs, and automotive manufacturers.

No definition of a hot rod is universally accepted. These cars may be constructed of components from many makes of old or new automobiles; certain basic types are well-defined and recognized, however—such as roadsters, coupes and sedans, pickups, streamliners, etc.—depending upon style of body and intended use. Thus, a street roadster would be a high-performance automobile, yet suitable for general use; a streamliner, by contrast, is designed for top-speed performance at dry-lake or salt bed courses and would be unsuitable for any other purposes. All are usually constructed with strict regard for safety.

Drag Racing.—Conducted at specially constructed and often elaborately equipped strips all over the country, this is one of the most widely attended auto sports in the U.S. A drag, or acceleration test, measures the time required to cover a quarter mile from a standing start. The most specialized hot rods—so-called slingshots (in which the driver sits on an extension behind the rear wheels)—compete in this category. Some develop up to 1,000 hp. and complete the standing quarter mile in under 8 sec., reaching speeds over 200 mph. Standard production cars and sports cars may also compete in drag races.

Records.—Any of the automobiles heretofore described—Grand Prix, sports, stock, hot rods, etc.—may, in addition to participating in races or contests with their own kind, also make solo attempts against established time-distance records. Automobiles constructed solely for record attempts are likewise not uncommon. Records are established in both standing-start and flying-start categories and in both miles and kilometres. They may also be expressed in terms of distance achieved within a given period of time, the record for one hour, for example, being 190.68 mi. Engine size in cubic centimetres of cylinder volume is used as the basis for determining ten competition classes, designated A through J by the FIA. Thus, for example, ten separate records for the flying mile may exist at the same time, but greatest public interest is usually centred on the records in class A—cars with engines of unlimited size. In this class a world land-speed record of 394.2 mph set by Englishman John Cobb at the Bonneville salt flats, Utah, in 1947 stood until July 17, 1964, when Donald Campbell, son of a former British record holder, drove his jet-powered (rear wheels driven) "Bluebird" 403.1 mph at the Lake Eyre salt flats in Australia. This record for wheel-driven vehicles was broken by Bob and Bill Summers of the U.S. on Nov. 13, 1965, with 409.28 mph at Bonneville. Driving pure-jet-thrust vehicles, Craig Breedlove of the U.S. became the first human to be officially timed at more than 400, 500, and 600 mph, all at Bonneville. He set a record of 407.45 mph in a three-wheeled jet in 1963, sanctioned by the Fédération Internationale Motocycliste. The FIA qualified jet-thrust propulsion for the land-speed record, but still required that the vehicle have four wheels. In 1964 Breedlove in a four-wheeled jet was timed at 526.28 mph (in 23 days during October 1964 the records were: Oct. 2, Walt Arfons/Tom Green [U.S.], 413.20 mph; Oct. 5, Art Arfons [U.S.], 434.02 mph; Oct. 15, Breedlove, 526.28 mph; and Oct. 27, Art Arfons, 536.71 mph). Art Arfons set the record at 576.553 Nov. 7, 1965, and on Nov. 15 Breedlove pushed it past the 600 mark with an average of 600.601 mph for two runs through the measured mile.

Although international records may be set wherever official (FIA sanctioned) timing apparatus and observers are present, the salt beds at Bonneville are most frequently used for this purpose, particularly in the unlimited category. Daytona Beach, once the mecca of the record seekers, is extensively used in production-car tests, but does not offer the hundreds of square miles of ideal surface found at Bonneville.

AUTOMOTIVE INDUSTRY, the term usually applied principally to the manufacture of motor vehicles, although it also includes the manufacture of engine and body parts for motor vehicles. While the automobile is of European origin, the industry became heavily concentrated in the United States. From 1960 to 1965, for example, world automobile production approximated 14,288,000 vehicles annually, of which between 46% and 52% were made in the U.S. The economic importance of the industry was so great that automobile output became the principal index of U.S. business conditions and one of the important elements in the economic recovery of western Europe after World War II was the marked expansion of motor vehicle production. Along with the manufacture and sale of motor vehicles and parts the automotive industry brought into existence a substantial group of enterprises engaging in service functions: gasoline service stations, independent repair shops and dealers in automotive accessories.

The growth of the industry has been characterized by rapid technological changes both in the motor vehicle itself and in the techniques of production. Automobile manufacturing was, in fact, the first full-fledged mass production industry and it was the model followed by other manufacturers of durable consumers' goods (refrigerators, washing machines, etc.). The automotive industry also introduced changes in marketing practices, particularly in the American system of franchised dealers obligated to handle only one company's products. In addition, the industry underwent developments in business organization that had a striking uniformity in all the major automobile producing countries, namely, a progression from a large number of small firms to a small number of very large firms operating under conditions of limited competition.

ORIGINS OF THE INDUSTRY

Beginnings in Europe.—Like the motor vehicle itself, the automotive industry originated in Europe. The commercial manufacture of automobiles, as distinguished from the making of experimental models, was established in France and Germany about 1890. Carl Benz was advertising motor carriages in 1888 and the French firm of René Panhard and E. C. Levassor acquired the rights to manufacture vehicles using Gottlieb Daimler's patents in 1889. Daimler himself organized the Daimler-Motoren-Gesellschaft at Bad Cannstatt, Ger., late in 1890.

Interestingly enough, despite the undisputed primacy of Benz and Daimler as inventors of the gasoline automobile, France was the first to develop substantial commercial automobile production.

Daimler was successful in licensing his patents to manufacturers in other countries but he was not a major producer himself until his technical director, Wilhelm Maybach, designed the Mercedes in 1900 and the Daimler concern at the same time acquired a first-class business executive in Emil Jellinek. Benz likewise was a small-scale producer during the 1890s and the Opel firm, founded at Russelsheim, Ger., by Adam Opel, did not begin the manufacture of motor carriages until 1898.

On the other hand, Panhard-Levassor led the automotive field until 1900. The car that Levassor designed in 1891 was the prototype of the true automobile, instead of being just a "horseless carriage." It had the engine in front of, rather than under, the driver's seat, a sliding gear transmission and a differential gear with power transmitted to the rear axle by a chain drive. Armand Peugeot also began making automobiles with the Daimler engine in 1890. Then Count Albert de Dion and Georges Bouton, who had been building steam-driven road vehicles since 1883 with some success, turned to the development of a lightweight gasoline engine and became substantial manufacturers of motor tricycles. In addition the De Dion-Bouton engine was adopted by Louis Renault when he began to build automobiles in 1898.

Italy provided an early and important entry in the automotive field when the Fiat works (Fabbrica Italiana Automobili Torino) began to make motor vehicles at Turin in 1899.

Beginnings in Britain.—Britain had some promising experiments with steam-powered highway vehicles as far back as the 1830s, but its progress was seriously retarded by adverse legislation, culminating with the "red flag" law of 1865, which required all self-propelled vehicles on public highways to be preceded by a man on foot carrying a red flag. The real growth of the British automotive industry dates from the repeal of this law in 1896. At that time Frederick R. Simms organized a company to manufacture Daimler cars in Britain. F. W. Lanchester made the first all-British gasoline automobile in 1896; by 1900 such well-known makers as Riley, Napier, Wolseley, Sunbeam and Albion had appeared, followed by Vauxhall in 1904. Albion built only a few passenger cars before deciding to engage in the making of commercial vehicles exclusively.

The British automotive industry had the distinction of being the first to experience an attempt at monopolistic combination. The Daimler Motor company was owned by the British Motor syndicate, the creation of an energetic promoter named Harry J. Lawson, who hoped to control the industry through possession of the British rights to the Daimler and De Dion patents. The scheme collapsed in 1901 when the courts refused to sustain Lawson's claims.

Beginnings in the U.S.—In the United States, allowing for the manufacture of about a dozen cars by Charles E. and J. Frank Duryea between 1893 and 1898, commercial production of motor vehicles began in 1897 with the Pope Manufacturing company of Hartford, Conn., and the Winton Motor Carriage company of Cleveland, O. Two years later Ransom E. Olds organized the Olds Motor Works, followed by such concerns as Packard (1900), Cadillac (1902), Buick (1902), Ford (1903) and Maxwell-Briscoe (1903). The wagon manufacturing firm of Studebaker Brothers turned to automobiles in 1902.

Three Common Factors.—Several common factors emerge from this pioneering period of the automotive industry. Most of the early producers initially made automobiles as an offshoot of an existing enterprise, usually either the manufacture of machinery of some kind or of vehicles such as bicycles or carriages. Daimler, Benz, Lanchester and Olds were all engaged in manufacturing gasoline engines. Opel, Pope, Winton and Riley were bicycle manufacturers; William R. Morris and John North Willys were bicycle salesmen; Rover and Humber in Britain and Rambler and Peerless in the United States were popular names in bicycling before their makers turned to motor vehicles. Studebaker, as stated before, made wagons, Herbert Austin built his first car for the Wolseley Sheep-Shearing Machine company, Panhard and Levassor made woodworking machinery, James W. Packard manufactured electrical equipment, Henry M. Leland of Cadillac had a machine tool business, and the White Motor company grew out of the White Sewing Machine company. In other words, there was ordinarily a parent organization that could provide the initial capital and managerial and labour skill. The two most conspicuous exceptions to this pattern were Rolls-Royce and Ford. The former resulted from the association of C. S. Rolls, a wealthy motoring enthusiast, with F. H. Royce, an engineer, in a partnership that began by selling French cars and then decided to make its own. Henry Ford had two false starts before he founded the Ford Motor company in 1903 with financial assistance ($28,000) from a group of Detroit businessmen.

The second common factor was that to a very considerable extent these early automobile factories were predominantly assembly operations, especially in the United States. Independent supplier firms such as Briscoe Brothers, which converted a sheet metal business into a major producer of radiators, or the Hyatt Roller Bearing company made the components. Even engines were made separately; the Dodge brothers, John and Horace, got their start in the automotive industry by making transmissions for Olds and then engines for Ford. The assembly system was a method of financing as well as a technique of production. It became possible to go into automobile manufacturing with a minimum initial investment, since the "factory" was merely an assembly plant and the financing of production could be handled in the early stages by buying parts on credit and selling finished cars to dealers for cash.

Finally, the men who undertook to make motor vehicles had to decide whether the future lay with electric, gasoline or steam automobiles. While the electric automobile was very popular about 1900 because of its quietness and simplicity of operation, it was even then reasonably clear that battery capacity would limit the usefulness of the electric automobile. The failure of the steam automobile to remain in competition has been the subject of much speculation but no conclusive answer has been found. What is certain is that even the most successful manufacturers of steam highway vehicles, such as De Dion-Bouton in France, Thornycroft in Great Britain and White in the United States, switched to the internal-combustion engine by 1910. Only the twin brothers Francis E. and Freelan O. Stanley persisted with the manufacture of steam automobiles on a substantial scale until after World War I.

Troubles Over Patents.—The U.S. automobile industry, like the British, faced patent difficulties in its early years. The Pope Manufacturing company sold its motor carriage business in 1899 to the Electric Vehicle company, a syndicate whose initial intention was to manufacture and operate electric taxicabs. This company also acquired U.S. patent no. 549,160, issued in 1895 to George B. Selden of Rochester, N.Y., covering the basic features of a motor vehicle with an internal-combustion engine. Selden had filed his original application in 1879 and kept it pending for 16 years by methods then permitted by the patent law. The Electric Vehicle company's attempt to enforce Selden's patent resulted in an agreement among the principal U.S. manufacturers whereby the patent was to be administered by them, organized as the Association of Licensed Automobile Manufacturers (A.L.A.M.), for the purpose of promoting stability in the industry.

However some manufacturers, notably Ford, refused to recognize the validity of the Selden patent, and after an eight-year contest they effectively won their point when the U.S. circuit court of appeals held that Selden's patent was valid but only for cars with two-cycle engines. The long-range consequence was that in 1915 the automobile industry in the United States came to an agreement for cross-licensing patents that remained in effect until 1956. In addition the A.L.A.M. initiated a program, subsequently carried on by the Society of Automotive Engineers, for promoting technical standardization in the automotive industry.

MASS PRODUCTION

Demand Stimulates Production.—Few technical innovations have received as enthusiastic a reception as the motor vehicle. The demand for automobiles was so great that the fledgling industry of the 1890s became big business during the following decade. There was a rapid increase in the number of manufactur-

ing firms: the total number that entered the industry has never been calculated but we do know that 200 domestic makes of car had appeared on the British market by 1913 and 2,900 have been identified in the United States, most of them appearing before World War I. Nevertheless demand persistently exceeded the capacity of the industry to produce. This situation enabled manufacturers who were operating on slender capital resources to require cash payment from their dealers, because the dealers were clamoring for cars.

The vigorous demand for cars stimulated the manufacturers in two ways: first, there was constant pressure to improve methods of production so as to increase output; second, there was a realization that a vast potential market existed for low-priced cars. This condition applied most strongly to the United States, with its continental market area and high standard of living, so that American manufacturers were the first to adopt mass production techniques. While this development is indelibly and correctly identified with Henry Ford, there were other contributors. The basic techniques of mass production can be traced back at least to the work of the armories at Springfield, Mass., and Harpers Ferry, and to others at the beginning of the 19th century who applied machinery to the manufacture of interchangeable parts. The first low-priced automobile to be manufactured in quantity was the curved-dash Oldsmobile runabout—the original "Merry Oldsmobile"—which Ransom E. Olds put on the market in 1901. Production of this model reached a peak of 5,000 in 1904 but then Olds' stockholders decided to abandon it in favour of a heavier car. There were other attempts at low-priced cars along the same lines before Ford came into the field. A spectacular demonstration of interchangeability of parts in automobile manufacturing was provided in 1908 by Henry M. Leland when three Cadillacs were taken apart at the British Royal Automobile club's Brooklands track, the parts placed in a pit and scrambled, and 89 parts withdrawn from the pile at random and replaced from stock. The three cars were then put together again and made perfect scores on a 500-mile test run.

Ford's Moving Assembly Line.—None of this detracts from Ford's achievement. The lightweight roadster, like the curved-dash Oldsmobile, was unsuited to be the car for mass consumption because it was not built to stand up under hard usage. The secret of Ford's success was his realization that the first problem was to design an automobile that would be durable, capable of being used in city or country, easy to operate, and simple and inexpensive to maintain. He met these specifications with the Model T in 1908. Then he and his assistants went to work on the problem of manufacturing the car cheaply and in five years of experimentation evolved the moving assembly line. The new technique required a new factory to house it; complete assembly-line production of motor vehicles began in 1913 at the factory of the Ford Motor company in Highland Park, Mich., which had been designed and built for assembly-line operation.

The results were spectacular. The Ford Motor company made 15,000,000 Model T's before it discontinued the type in 1927; in 1920 the company was making half the motor vehicles in the world. The massive scale of Ford's operations was one of the principal factors in making Detroit the centre of automobile manufacturing in the United States. Ford's methods were widely studied and imitated and while no one else matched the phenomenal record of the Model T, the flow of low-priced cars increased markedly. Both William R. Morris (later Lord Nuffield) and André Gustave Citroën were inspired to do in their countries what Ford had done in his, although the advent of World War I delayed the realization of their ambitions.

Some other factors besides mass production and low price encouraged the widespread use of motor vehicles, conspicuous among them being improvements in the design and manufacture of tires and the introduction of electric starters in 1912. The latter, a joint achievement of the Cadillac Motor Car company and Charles F. Kettering, was particularly important in that it removed the most serious obstacle to the operation of gasoline-powered automobiles by women.

Effects on Other Industries.—Mass production of automobiles brought with it a number of far-reaching industrial consequences. The petroleum industry, naturally enough, was profoundly affected by the rising demand for motor fuels and lubricants and had to undertake both a vigorous search for new sources of crude oil and a virtual revolution in refining methods. The use of alloy steels in automobile manufacturing as a means of achieving strength without adding weight influenced the organization of steel production. For example, alloy steels were not manufactured at all in the United States until the growth of the automotive industry made it worthwhile to do so. In addition, the substitution of steel for wood in automobile bodies, which began about 1910 and became general practice in the 1920s, was directly responsible for the introduction of the continuous strip mill for making sheet steel in large quantities.

The manufacture of glass was similarly affected. When existing techniques proved inadequate to meet the automotive industry's requirements, the Ford Motor company in the early 1920s took the initiative in developing continuous-process manufacture of plate glass. The hazards of motoring led to the introduction of safety glass at the same time. Mass production also demanded quick-drying body finishes, and this need was filled in 1923 by the joint efforts of Charles F. Kettering and E. I. du Pont de Nemours and company. In addition the automotive industry became the largest user of machine tools, at the same time stimulating the development of increasingly elaborate and highly specialized tools.

There were indirect consequences also. Mass production by its very nature encouraged the growth of large-scale business organization, since it necessitated tremendous investment in plant and tools, and this investment in turn could be recovered only by a large volume of sales. After the introduction of the assembly line the number of new firms entering the industry declined appreciably and the smaller concerns found themselves either being merged into larger groups or squeezed out altogether.

CONCENTRATION AND COMBINATION

Since the United States offered the most favourable conditions for quantity production and sale of motor vehicles it was there that the first large-scale automotive enterprises came into existence. Henry Ford was the first figure to reach a dominating position in the industry, but the Ford story is exceptional. No other major automotive concern grew as a unitary organization concentrating on a single model.

The Creation of General Motors.—Far more typical was General Motors, which was formed in 1908, the same year Ford placed the Model T on the market. The founder of General Motors was William Crapo Durant, an energetic promoter who had made a fortune as a carriage builder and then in 1903 became interested in the Buick Motor Car company, which had an excellent design but was faltering in production and marketing. Under Durant's management the Buick became one of the leaders on the American market. Durant then became convinced that success in automobile manufacturing required an organization large enough to control its parts suppliers and to offer a variety of models, so that a bad year for any model would not have to mean disaster. He and Benjamin Briscoe, who had preceded Durant as Buick's backer and then produced the Maxwell-Briscoe, tried to consolidate the principal U.S. automobile companies, including Ford, but failed.

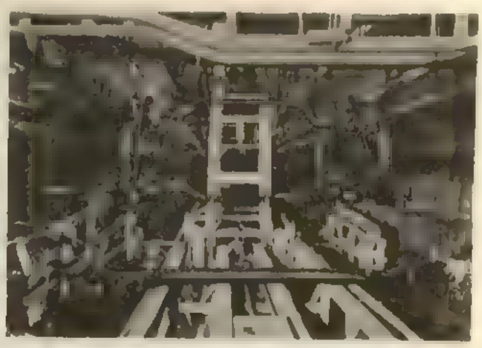
Durant and Briscoe then went their separate ways. Briscoe organized a combination called the United States Motor company that went into receivership in 1912 and was subsequently reorganized as the Maxwell Motor car company. Durant chartered the General Motors company in 1908, with Buick as its base. During the next two years he added Cadillac, Oldsmobile, Oakland and a variety of lesser automobile and parts manufacturers. Some, like the Champion Ignition company, which Durant himself financed to manufacture the porcelain spark plug designed by Albert Champion, were valuable properties; others, however, were speculative, and in 1910 General Motors was faced with insolvency.

The company was saved by a banking syndicate headed by James J. Storrow of Lee, Higginson and company. Durant was forced out and Charles W. Nash became president of Genera

Motors. Storrow also brought Walter P. Chrysler into the organization, first as Nash's assistant and then as president of Buick.

Meanwhile, Durant had joined forces with Louis Chevrolet to produce a low-priced car of the latter's design. The Chevrolet did so well that Durant was able to use its profits to buy back his control of General Motors. This he accomplished in 1916, with financial support from du Pont interests. When Durant returned to power, Storrow and Nash left General Motors and bought control of T. B. Jeffery and company, manufacturer of the Rambler car. This company they reorganized under Nash's name.

Durant's activities included the formation in 1916 of a combination of parts manufacturers under the name of United Motors, the most significant acquisitions being the Hyatt Roller Bearing company and its president, Alfred P. Sloan, Jr. and the Dayton Engineering Laboratories company (Delco), which brought Charles F. Kettering into the General Motors fold. In 1918 a new General Motors corporation absorbed United Motors and also ended the anomalous situation whereby Chevrolet controlled General Motors.



BY COURTESY OF GENERAL MOTORS CORP

Steps in final assembly of a car: (top left) steel top being placed on body; (top right) frames on chassis assembly line; (bottom left) body being placed on frame; (above) attaching wheel; (right) finished cars loaded on railway cars

The second Durant regime was in many ways similar to the first. There was continued expansion, some wise and some not. Durant himself devoted much of his attention to the stock market and both Chrysler and Sloan became disturbed by the lack of an effective administrative organization. Chrysler's disagreements with Durant led to the former's resignation. The panic of 1920 came close to ruining Durant; in order to avoid possible serious trouble for General Motors the du Pont family rescued him from his speculative involvements but insisted that he leave the company. P. S. du Pont assumed the presidency temporarily and turned it over to Sloan in 1923. Durant himself made still another effort in the form of a combination called Durant Motors but this lasted only until the economic crash of 1929.

Other U.S. Combines.—Still another promising automotive empire was the one built by John M. Willys. Willys began his career as a bicycle and automobile dealer and found himself in the manufacturing end of the business when he took control of the moribund Overland company in 1907 in order to keep it operating so he could secure delivery of cars he had ordered. The Overland became a popular low-priced car and Willys gradually acquired control of other automotive concerns, most of them loosely organized as parts of the Willys corporation. Like Durant, Willys was caught in the 1920 depression and while he was able to stay in business, he no longer had the prospect of rivalling General Motors or Ford.

Studebaker offers an example of a combination created by a company that made a conscious decision to add motor vehicles to an existing carriage and wagon business; in 1900, in fact, Studebaker was the world's largest manufacturer of horse-drawn vehicles. Shortly after the turn of the century the company began making automobiles, but it also undertook to employ its extensive distributing facilities to market cars manufactured by others. In 1909 Studebaker contracted to sell the EMF car (Everitt-Metzger-Flanders), but when this arrangement proved unsatisfactory, Studebaker bought out its affiliate and consolidated its enterprises in 1912 as the Studebaker corporation. The fact that the financing of this transaction was handled by J. P. Morgan and company, at about the same time Lee, Higginson and company was reorganizing General Motors, is clear evidence that in the U.S. the automotive industry had successfully emerged from its infancy.

THE MATURING OF THE INDUSTRY

Wartime Growth.—World War I stimulated the growth of the automotive industry by providing a heavy demand for motor vehicles and other commodities that automotive plants could produce. The potentialities of the motor vehicle for the transport of troops and supplies were appreciated if not fully developed. Apart from the need for strictly military vehicles such as tanks and armored cars, the principal demand was for trucks. Automotive factories also made aircraft engines and parts as well as shells, gun mounts and a variety of other military equipment. Among the European belligerents production of cars for civilian use was curtailed fairly early in the war; the U.S. automobile industry, however, functioned without appreciable limitation until 1918, and then was under wartime restrictions for only a few months.

Maturation in the 1920s.—The decade of the 1920s saw the automobile come into its own. In the United States the manufacture of motor vehicles, which had been too insignificant to be mentioned in the census of 1900, had now become the nation's largest industrial operation, absorbing 20% of the steel output, 80% of the rubber and 75% of the plate glass. The petroleum industry was geared almost completely to automotive requirements and the great increase in the number of motorists stimulated a program of extensive highway construction. It is fair to say that much of the business boom of the 1920s was a direct consequence of the growth of the automotive industry.

Expansion presented some problems. With automobiles multiplying in number, a market in used cars developed to proportions that handicapped the sale of new vehicles. In order to keep production moving, the manufacturers came to emphasize annual model changes, with their appeal to the customer to "keep in style"; in addition, installment selling was expanded to an unprecedented degree. One of Durant's last major achievements at General Motors was the organizing of the General Motors Acceptance corporation as a mechanism to assist dealers in financing time pay-

ments. This step in itself indicated that the industry had reached a new stage of development. In the early days the manufacturers depended heavily on their dealers for financing; now the relationship was being reversed.

The Decline of the Model T.—However, there was not a complete abandonment of the old order of things. In 1921 Henry Ford found himself in a falling market with a heavy indebtedness resulting from the building of the great River Rouge plant near Detroit, Mich., the necessity of paying accumulated arrears of dividends when he lost a stockholders' suit brought by the Dodge brothers, and his own decision to avoid further annoyance of this kind by buying out his stockholders. He resolved his difficulties by canceling orders for parts and materials, working off his inventory and shipping the finished cars to his dealers, who had to accept and pay for them or lose their franchises.

Ford, however, was rather markedly part of the old order himself. He ran his company autocratically and one by one forced out his ablest lieutenants, men like James S. Couzens, C. H. Wills and William S. Knudsen. This in itself would not have been so bad if he had not refused to recognize that times had changed and specifically that the Model T had had its day. The serviceable but distinctly ungainly "Tin Lizzie" lost its appeal in an era of improved highways and a buying public increasingly conscious of the automobile as a prestige symbol. Perhaps the used car market more than anything else killed the Model T, since for the price of a new Ford a buyer could have a perfectly usable and attractively styled second-hand car.

Yet Ford clung to the Model T until 1927. When he finally realized his error, he acted with his former decisiveness and produced the Model A of 1928 in a remarkably short time; by then, however, the Ford Motor company had forfeited its dominating position in the automotive industry and it never recovered the lost ground. It was securely enough in second place, but still second.

GM Assumes Lead.—The new leader was General Motors. After the fall of Durant, direction of the company's affairs fell into the hands of Alfred P. Sloan, Jr., under whom General Motors became the largest manufacturing enterprise in the world. His first step was to reorganize the company on the basis of his belief that it was much too big to be run by any one man and required a system that pooled talents and at the same time provided opportunity for subordinates to develop and exercise initiative. The result was a structure composed of a number of autonomous subdivisions with broad policy determined by coordinating committees. Sloan also created an effective research department, something Ford had neglected. His greatest single coup was to put William S. Knudsen in charge of the Chevrolet division, because it was Knudsen who pushed Chevrolet ahead of Ford in the low-priced car market.

Extension of Ford and GM.—Both Ford and General Motors became important factors in the European automotive industry. Ford built plants in England, Germany, France, Spain and Denmark; General Motors bought the British Vauxhall Motors in 1925 and the German Opel company in 1929. Both Ford and General Motors extended their interests to aviation, Ford through ownership for a few years in the 1920s of a company that made trimotored metal aircraft, General Motors through substantial ownership of stock in North American Aviation, founded in 1928. Ford was the only automobile manufacturer to make a success of farm machinery, especially tractors; General Motors, on the other hand, pioneered in the manufacture of electric refrigerators with the Frigidaire, a Durant legacy to the company.

The Rise of Chrysler.—These were the leviathans of the U.S. automotive industry but they were joined in the 1920s by a third concern, the Chrysler corporation, which grew large enough to make the dominant firms in the American automobile industry a "Big Three." It got its start when the Maxwell Motor Car company went into receivership during the 1920 depression and Walter P. Chrysler, who a short time before had resigned from General Motors, was asked to supervise its reorganization. He did so and eventually converted the company into the Chrysler corporation, based on a car of his design whose principal novel feature was a high-compression engine. The Chrysler car was an outstanding success and the Maxwell disappeared.

Nevertheless Chrysler would undoubtedly have remained in the ranks of the lesser producers but for his achievement in buying the Dodge Brothers Manufacturing company in 1928. This concern had been established in 1913 when John and Horace Dodge decided to become independent of Henry Ford. After the brothers died, their company was eventually sold to the banking firm of Dillon, Read and company, which in turn sold it to Chrysler. For the Chrysler corporation it meant the acquisition of a large dealer organization and manufacturing facilities that enabled Chrysler to introduce the Plymouth in 1928 as a competitor of Ford and Chevrolet.

Further Decline of the Smaller Firms.—The trend toward concentration in the automotive industry was revealed unmistakably both in the ascendancy of the "Big Three" and in the persistent decline of the smaller firms even in the prosperous period of the 1920s. The number of companies engaged in automobile manufacturing in the U.S. shrank from 108 in 1923 to 44 in 1927. At the peak of the boom the independents held only 25% of the automobile market and five companies (Hudson, Nash, Packard, Studebaker and Willys-Overland) accounted for three-fourths of that amount. The smaller firms played an important role in the industry in that they were more likely to introduce innovations than the big companies. Hudson, for example, was the first (in 1922) to offer a closed car at a price only slightly higher than that of the touring car, with the result that the latter was virtually driven off the market. E. L. Cord in 1929 produced a car with front-wheel drive that was a commercial failure mainly because it came on the market at the worst possible time. Nevertheless, the independents by and large could not maintain themselves against the advantages that large-scale techniques in production and marketing gave to the big companies.

This pattern did not apply as strongly in the manufacture of trucks, buses and other commercial vehicles. Since trucks and buses were specialized products that lacked the mass market of passenger cars, independent firms such as the Autocar company, the Mack Truck company and the White Motor company were able to maintain themselves in this field. These three were typical of most truck manufacturers in that they had all engaged in passenger car production, quite extensively in the case of White, before deciding to concentrate on commercial vehicles.

Similarities and Differences.—The British automotive industry displayed many similarities to the U.S. pattern of concentration of manufacturing in a few large concerns. Two companies, Morris and Austin, emerged as vigorous competitors for the low-priced car market and by 1929, along with Singer, they controlled 75% of the output of cars. The total number of firms engaged in automobile manufacturing in Britain declined from 88 in 1922 to 31 in 1929. The increasing importance of the automotive industry in the British economy was reflected in the growth of a considerable number of companies concentrating on the production of motor vehicle parts and components. Supplier firms had been an integral part of the industry in the United States from the beginning but they were a new development for Britain. When William Morris entered the automobile business just before World War I and sought to achieve quantity production by buying standardized parts from outside firms, he had to go to the U.S. to fill his needs.

In France the automotive field was dominated by Renault and Citroën, both emphasizing quantity production of low-priced cars. André Gustave Citroën, called "the Henry Ford of France," showed clearly the influence of American production and marketing methods. He began to make motor cars in 1919 and soon attained an output of 400 a day, until in the middle 1920s 40% of the automobiles in France were Citroëns. The most spectacular of his marketing techniques was his use of the Eiffel tower to display illuminated signs. The German automotive industry reflected the trend to consolidation in a historic merger; Daimler and Benz joined forces in 1926 as the Daimler-Benz A.G.

Along with the similarities in the development of the automotive industry in the principal producing countries, there were

some noticeable differences. The popular-priced European cars were light vehicles with engines not exceeding 10 h.p., whereas the Model T Ford began with a 20 h.p. engine. To some extent this situation was produced by tax laws, notably in Great Britain, which taxed motor vehicles according to their horsepower rating. The high cost of motor fuels in Europe was a more important consideration. Moreover, despite the efforts of men like Morris, Austin and Citroën, the ownership and use of motor vehicles in Europe did not approach the level reached in the United States, where by 1929 there was one automobile for every six people. In other words, the point had been reached at which the entire population of the United States could be transported by car simultaneously. The volume of highway travel by private automobile cut heavily into the passenger business of American railways and motor truck competition was becoming a serious threat to rail freight traffic.

The United States was counting its automotive output in millions while other countries were still counting theirs in hundreds of thousands. Consequently, although American methods were widely admired and imitated, they could not be adopted in full. It was simply not economically feasible for European manufacturers to employ the elaborately specialized and highly expensive machine tools that American automobile factories used. Even in as comparatively large-scale a producer as Morris Motors, the moving assembly line was not introduced until 1934.

THE IMPACT OF THE DEPRESSION

Government Controls and Falling Production.—The coming of the prolonged, worldwide depression of the 1930s was bound to have pronounced effects on an industry that had become as important economically as the automotive industry. There had been a few depressions in the brief lifetime of the industry but they had been short-lived, scarcely interrupting the continuously increasing output of motor vehicles. Now, however, automobile manufacturers found themselves in the unaccustomed position of facing a sustained decline in the demand for new cars. Moreover, governments reacted to the depression with political and economic remedies of varying kinds, and these of necessity included the automotive industries in their scope.

The most general consequence of the depression for the automotive industry was the extension of governmental controls to an area that had been a stronghold of *laissez-faire*. Except in the Soviet Union, which in the 1930s was not a significant producer of motor vehicles anyway, the industry had functioned as something close to a classic example of private enterprise and free competition. It is true that by the 1920s it was increasingly difficult for a newcomer to establish himself in the field and the smaller firms were engaged in a desperate struggle to survive, but these conditions were a consequence of mass production and the advantages of large-scale operation. They were not the result of either monopolistic combination or legislative direction of business policy.

This situation now changed drastically, with the degree of change varying in accordance with the response of the several industrial nations to the pressures of economic crisis. Moreover, the progressive deterioration of international relations during the 1930s drew governmental attention to the productive capacity of automotive plants for military purposes. Thus the Nazi regime in Germany, while it left the factories nominally in private ownership, regulated the activity of its automotive industry to conform to the objectives of the regime and particularly to implement Hitler's planning for war. It is a striking tribute to the universal appeal of the automobile that the Nazis themselves felt obligated to promise the German people what Henry Ford many years before had termed "a car for the multitudes"—in this case the Volkswagen. However, military exigencies, specifically the need for equipping the armored and motorized divisions that were later to swarm across Europe, kept the bulk of Germany's automotive output from reaching the civilian market.

In France, by contrast, while automobile production declined, the structure of the industry did not change appreciably. Citroen had to go into receivership and became the property of the Michelin Tire company. On the other hand, a newcomer, Simca, rose to be a major producer during the 1930s.

The U.S. automobile industry was hard hit by the depression. Production dropped from the peak of more than 5,000,000 vehicles in 1929 to a low of just over 1,000,000 in 1932, and while output climbed fairly steadily thereafter, the figure for 1929 was not surpassed in peacetime for more than 20 years. Yet while production fell off drastically, automobile registrations did not; the motor vehicle was so thoroughly integrated into the fabric of American life that even in the depth of depression people held on to their cars.

The industry's response to the depression was to cut costs (and here the larger firms had a considerable advantage in that minor economies could add up to a substantial aggregate for them) and to intensify sales efforts. The battle for sales offered a definite incentive to technical advance, since anything that could be advertised as an improvement was of value. So Studebaker introduced free-wheeling in 1930, Chrysler the overdrive in 1934, and Oldsmobile the automatic transmission in 1937.

Meanwhile, the automotive industry had to face the conditions resulting from the economic program of the New Deal. The effect of the provision of the National Industrial Recovery act of 1933 for codes of fair competition was slight. The act was opposed by the industry but all the manufacturers except Henry Ford complied with it. Ford successfully defied the code authorities and his competitors found themselves free of code restrictions when the supreme court invalidated the NRA in 1935.

Organization of the U.A.W.—Of more permanent significance was the unionization, with the full sympathy and support of the New Deal administration, of an industry that had previously been completely and even aggressively open shop. The United Automobile Workers was a product of the founding of the Committee for Industrial Organization (C.I.O.) in 1935. Their drive on the automotive industries began in earnest with the passage of the National Labor Relations act (Wagner act) in 1935 and was marked by bitter conflict. While the constitutionality of the act remained in doubt, the industry refused to yield; the union retaliated by importing from France the technique of the "sit-down" strike. However, the outcome of the election of 1936 and the sustaining of the Wagner act by the supreme court in the following year prompted General Motors to change its policy. It agreed to accept the U.A.W. as the bargaining agent for its employees, whereupon most of the rest of the industry followed suit. Ford, as usual, went his own way, and some years of violent conflict ensued before the Ford Motor company and the U.A.W. finally came to terms.

Continued Concentration.—The predominant influence of the depression on the American automobile industry was to confirm the trend toward concentration. The "Big Three" rode out the storm, not without difficulty but certainly with considerably less than their smaller competitors. General Motors even expanded into a new field, diesel engines. In 1930 it bought the Winton Engine company, founded by automobile pioneer Alexander Winton in 1912 to make diesels, and the Electro-Motive company, which had been designing gasoline-powered railroad cars since 1922 and was experimenting with diesel propulsion. The purchase brought the talents of Charles F. Kettering directly into the diesel field. Within a decade improvements on the diesel engine brought it to a degree of efficiency that resulted in diesel locomotives superseding the steam locomotive in railway transportation and in diesel power being used on trucks and buses.

The ability of a big organization to survive difficulties that would rapidly put a small one out of business was clearly illustrated by the Ford Motor company, which had to contend not only with depression but also with problems created by the personality of its aging founder. Henry Ford ruled his company as an autocrat. He had always done so but as he grew older he became more and more arbitrary and unpredictable. His defiance of the NRA and his long battle with the U.A.W. were typical of his unwillingness to accept any change that threatened his freedom to do as he pleased. The internal organization of the Ford Motor company offered evidence of a comparable unwill-

ingness to delegate authority. Not only were the responsibilities of Ford executives poorly defined, but assertion of initiative was more than likely to result in dismissal. Nevertheless Ford still had the technical skill to produce the first low-priced V-8 in 1932, a feat made possible by the daring innovation of casting the engine block and crankcase as a single unit. So Ford remained securely in second place among automobile producers despite the vigorous and well-organized competition of the Chrysler corporation.

The situation of the smaller companies was entirely different. Between 1929 and 1939 their share of the market dropped from 25% to 10%. Many famous names like Pierce Arrow, Stutz, Moon, Kissell and Franklin (the only American car of that time with an air-cooled engine) disappeared altogether. Some companies were able to remain in existence only by changing their operations: Reo (the company founded by Ransom E. Olds after his departure from the Olds Motor Works) abandoned passenger car production in favour of trucks; Hupp, maker of the Hupmobile, turned to the manufacture of automotive parts and subsequently expanded into electronics and chemicals; Marmon gave up luxury cars for special-purpose, all-wheel-drive trucks; Peerless, in the most astonishing conversion of all, became a brewery.

Of the surviving independents, Studebaker and Willys-Overland both had to go through receivership and reorganization. Hudson, Packard and Graham-Paige managed to remain solvent with considerable effort. Nash sought safety in diversification and merged in 1935 with the manufacturer of Kelvinator refrigerators as the Nash-Kelvinator corporation.

Differences in Britain.—The experience of the British automobile industry in the depression showed some distinctive features that appear to be deviations from the pattern established elsewhere. To begin with, British production of motor vehicles declined by only 15% between 1929 and 1932, compared with 75% in the United States and Germany, 33% in France and about 50% in Italy; and when business began to recover, British production by the mid-1930s was well ahead of what it had been in the previous decade. This impressive record was achieved without either the type of governmental intervention represented by the New Deal in the United States and the Popular Front in France or the stimulus of an armament program such as Germany and Italy employed. The explanation appears to be twofold: the British automotive industry grew rather more slowly than its competitors during the 1920s and therefore was less subject to the violent "boom and bust" cycle that occurred elsewhere; and, during the depression, per capita real income in Britain fell relatively less than in other industrial countries.

The British industry seemed to deviate also from the trend to concentration. Where there had been three major producers in 1929, there were six in 1938: Morris, Austin, Ford, Vauxhall, Rootes and Standard, in that order (Singer was no longer among the leading firms). On closer examination, however, it is clear that Britain was not as much of an exception as appearances suggest. Ford and Vauxhall were by no means "independents" competing with big combines. The rise of Ford in the British market was due to a reorganization of Ford's overseas operations in the late 1920s that gave Lord Perry, the head of Ford of Britain, both a new factory and a freer hand to run the business without interference from Detroit. Vauxhall, of course, had acquired the powerful support of General Motors. Rootes Motors, Ltd., and Standard Motors, Ltd., were new combinations, Rootes of Hillman, Humber and Sunbeam, Standard of Triumph and Standard. The "Big Six" accounted for 90% of British automotive production in 1938. The fact that the British had six major firms compared with three in the United States was due to the smaller size of the British market. British manufacturers built about 400,000 passenger cars in 1938 compared with 2,000,000 in the United States; the economies of large-scale operation were consequently less of an advantage in Britain.

WORLD WAR II AND AFTER

Contributions to the War Effort.—The outbreak of war in 1939 terminated the situation in which automotive producers had to contend with inadequate demand. Instead, their factories were called upon to work at full capacity to meet the requirements of mechanized warfare. The automotive industries of the belligerents not only made vehicles but participated in the manufacture of aircraft, guns, munitions and a host of other items.

Since the automotive industry was larger in the U.S. than in all the other countries combined, its war experience is the most useful to examine. As early as May 1940, William S. Knudsen, then president of General Motors, was called to Washington to assist in organizing defense production and efforts were begun to control automobile manufacture in order to conserve machine tools as well as to employ the resources of the industry to expand aircraft production. However, effective conversion to a war footing was not achieved until the United States became an active belligerent.

The total contribution of the industry to the war effort can be indicated by some sample production figures: 2,500,000 trucks; 6,000,000 guns; 500,000 aircraft engines; 5,000,000 bombs and so on through an extensive list to such items as 100 mi. of submarine nets. Among the motor vehicles manufactured special mention should be made of the Jeep, a four-wheel-drive, ubiquitous vehicle designed by Willys-Overland.

This wartime achievement was not without its problems. There was a too facile assumption that automotive manufacturing equipment and techniques could be readily transferred to the mass production of other things, especially aircraft. When delays occurred, as they were bound to do, both the automobile and aircraft industries were subjected to a good deal of criticism. The automotive industry in the end built about 10% of the aircraft made in the United States during the war. Automotive engineers and production men also analyzed techniques of aircraft manufacture and passed along their experience in quantity production. The same procedure was followed in such areas as ordnance manufacture and shipbuilding.

Postwar Surge in Demand.—The return of peace brought with it a demand reminiscent of the early days of the industry, but in this case caused by the suspension of nonmilitary production over a period of years. It was a situation that attracted several newcomers into the industry and thereby provided an impressive demonstration of the virtually insuperable handicaps such attempts faced.

The most promising of these efforts was made by the Kaiser-Frazer corporation (later Kaiser Motors corporation), formed in 1946 by Henry J. Kaiser, an industrialist with a spectacular record in war production, and Joseph W. Frazer, the president of the Graham-Paige corporation. The new organization took over Graham-Paige and was able to lease manufacturing facilities built by the government during the war. Subsequently (1953) it bought Willys-Overland. Kaiser thus entered the automotive industry under reasonably favourable circumstances, with a foothold in Graham-Paige, additional plant acquired at relatively low cost and a market absorbing any vehicle that would roll. Yet the venture prospered, building cars under the Kaiser and Frazer names, only until the established automobile companies were back on a regular peacetime basis. In 1949 Kaiser was unable to get support from the private money market and had to borrow from the federal government's Reconstruction Finance corporation. Five years later Kaiser automotive activity in the U.S. was limited to the manufacture of Jeeps and trucks by the Willys organization, although a subsidiary in Argentina continued to produce and sell the Kaiser automobile there until 1962.

One fundamental weakness was that Kaiser had nothing more to offer than a purely conventional passenger automobile differing neither in technical features nor in style from its competitors. Something more was needed by any newcomer to offset the reluctance of buyers to purchase a car that might become an "orphan." The American purchaser almost without exception had come to consider future trade-in value as an important factor in his decision to purchase and therefore tended to prefer the cars whose continuing marketability seemed most promising. This factor made it difficult for a new firm to attract dealers, so that while the technical problems of manufacturing cars were met readily

enough, given sufficient capital, the likelihood of selling enough cars to justify the investment was remote.

Organizational Changes.—Among the established automotive firms the process of concentration continued. Two mergers occurred in 1954: Hudson and Nash combined as the American Motors corporation, and Studebaker and Packard as the Studebaker-Packard corporation. Among commercial vehicle manufacturers the White Motor company became the largest single firm by absorbing Autocar and Reo. However, independent producers of specialized commercial vehicles remained in the field while for a time it appeared that not even the mergers would save the independent passenger car manufacturers. General Motors, Ford (reorganized after its founder's retirement in 1945) and Chrysler dominated the market, following each other closely in styling and price policies since they had too much invested in each year's models to risk deviations that might not sell.

Trend to Smaller U.S. Cars.—The two independents survived by withdrawing from this type of competition and offering smaller and more economical cars. American Motors led the way by discontinuing the Hudson and Nash lines and concentrating on the Rambler; Studebaker-Packard dropped the Packard and retained the Studebaker name. These "compacts" did so well that the "Big Three" were compelled to introduce small cars of their own.

The swing of consumer preference to smaller cars was reflected also in substantial buying of foreign cars. American purchases provided a stimulus to the European automobile industry and expanding automotive production was a major factor in the economic recovery of western Europe. France nationalized the Renault company in 1944 but this step did not affect the behaviour of the French automotive industry. In Germany the design of the Volkswagen was salvaged from the wreckage of the Nazi regime and within ten years the car accounted for half of Germany's automobile production.

Further Concentration in England.—The British automotive industry benefited from the rising demand for small cars after the war and in its growth continued the trend to concentration in a few large firms. The most important step in this direction was the consolidation of Austin and Morris in 1952 as the British Motor Corporation, Ltd., creating an organization that produced 40% of British automobile output and reducing the number of major firms from six to five. These five controlled 95% of the market for British cars. For some years after the war this was predominantly an export market. Britain had as large a backlog of civilian demand as any other country but motor vehicles bulked so large as assets for earning foreign exchange that most British automotive production was earmarked for export until the early 1950s.

This situation accentuated the handicaps under which the smaller firms laboured. The immediate postwar years constituted a period of shortages of materials and parts, and the big companies were not only more self-sufficient but, because of the larger volume of their orders, were at an advantage in bidding for limited supplies. Some of the British independents disappeared; some were merged with their larger competitors, as Singer was absorbed by Rootes in 1957. Those that survived either made highly specialized vehicles, such as the Jaguar (which sold so well that the manufacturer found it necessary to increase plant capacity and consequently bought the British Daimler factory in 1960), or they were in a category peculiar to Britain, that is, a group of cars manufactured by companies whose major interests lay elsewhere. The prime example was Rolls-Royce, Ltd. Only about 10% of its business was represented by the manufacture of Rolls-Royce and Bentley cars, the rest consisting principally of aircraft engines.

AUTOPSY (Post-Mortem Examination; Necropsy) is the scientific examination of a dead body for the purpose of establishing the cause of death or of correlating the clinical manifestations of diseases with the morbid changes in tissues. The examination may be done for legal purposes (*see* Coroner; Medical Jurisprudence) or for the extension of medical knowledge. Cases of real or suspected homicide and other cases specified by law are referred for examination to the coroner or medical examiner. In other cases, consent for an autopsy is required from the nearest of kin, such as the widow or widower, a parent or offspring. Their rights are violated when an autopsy is made without consent, and legal redress is possible. Religious teachings have been offered as a reason for refusal, but authoritative search in the Jewish and Christian religions fails to reveal any interdiction.

Autopsies, as a rule, are performed by pathologists—physicians specifically trained in this field. Skill and special knowledge of the tissue changes caused by injury or disease are required for this work. In addition to a gross inspection, microscopic studies, bacteriologic and chemical examinations of tissues may be required, and in coroner's cases an understanding of all phases of forensic pathology is necessary. When autopsies are made for the extension of medical knowledge, both the physician and his living patients benefit. Without an autopsy, the cause of death is largely an opinion as distinguished from a fact. Physicians of great skill frequently see unsuspected diseases revealed by autopsy. In fact, the diagnosis of diseases by physicians rests upon the accumulated experiences of autopsies during many past generations. The benefits of autopsies to the public include improved medical practice, satisfaction in knowing the facts, disclosure of a communicable disease against which the living can be protected, insurance claim benefits and others. (E. F. Hh.)

AUTUN, a cathedral city in central France, is in the old duchy of Burgundy and the modern *département* of Saône-et-Loire. Pop. (1962) 14,003. The town, which is situated in a synclinal basin of sedimentary rocks surrounded by the crystalline highlands of the Morvan, overlooks the left bank of the Arroux, a tributary of the Loire, and lies 50 mi. S.W. of Dijon. Succeeding to the Gaulish *oppidum* of Bibracte, Augustodunum (Autun) was an important Roman city, renowned for its schools of rhetoric. Fine Roman gates of the 3rd century (St. André and Arroux) and much of the Roman walls remain, as well as a Roman theatre and, across the Arroux, a great tower (Temple of Janus). The cathedral of St. Lazare, once the chapel of the dukes of Burgundy, dominates the city and is one of the finest of the Burgundian group of Romanesque churches. The central bell tower and chapels in the Gothic style were added in the 15th century by Nicolas Rolin. The sculptured group of the last judgment above the west door and Jean Ingres' painting of the martyrdom of St. Symphorien (at Autun in 179) are especially noteworthy. The Hôtel (musée) Rolin (15th century), the ancient bishop's palace and the town hall house museums; collections in the hôtel include a painting of the Nativity attributed to the Maître de Moulins (15th century), the Virgin of Autun (15th century) in polychrome stone and a 12th-century sculpture of Eve.

Autun is an important market for the livestock of the Morvan, and has leather, timber and metal industries. A small refinery extracts oil from shale worked locally in the small Épinac coal field. (Ar. E. S.)

AUTUNITE or Calco-Uranite, a secondary uranium mineral which is one of the "uranium micas" and one of the ores from which uranium is produced. Autunite is usually found with pitchblende and other uranium minerals. A lime uranite, it differs from the more commonly occurring torbernite (*q.v.*) or cuprouranite in containing calcium in place of copper. It is a hydrous uranium and calcium phosphate, $Ca(UO_2)_2(PO_4)_2+8(\text{or } 12)H_2O$. The dehydration form, meta-autunite, differs only in the number of water molecules present. Though closely resembling the tetragonal torbernite in form, autunite crystallizes in the orthorhombic system and is optically biaxial. The crystals have the shape of thin plates with very nearly square outline. An important character is the perfect micaceous cleavage parallel to the basal plane, on which plane the lustre is pearly. The colour is sulfur-yellow, and this enables the mineral to be distinguished at a glance from the emerald-green torbernite. Hardness is 2 to 2.5 and specific gravity 3.05 to 3.19. Fluorescence under ultraviolet light is brilliant yellow to yellowish-green. Radiations can be

detected by Geiger counter. *See* URANIUM; NATURAL RESOURCES: *Minerals*.

AUVERGNE, an ancient province of France, corresponding to the modern *départements* of Cantal (ancient Haute-Auvergne) and Puy-de-Dôme (Basse-Auvergne) with the *arrondissement* of Brioude in Haute-Loire. It contains many mountains volcanic in origin (Plomb du Cantal, Puy-de-Dôme, Mont-Dore), fertile valleys such as that of Limagne, vast pasture lands and numerous medicinal springs.

In Caesar's time the Arverni (*q.v.*) were a powerful confederation, their chieftain Vercingetorix being his foremost opponent in Gaul. The Romans made Arvernia part of Aquitania Prima. It was the seat of a countship under the Carolingians. After the rule of the powerful Guilhem (William) the Pious, count from 886 to 918, the viscounts of Clermont (now Clermont-Ferrand [*q.v.*]) usurped the hereditary title of counts of Auvergne.

Through the marriage of Eleanor of Aquitaine with Henry Plantagenet, the counts became vassals of the kings of England. But Guilhem VII the Young (1145–68) lost much of his domain to his uncle Guilhem VIII the Old (who was supported by Henry II), retaining only the region bounded by the Allier and the Coux—it was this district that from the end of the 13th century was to be called the Dauphiné d'Auvergne (*see* DAUPHIN). Philip II Augustus of France intervened in the family quarrel and succeeded in possessing himself of a large part of the country (1195), which he annexed to the royal domain under the name of Terre d'Auvergne. For his concurrence in this matter the bishop of Clermont, Robert I (1195–1227), was granted the lordship of the town of Clermont, which subsequently became a countship (to be distinguished from the countship of Clermont-en-Beauvaisis). Such was the origin of the four great lordships of Auvergne.

The Terre d'Auvergne was from 1241 to 1271 an appanage of Alphonse of Poitiers, who was successful in curbing the local nobility. Then it was under the crown until 1360, when John II of France made it a *duché-pairie* for his son Jean, duc de Berry (died 1416). In 1425 the ducal title was secured to Jean I, duc de Bourbon, husband of Berry's heiress Marie. Jean I's younger son Louis, comte de Montpensier, married Jeanne, heiress of the Dauphiné d'Auvergne, in 1428, and their grandson Charles, the famous constable of France, was able to unite duchy and *dauphiné* when he became duc de Bourbon through his marriage with his second cousin Suzanne. But these Bourbon domains were confiscated by King Francis I on the constable's treason and assigned to the king's mother, Louise of Savoy, for the rest of her life, after which they were annexed to the kingdom (1532).

The countship of Auvergne, however, having passed in 1422 to the house of La Tour, descended to Catherine de Médicis, who moreover got possession of Clermont in 1551. These domains were annexed to the crown in 1615, on the death of Catherine's daughter Margaret of Valois. The *généralité* of Riom was established in 1577. The *intendants* had their seat at Clermont.

AUWERS, (GEORG FRIEDRICH JULIUS) ARTHUR VON (1838–1915), German astronomer whose name is now most closely associated with a new reduction of the observations made by James Bradley at Greenwich, London, in the middle of the 18th century, was born on Sept. 12, 1838, at Göttingen in Hanover and studied there and at Kaliningrad. In 1866 he was called to Berlin as astronomer to the Academy of Sciences. Auwers' results, combined with later observations of the same stars, served for the construction of a fundamental catalogue of some hundreds of stars. This catalogue formed the basis for the accurate determination of the positions of stars down to the ninth magnitude from observations made at observatories in a number of countries under the auspices of the German Astronomical society. Auwers directed German operations to observe the transits of Venus in 1874 and 1882, and himself traveled abroad to observe them. From the observed variable proper motions of Sirius and Procyon he confirmed F. W. Bessel's hypothesis that these stars had unknown invisible companions. He died in Berlin on Jan. 24, 1915. (J. JN.)

AUXERRE, a town in central France and capital of the *département* of Yonne in Burgundy, lies on the Yonne river 172 km (107 mi.) S.E. of Paris by road. Pop. (1962) 28,949. The town is irregularly built along the river bank, with steep and narrow streets. The cathedral of St. Etienne (13th–16th century) is a magnificent Gothic building with three richly sculptured doorways and a rose window on the west front. A massive square tower rises in the northwestern corner, but that in the southwestern corner was never finished. The early Gothic choir and the beautiful apsidal chapel contain some of the best 13th-century stained glass in France. In the 11th-century crypt is a unique fresco (12th–13th century) depicting Christ on horseback surrounded by four mounted angels. Beyond the covered market is the Place de l'Hôtel de Ville, the historic centre of the town and mostly 17th century. The church of St. Eusèbe, near the commercial centre was founded in the 7th century and shows styles from the 12th to the 16th. A clock originally installed in the belfry (then the highest point of the town) in 1411 was moved in 1483 to one of the Roman gateways, which was rebuilt after a fire in 1825 and is now known as the Tour de l'Horloge. Below the church of St. Germain crypts of the 9th century contain tombs of the bishops of Auxerre. The 6th bishop, St. Germain, was buried there in 1448 and every year on July 31 there is a procession when the saint's relics are exposed in the cathedral. Of the original Benedictine abbey of St. Germain nothing remains; it was rebuilt in the 17th century. There is an art museum and a library. The chief product of Auxerre is wine (especially Chablis) from the surrounding vineyards, while ochre, pies, cardboard boxes, trailers and metal goods are produced and printing is carried on. Auxerre (Autessiodurum) became the seat of a bishop and a *civitas* in the 3rd century. Founded under the Merovingians, the abbey of St. Germain in the 9th century became a seat of learning. Joan of Arc twice passed through the town, the second time with Charles VII on their way to his coronation at Rheims. Napoleon also went through Auxerre on his return from Elba.

AVA, the ancient capital of Burma, is situated in Sagaing district on the left bank of the Irrawaddy, where the Myitnge river joins it, 6 mi. S. of Mandalay, the last royal capital. The word is a corruption of *Inwa*, "the entrance to the lake." The foundation site was chosen in preference to Pagan in A.D. 1364, because from it the supply of rice from the Kyaukse irrigated area could be controlled. This area became vital to a royal city in the dry zone as the establishment of the independent Mon kingdom in Lower Burma, consequent upon the Mongol conquest of Pagan in 1287 threatened the rice supply from the wet zone in the south. At Ava Burmese-Buddhist culture flourished until the city was destroyed by the Shans in 1527. It did not become a capital city again until 1634. In 1752 the Mons captured it, but the Burmese leader, Alaungpaya, who recovered it and reunited Burma, made Shwebo 60 mi. N. of Ava, his capital. Under the Konbaung dynasty, which he founded, Ava was again the capital from 1765 to 1783 and from 1823 to 1837. The dynasty changed its capital frequently and built two new ones, Amarapura in 1783 and Mandalay in 1857 but its headquarters was always referred to by outsiders as the "Court of Ava." European travelers from the 15th century onward nearly always used the term "Ava" for Upper Burma in their accounts of the country. Today the site is almost desolate. (D. G. E. H.)

AVALANCHE, a large mass of snow and other materials which moves rapidly down a mountain slope. An avalanche begins when a mass of material overcomes frictional resistance of the sloping surface, often after its foundation is loosened by spring rains or is rapidly melted by a *föhn* (warm, dry wind) or other causes. Noises—artillery fire, thunder or man-made blasts—can start the snow in motion when the mass is just poised. Avalanches carry a considerable amount of rock debris with the snow and are therefore a geological agent of some significance; in addition to transporting unsorted materials to the bottoms of slopes, they may, if repeated, effect an important amount of erosion, as in some mountains of the western United States. Avalanches can be very destructive; in periods of exceptionally heavy snow in the Alps whole villages have been destroyed by them, in some cases with considerable loss of human life.

For discussion of the dangers presented by avalanches to mountain climbers, skiers, and travelers in mountainous terrain, *see* MOUNTAINEERING. For the geologic process involved, *see* GEOLOGY: *Physical Geology: Erosion by Mass Movements*; LANDSLIDE.

AVALON, the island of Avalon, to which King Arthur was conveyed for the healing of his wounds after his final battle, and from which he never returned.

It is first mentioned in Geoffrey of Monmouth's *Historia regum Britanniae*; in the same author's *Vita Merlini* (*c.* 1159), it is described as "the island of fruits (or "apples"), called Fortunate," where the soil yields harvests without sowing and where the inhabitants are noted for their longevity. Morgan rules the island, assisted by her eight sisters; all are skilled in leechcraft and other learned arts. Strongly influenced by his classical reading, Geoffrey's account may nevertheless reflect traditions about a Celtic elysium. The name in the *Vita Merlini*—"Insula Pomorum"—supports attempts to connect Avalon with the Celtic word for apple (modern Welsh *afal*). Sir John Rhys preferred the interpretation "Aballach's island," Aballach being a (hypothetical) "dark Celtic divinity." The identification of Avalon with Glastonbury, Somerset (attested in interpolations in William of Malmesbury's *De antiquitate Glastoniensis ecclesiae*), may have been based on Celtic stories about a mythical "summer land" and an "isle of glass" inhabited by deceased heroes, but it is equally likely to have been an attempt by Glastonbury monks to exploit the prestige of the Arthurian legends for the benefit of their own community, just as later the popularity of the Grail legend (*q.v.*) led them to claim that Joseph of Arimathea had established himself at Glastonbury.

AVANTI, a kingdom of ancient India (roughly mod. western Malwa [*q.v.*]), whose capital, about 600 B.C., was Mahishmati (probably modern Mandhata [*q.v.*] on the Narbada), but soon after, as ever since, was the famed Ujjayini (near mod. Ujjain; *q.v.*). Through it passed the overland trade between northern and southern India, and also wares on their way to the great port of Bharukaccha (mod. Broach), thence by sea to southern India and Burma, Egypt, Arabia and Babylon. By the lifetime of the Buddha (*c.* 563–*c.* 486 B.C.), Avanti was one of the four powers of northern India, strong enough under King Pradyota the Fierce to threaten the empire of Magadha. At this time there was also an Avanti-dakshinapatha, "Avanti-of-the South" (mod. Nimar?), of which Mahishmati was quite possibly the capital. By the 3rd century B.C., however, Avanti had been absorbed into Magadha. Ujjayini, one of the seven holy cities of the Hindus, renowned for its beauty and wealth, became a centre of early Buddhism and of Jainism. After 150 B.C., in the empire's decline, the Sungas, Andhra-bhrityas and Sakas fought for Avanti; and in the 2nd century A.D., Ujjayini under Rudradaman was the prosperous capital of the western Saka satrapy. About A.D. 390 Chandra Gupta II finally expelled the Sakas and held court at Ujjayini: he may well have been the fabled Vikramaditya, hero and patron of the poet Kalidasa. The name of the Malava tribe now gradually replaced that of the Avantis as the designation of this land. (R. TH.)

AVARS, a people of undetermined origin and language, who played an important role in eastern Europe during the 6th–9th centuries A.D. They are called Abaroi or Varchonitai in Byzantine sources, Obri in Slavonic.

The Byzantine historian Priscus, writing of the years 461–465, mentions a migration in which a number of peoples, including the Avars, took part, and the scene of these movements was certainly a country remote from Byzantium. At the time of their first political contact with the Byzantines, through an embassy sent to the emperor Justinian I in 558, the Avars were living in the Caucasus region, near the Alans, where they were then relatively newcomers.

It has often been suggested that the Avars were identical with the Juan-juan, who, from the beginning of the 5th to the middle of the 6th century, controlled territories adjoining the western borders of China; and that when the Türks had ousted them from their empire in Mongolia (555), the Juan-juan migrated to the west and emerged there under the name of Avar. This theory is not only unwarranted but is untenable if the Avars appeared, as Priscus says, on the Byzantine horizon almost a century before the destruction of the Juan-juan empire. A statement by Theophylactus Simocattes, that the Avars were in fact only pseudo-Avars who assumed this name, has been shown to be only a literary cliché. Much better evidence is available to show that the Avars were in some way connected with the Hephthalites (*q.v.*).

Research into the origins of the Avars is greatly hampered by ignorance of their language. Some of their proper names and titles are undoubtedly derived from Turkic or Mongol languages, but most recorded Avar words have resisted explanation.

In 565 another Avar embassy visited Constantinople; this marked the beginning of a period of about 100 years during which relations with the Avars, in war and peace, remained in the foreground of Byzantium's foreign preoccupations. The Avars intervened in Germanic tribal wars, allied themselves with the Lombards to overthrow the rule of the Gepidae (allies of Byzantium) and, between 550 and 575, established themselves in the Hungarian plain, between the Danube and Tisza rivers. This area was to remain the centre of their empire and has yielded much relevant archaeological evidence (more than 30,000 Avar tombs have been unearthed in Hungary).

The Avar empire reached its apogee under the leadership of its khagan Bayan; it covered the vast expanses between the Adriatic and the Baltic seas, the Elbe and the Dnieper rivers and thus bordered upon and incorporated many peoples. The Avars engaged in wars not only against the Byzantines (in 626 they nearly succeeded in occupying Constantinople) but also against the Merovingians. They also played an important part in the historical development of the Slavonic peoples and particularly in the southward migration of Serbs and Croats.

The Avars in Hungary maintained links with central Eurasia, and in the second half of the 7th century the representatives of the first Avar rulers in Hungary were swept away by a new wave of invaders, also Avars, but from the eastern parts of the empire. Archaeology gives striking evidence of this great cleavage in Avar history. The revolt that led, in 680, to the creation of a Bulgarian state in the Balkans gave a further shock to the greatly weakened Avar state. This, however, survived for another century, until Charlemagne, weary of their periodic incursions into Frankish territory, led three successful campaigns (791, 795, 796) into the country of the Avars and occupied their circular fortifications (the "rings"). In 805 the remaining Avars, partly Christianized, made their submission to Charlemagne.

AVATAR (AVATARA), in Hinduism, an incarnation of God, especially of the god Vishnu. The doctrine of avatars—the belief that when evil becomes too great in the world God takes the form of a human being in order to save mankind—was first formulated in the Bhagavad Gita. There are ten avatars of Vishnu, the last of which is yet to come. *See* HINDUISM; VISHNUISM.

AVEBURY, JOHN LUBBOCK, 1ST BARON (1834–1913), English banker, politician and naturalist, was born in London, April 30, 1834, the son of Sir John William Lubbock, 3rd baronet, himself a highly distinguished man of science. John Lubbock was sent to Eton in 1845, but three years later was taken into his father's bank and at 22 became a partner. In 1865 he succeeded to the baronetcy. His love of science kept pace with his increasing participation in public affairs. He served on commissions upon coinage and other financial questions, and at the same time acted as president of the Entomological society and of the Anthropological institute.

Early in his career Lubbock initiated several banking reforms of great importance, while such works as *Prehistoric Times* (1865) and *The Origin of Civilization* (1870) were proceeding from his pen. In these studies he coined the terms Paleolithic (Old Stone

Age) and Neolithic (New Stone Age), which remain current in archaeology (although with changed connotations). In 1870, and again in 1874, he was elected a member of parliament for Maidstone. He lost the seat at the election of 1880, but was at once elected member for London university, of which he had been vice-chancellor since 1872. He promoted various measures in parliament, including the Bank Holidays act, 1871, and bills dealing with absconding debtors, shop hours regulations, public libraries and the preservation of ancient monuments. He was an indefatigable and influential member of the Unionist party. As a writer of popular scientific books, Lord Avebury (he was raised to the peerage in 1900) had few rivals in his day. He died on May 28, 1913, at Kingsgate Castle, Kent.

Among his other works were: *The Origin and Metamorphoses of Insects* (1873), *British Wild Flowers* (1875), *Ants, Bees and Wasps* (1882), *Flowers, Fruits and Leaves* (1886), *The Pleasures of Life* (1887), *The Sense, Instincts and Intelligence of Animals* (1888), *The Beauties of Nature* (1892) and *The Use of Life* (1894).

AVEBURY, a village in Wiltshire, Eng., part of which lies within one of the largest prehistoric ceremonial sites in Europe, enclosing 28½ ac. It is situated about 6 mi. W. of Marlborough, on the river Kennet and at the foot of the Marlborough downs. Pop. (1961) 631.

The prehistoric structure consists of a roughly circular bank of chalk 1,400 ft. in diameter, 20 ft. high and 75 ft. broad at its base, with an inner facing of chalk blocks quarried from a ditch within, 30 ft. deep, 40 ft. wide at ground level and with a flat floor 15 ft. across. There are three original entrances, north, south and west, and a fourth, facing east, which is probably prehistoric. Around the edge of the plateau so defined stands a circle of more than 100 stones, up to 50 tons in weight and made of sarsen, a silicified sandstone obtainable locally. Inside this are two smaller stone circles, each comprising about 30 uprights and approximately 350 ft. in diameter. At the centre of the southern circle stood a tall stone, with smaller boulders around it, together forming a D-shaped setting, the straight side at the west. The middle circle contained a central U-shaped structure of three large stones, the Cove. Three stones of what may have been a northern circle were found, apparently demolished to make way for the main ditch and bank. The Ringstone, a single sarsen, stood within the earthworks and main stone circle at the southern entrance. On the eastern side of the entrance causeway, the socket for a large timber post was found and on either side of this causeway there are additional stone holes that suggest a continuation of the Kennet Avenue (*see* below) into the interior of the great circle.

The sinuous West Kennet Avenue, 50 ft. wide, consists of sarsens 80 ft. apart, arranged in pairs of lozenge-shaped and rectangular stones. It linked Avebury with a small contemporary two-period temple of wood and stone, the Sanctuary, on Overton hill, 1 mi. S.E. Burials, two accompanied by late Neolithic beakers and one with a bowl of the same period, were found beside four of the Avenue stones and must be contemporary dedication deposits.

The circles of earth and stone at Avebury, and the wooden structure on Overton hill, were all probably built at the same time by native Neolithic communities, one of whose habitation sites was crossed by the Kennet Avenue. The latter is perhaps a little later and is attributable to the Rhineland Beaker Folk (*c.* 1800 B.C.), who also replaced the Sanctuary by a double stone circle.

Many prehistoric sites surround Avebury. Of these, the earthwork enclosure on Windmill hill and the West and East Kennet long barrows are earlier (*c.* 2500 B.C.); two isolated standing stones west of Avebury Trusloe (Adam and Eve; a burial with beaker was found at the foot of the former) are contemporary. Most of the round barrows must belong to the succeeding Bronze Age (*c.* 1600–1200 B.C.) but Silbury hill may be part of the Avebury complex. This mound, presumably covering a burial of unusual importance, is about 130 ft. high and is known to have a structure of sarsens at its centre.

The village of Avebury was taken over by the National trust in 1943. It includes a manor house, built about 1560, with additions dating from about 1600 and 1700, surrounded by eight gardens.

(N. DE L'E. W. T.)

AVELLANEDA, GERTRUDIS GÓMEZ DE: *see* GÓMEZ DE AVELLANEDA, GERTRUDIS.

AVELLANEDA, Argentine city, suburb of Buenos Aires 5 mi. S.E. of the federal district on the Río de la Plata estuary. Pop. (1960) 329,626. Formerly called Barracas al Sur, it was the 19th century slum, slaughterhouse and port area of Buenos Aires and was separated from it by the Riachuelo river. In 1904 it was renamed in honour of Nicolás Avellaneda, Argentine president from 1874 to 1880. Although a separate municipality, it has become enveloped in the general growth of the national capital. Its rapid and prosperous development in the 20th century has been the result of industrial and commercial growth. Among its establishments are tanning factories, distilleries, textile mills, meat-packing plants and extensive markets for agricultural and stock products. It is also the centre of the match industry. Several rail lines, tramways and motorbus lines cover the short distance to Buenos Aires and numerous bridges span the Riachuelo. The port facilities along the Riachuelo are connected to the port of Buenos Aires and utilize the same branch channel to reach the main Río de la Plata channel. The port, therefore, is a centre for foreign trade as well as for an active coastal and river trade. (Js R. S.)

AVELLINO, a city of southern Italy, Campania region, capital of Avellino province, is situated on the Sabato river 1,151 ft. above sea level, 54 km. (33.5 mi.) E. of Naples by road. Pop. (1961) 42,402 (commune). The town is built on a terrace and is surrounded by the Apennines, among which are Partenio or Monte Vergine (4,856 ft.), the site of a famous sanctuary founded in 1124 and Monte Terminio (5,860 ft.). The oldest part of the town lies around the cathedral; the modern part, the wide tree-lined streets and the Botanic garden, is outside the walls. The cathedral (12th century) was rebuilt in 1868 in the neoclassical style. The medieval customs house was rebuilt in 1675 by Cosimo Fanzago for Marino Caracciolo, prince of Avellino. The Palazzo Orsini (1461), the Seminario (1749) and the civic museum are also interesting. In the centre of the city are the ruins of the Lombard castle where in 1130 the antipope Anacletus II conceded the titles of king of Sicily, Apulia, Calabria and Capua to Roger (Ruggero) II of Altavilla, duke of Calabria. Agriculture and wine and flour production are the main industries of the people; felt hats and woolen cloth are made and sulfur is mined in the district.

Formerly known as Abellinum, the city belonged to the Hirpini and later became a Roman colony. The site was 3 km. (nearly 2 mi.) from the modern city. Conquered by the Lombards in the 8th century, Avellino was destroyed by Otto I and passed in turn to the princely families of Del Balzo, Filangieri and Caracciolo. In the rising of 1820 the first attempt was made to obtain a constitution from the king of Naples. The city became part of the Italian kingdom in 1860, and in World War II was occupied by the Allies in Sept. 1943. (M. T. A. N.)

AVEMPACE (IBN BAJJAH; in full, ABU-BAKR MOHAMMED IBN YAHYA IBN BAJJAH or IBN AL-SA'IGH) (d. 1138), the first outstanding Spanish representative of the Arabic Aristotelian-Neoplatonic philosophical tradition, was a native of Saragossa and died in Fez Mor. The tradition that he represents had been established in the east by al-Farabi on whose commentaries, now no longer extant, Avempace depended (*see* ARABIC PHILOSOPHY). He prepared the ground for Ibn Tufail and for Averroës, who used his exegesis of Aristotle to a large extent. There are editions of Avempace's work on botany, of his treatise on the union of the "active intellect" with the human soul and of his *Letter of Farewell* by M. Asin Palacios, with a Spanish translation, in *Al-Andalus*, vol. vii and viii (1940–43); and an edition of his *Rule of the Solitary* by D. M. Dunlop, with an English translation, in *Journal of the Royal Asiatic Society* (1945).

See V. A. Farroukh, *Ibn Bajjah (Avempace) and the Philosophy of the Moslem West* (1945). (R. R. WA.)

AVENARIUS, RICHARD (HEINRICH LUDWIG) (1843–1896), German philosopher, was born in Paris on Nov. 19, 1843. He became professor of philosophy at Zürich in 1877 and died there on Aug. 18, 1896. In his chief work, *Kritik der reinen Erfahrung* (2 vol., 1888–1890; 2nd ed. 1907–08), Avenarius developed a positivist theory of knowledge known as empiriocriticism

As strongly antimetaphysical as Ernst Mach, he rejected as false all differentiation between an "inner" and an "outer" experience and introduced instead the concept of "pure" experience: the presentation of the ego and that of its environment are equated as joint constituents of the single fact of experiencing. It was for his advocacy of this monistic theory of knowledge that Bogdanov (*i.e.*, A. A. Malinovsky), one of the most notable adherents of Avenarius, was attacked by Lenin in *Materialism and Empirio-Criticism* (1909); Lenin, following Friedrich Engels, maintained the standpoint of naïve realism, holding that objective reality, existing independently of consciousness, was the basis of all scientific knowledge. (M. O. G.)

AVENOL, JOSEPH LOUIS ANNE (1879–1952), French public official, was the second secretary-general of the League of Nations. He was born at Melle, Deux-Sèvres, on June 9, 1879. After graduation from the École des Sciences Politiques and the University of Paris, he became an official of the treasury in 1905. He was a member of the French financial delegation in London from 1916 to 1923 and of the League of Nations financial committee from 1920 to 1923. From 1923 to 1932 Avenol was deputy secretary-general of the League of Nations, and thereafter until his resignation in 1940 secretary-general in succession to Sir James Eric Drummond. Avenol died at Duillier, near Nyon, Switz., on Sept. 2, 1952. (D. R. Ge.)

AVENS, a name occasionally used for plants of the genus *Geum*, which belongs to the rose family (Rosaceae). Several of these easily cultivated perennials find limited use as ornamentals. *See* GEUM.

AVENTINUS (properly JOHANN TURMAIR) (1477–1534), German humanist and historian known as the "Bavarian Herodotus," was born at Abensberg (Lat. Aventinum) in Lower Bavaria on July 4, 1477. Having studied at Ingolstadt, Vienna, Cracow and Paris, he returned to Ingolstadt in 1507 and in 1509 was appointed tutor to Louis and Ernest, the younger brothers of William IV, duke of Bavaria. He wrote a Latin grammar and other manuals for his pupils and, in 1511, a history of the Bavarian dukes. In 1515 he traveled to Italy with Ernest and in 1516 assisted in founding, at Ingolstadt, a society devoted to the discovery of old manuscripts.

Appointed court historiographer by William IV and Louis in 1517, Aventinus was commissioned to write a history of Bavaria. For this he was authorized to inspect all monastic archives. The work, *Annales Boiorum*, was written between 1517 and 1521 and was later rewritten by its author in German with the title *Baierische Chronik* (first published 1566). The Latin version shows marked sympathy for the empire in its struggle with the papacy; certain passages were omitted from the German version and from the first Latin edition (1554) as unacceptable to Roman Catholics. Aventinus never definitely accepted Protestantism but sympathized with the reformers and their teachings and openly disapproved of monasticism. This was enough to cause his imprisonment for a short time at Abensberg in 1528. On his release he settled at Regensburg, where he continued to write, preparing a history of the German nation. He died at Regensburg on Jan. 9, 1534.

There is an edition of Aventinus' complete works by M. Lexer, five volumes (1882–86). There is also a modern edition of the *Baierische Chronik* by G. Leidinger (1926).

See W. Dittmar, *Aventin* (1862); Georg Leidinger, "Aventinus," *Neue Deutsche Biographie*, vol. i (1955), with bibliography.

AVENTURINE (AVANTURINE), a variety of quartz (*q.v.*) spangled with scales of mica or hematite. Most aventurine quartz is of yellow or brown colour, but a green variety containing scales of the chrome mica, fuchsite, is also known. The name aventurine is also applied to certain iridescent feldspars. The principal of these is the oligoclase occurring in gneiss at Tvedestrand in southern Norway.

The brilliant spangled appearance of such feldspars is a result of microscopic enclosures, the colours in reflected light being the interference colours of thin films. In most cases the reflecting lamellae are hematite. Aventurine feldspar is also known as sunstone. Aventurine iridescence is not confined to oligoclase, occurring also in orthoclase and labradorite. *See* FELDSPAR.

AVENZOAR (or ABUMERON; Arabic ABU MARWAN ABDAL-MALIK IBN ZUHR) (1113–62), Spanish Muslim physician, was born at Seville, where he pursued his profession with great distinction. He was a contemporary of Averroës, who, according to Leo Africanus, attended his lectures and learned medicine from him. He belonged, in many respects, to the Dogmatists or Rational school, rather than to the Empirics.

Avenzoar was one of a few "who had the courage to tilt against Galen," and in his writings he protested emphatically against quackery and the superstitious remedies of the astrologers. He described the itch mite (*Sarcoptes scabiei*) and certain diseases. His *Teisir* ("Rectification of Health") was translated into Hebrew (1280) and then into Latin by Paravicius (1490). (F. L. A.)

AVERAGE, a term used in maritime law to mean loss or damage, less than total, to maritime property (a ship or her cargo) caused by the perils of the sea. (For the mathematical meaning *see* MEAN; STATISTICS.) An average may be particular or general. A particular average is one that is borne by the owner of the lost or damaged property (unless he was insured against the risk). A general average is one that is borne in common by the owners of all the property engaged in the venture. The remainder of this article will be devoted to the theory and practice of general average. (*See* the article on MARINE INSURANCE for the treatment of particular average under marine insurance policies.)

The basic idea of general average is that when some property is voluntarily sacrificed to preserve the remainder of the property from destruction (as by throwing cargo overboard or cutting away masts to preserve the ship in a storm), the owners of the property saved must contribute to the loss suffered by the owners of the property sacrificed in such an amount that all will have contributed rateably in the proportion which the value of their property bore to the aggregate value of all the property embarked in the enterprise. The Digest of Justinian shows that such a custom of contribution was firmly established in Roman law: *Omnium contributione sarciatur quod pro omnibus datum est* ("That which is given for all is recompensed by the contribution of all"). The doctrine was attributed by the Romans to the Rhodians and is referred to in the Digest (14, 2) under the heading: *De lege Rhodia de jactu.* As a commercial society re-established itself in western Europe after the long interregnum which followed the breakup of the Roman empire, the idea of contribution among the owners of maritime property for losses incurred for the common benefit reappeared, in rich variety and with much local diversity, in all the medieval collections of customs which are often referred to as sea codes. What is now called the law of general average thus has a lineage of impressive antiquity, and the doctrine has been admitted by all seafaring nations as part of their maritime laws.

In many areas of maritime law efforts to achieve unification of diverse national laws led to the drafting of international conventions that were later ratified by most or all of the principal seafaring nations: an example is the Brussels convention of 1922 on the carriage of goods by sea (*see* MARITIME LAW). Repeated attempts to draft such a convention in the field of general average met with failure. However, a measure of agreement on a number of vexing questions was reached at meetings held at York, Eng. (1864), and Antwerp, Belg. (1877). From these meetings proceeded the so-called York-Antwerp rules (often referred to as Y.A.R.), which have been periodically revised and expanded, most recently in 1950. In their present form they consist of a series of "numbered" rules (which cover matters of detail), a series of "lettered" rules (which state general principles) and a "rule of interpretation" which provides in substance that in case of conflict the numbered rules prevail over the lettered rules. A few countries, *e.g.*, the U.S.S.R., Switzerland and Finland, have adopted the York-Antwerp rules by legislation, but in most countries the rules depend for their effect on their inclusion in contracts of affreightment (*q.v.*). There has been general acceptance throughout the world of the proposition that the particular rules on general average imbedded in national law can be displaced by voluntary agreement; thus the inclusion of the York-Antwerp rules in a charter-party or bill of lading will be effective no matter where a general average settlement takes place. Shipping interests in the United States had never

completely accepted the pre-1950 versions of the rules; with their adherence to the 1950 rules a substantial degree of world-wide uniformity was at length achieved.

Since about 1910 the courts have had little to do with general average: litigation on the subject has almost disappeared. For this phenomenon the rules are no doubt partly responsible. A satisfactory explanation of the disappearance of the subject of general average from the law reports requires, however, some consideration of the status of the general average adjuster. The statement of a general average can be, and usually is, an exceedingly complex affair: such a statement can easily make up a volume of several thousand pages. To put such a statement together requires a vast amount of technical knowledge and *expertise*. Preparation of the statement is entrusted to a general average adjuster, and since the mid-19th century the body of men engaged in this recondite profession has enjoyed an enviable reputation for skill and impartiality. In Europe and the Scandinavian countries the general average adjuster is a state official. In England and the United States he has no official status and may be associated with the offices of an insurance broker or underwriter. Irrespective of his status, appeals from his decisions are rarely taken. In this connection it is appropriate to point out that the real parties in interest in a general average settlement are not the owners of the ship and the cargo but their insurance carriers, as insurance against general average contributions is all but universal and the insurers will typically have indemnified their principals long before the conclusion of the general average settlement. Acquiescence in the adjuster's decisions is undoubtedly encouraged by the fact that he is a professional working for professionals. In several European countries, *e.g.*, Sweden and Finland, the general average adjustment is given some legal effect by statute: if not promptly appealed from, it becomes binding on all parties. In England and the United States the adjuster's statement appears to be taken merely as a proposal which is in no way binding unless assented to: the adjuster's statement, it was said in a U.S. case, is nothing more "than a provisional estimate and calculation which his principal, the owner, was free to adopt or to put aside" (*U.S.* v. *Atlantic Mutual Insurance Co.*, 298 U.S. 483 [1936]). Despite such judicial statements, the rare appeal from the work of the adjuster is almost certain to be unsuccessful.

The basic definition of a general average act is contained in rule A (Y.A.R., 1950): "There is a general average act when, and only when, any extraordinary sacrifice or expenditure is intentionally and reasonably made or incurred for the common safety for the purpose of preserving from peril the property involved in a common maritime adventure." In substance this definition reproduces the principles which had been developed by the courts as a matter of general maritime law. Where the rule touches on matters which have been left unresolved by the case law it seems to retreat into a baffling and no doubt deliberate ambiguity. We may mention two examples of issues which the draftsmen chose to leave undecided. (1) Is it necessary that the "peril," in view of which the act is taken, be objective and real or is it sufficient that the master reasonably believes that the peril exists although he is mistaken? (For example, the master, having reason to believe that fire has broken out in the hold, orders water to be pumped in. It later appears that there was no fire. If the cargo is damaged by water, is there a general average act?) (2) Is it necessary that the sacrifice (or expenditure) be successful in that the property (or some of it) eventually arrives safely at a port? Where the sacrifice is immediately unsuccessful and the entire venture is lost, it has never been supposed that there was any basis for a general average contribution: everyone has lost all he had and matters may be allowed to rest there. The infinite variety of circumstances has, however, brought up for consideration cases in which a general average act (typically an expenditure made by the shipowner) has rescued the ship and cargo from peril, after which the ship and cargo have been lost from a cause unrelated to the original peril. In a leading case an English court concluded that there could be no contribution in general average unless some property arrived safe in port (*Chellew* v. *Royal Commission* [1921], 2 K.B. 627); the leading English treatise has continued in successive editions to express disapproval and to support the opposite conclusion (R. Lowndes and G. R. Rudolf, *General Average*, 8th ed., pp. 47, 200 *et seq.*). The York-Antwerp rules leave the issue unresolved.

The prototypical general average act was the jettison (the throwing overboard) of cargo to lighten the ship. Gradually the concept was broadened to include any type of sacrifice of ship or cargo. Naturally the ship, under the contract of affreightment, owes the cargo owner the duty of acting so as to preserve the cargo: unless the circumstances are "extraordinary," the ship has no right to ask for a contribution from cargo. In modern times the greatest development in general average law has been the putting of extraordinary "expenditures" made by the shipowner on the same level as physical sacrifices of property. The expenditure question has been considered one of great difficulty and the practice of the adjusters has varied during the last 50–75 years.

The sacrifice or expenditure must, in the phraseology of rule A, be "intentionally" (as well as "reasonably") made. In the case law "intentionally" often appears as "voluntarily" and has led to such decisions as that the scuttling of a ship at its wharf by order of a municipal fire department was not a general average act because the act was not taken by the voluntary choice of the master (*Ralli* v. *Troop*, 157 U.S. 386 [1895]). The concept of a choice freely made between alternatives has also come up in the case of a master's decision to run his ship aground at a favourable point, in the hope of saving some of the cargo, when the only alternative is to run on reefs and rocks at another point and lose everything. In the United States the ship under such circumstances was allowed to claim contribution from the cargo that was saved (see *Barnard* v. *Adams*, 51 U.S. [10 How.] 270 [1850]), but in other countries a general average contribution was denied on the ground that the destruction of the ship was in any event inevitable. Rule v (Y.A.R., 1950) provides that voluntary stranding is not a general average act (except for the expenses of refloating the ship) if in any case the ship "would inevitably drive on shore or on rocks." Another manifestation of the idea that an "inevitable" loss cannot be made good in general average is the treatment of loss or damage caused in the course of putting out a fire (as by forcing water into the hold); in general such damage is made good, but cargo which was actually on fire or so situated that it would certainly have caught fire does not share, on the ground that it would in any case "inevitably" have been destroyed (rule iii, Y.A.R., 1950).

In a general average settlement the property which has been saved (which may be the ship, its freight and cargo) contributes to the loss suffered by the property which has been sacrificed (which may also be the ship, its freight and cargo) as well as to the extraordinary expenditures made by the ship. There is thus a set of claims for reimbursement and a set of values (referred to as "contributory values") on which contribution will be levied, to the end that all will bear the same proportion of loss. The valuation, on both sides of the equation, is obviously no simple matter. The general rule is that the valuation of the contributory values is to be made "upon the actual net values of the property at the termination of the adventure" (rule xvii, Y.A.R., 1950). With respect to claims for reimbursement, the rules go into elaborate detail on ship repairs (rules xiii, xiv) and provide that losses to cargo shall be made good on the basis of market values at the port of discharge (rule xvi).

It should be emphasized that the aim of a general average adjustment is not to indemnify any party but to see that all parties suffer equally, in proportion to the value that each party has at risk. The mechanics of apportionment have been stated as follows: "The value of each of the contributing interests is multiplied by a fraction which has as its numerator the sum of the general average expenses and has as its denominator the sum of the contributing values" (*Pacific Freighters Co.* v. *St. Paul Fire & Marine Ins. Corp.*, 109 F.2d 310 [1940]). A recent treatise suggests the following "highly simplified" example to illustrate the working of the principle (G. Gilmore and C. L. Black, Jr., *The Law of Admiralty*, p. 222 [1957]): Assume that a vessel under charter is worth $1,000,000, her cargo (all belonging to one owner) $1,000,000, and

the freight, to be earned on arrival, $100,000. In general average acts, the ship is damaged in the amount of $5,000; cargo worth $100,000 is destroyed, and, consequently, freight in the amount of $10,000 is lost. The sum of the contributing values (ship, freight and cargo) is $2,100,000; the sum of the general average expenses is $115,000; thus, under the formula in the *Pacific Freighters* case, the fraction by which each of the contributing values is to be multiplied to determine the share of the loss which it ought to bear is $\frac{115,000}{2,110,000}$ or $\frac{115}{2,110}$. This operation gives as the share of cargo (valued at $1,000,000) $54,761.90; as the share of the ship (also valued at $1,000,000) $54,761.90; as the share of freight (valued at $100,000) $5,476.19. Since both cargo and freight have lost more than their fair share, they must be reimbursed in an amount which will bring their loss down to that figure. The ship, which suffered a loss of only $5,000, must contribute $49,761.90 in order to bear its fair share. That contribution will be divided, $4,523.80 going to the freight interest and $45,238.10 to the cargo interest. After that distribution each of the interests will have suffered a loss of $\frac{115}{2,110}$ of its value and the general average adjustment is at an end.

The institution of general average has not escaped attack. Critics have long felt that this primitive form of self-insurance has outlived its usefulness in an age in which all the values are insured. All that is involved in a general average adjustment is a redistribution of certain losses between hull and cargo insurers; that is to say, since the insurance carriers write both types of insurance, between their hull and cargo departments. A general average adjustment is usually not only protracted but expensive. A study by Selmer of general average adjustments made in Norway and Sweden in the period after World War II indicated that the net result of the adjustments was a movement of capital from cargo interests to shipowning interests (K. S. Selmer, *The Survival of General Average* [1958]). If general average were abolished, the results would be a saving of the costs of making the adjustments and (if Selmer's conclusions are generally valid) a slight decrease in cargo insurance rates counterbalanced by a slight increase in hull insurance rates. The defenders of general average have been inclined to agree that in an age of universal insurance the institution serves no useful economic function but insist that it has a psychological justification: the master, who must come rapidly to a decision in situations of stress and danger, can exercise a fairer judgment if he knows that both the ship and the cargo must contribute to the loss; if the rule of contribution were abolished, there would be a temptation for him to sacrifice the cargo in order to save his owner's property, the ship. Selmer finds the psychological arguments no more convincing than the economic arguments and favours "a complete abolition of the general average distribution" (p. 294). Abolition of so venerable an institution will, however, be a long time coming, if it ever comes. The insurance carriers, who are the only parties in interest, appear to be content to pay a modest tribute to the general average adjusters, and the adjusters themselves are naturally in favour of a continuance of their exacting profession.

AVERESCU, ALEXANDRU (1859–1938), Rumanian army officer and statesman whose political career owed much to the popularity that he won as a military commander, was born of a peasant family at Izmail in Bessarabia, on April 22, 1859. A volunteer in the war of independence against Turkey (1877–78), he remained in the army and was sent to Italy to study at the military academy in Turin. Appointed Rumanian minister of war during the peasant revolt of 1907, he quelled it with strong measures. In 1913, as chief of the general staff, he conducted operations against Bulgaria in the Second Balkan War. In World War I he restored the prestige of the Rumanian army by his successful resistance to the Germans at Mărășești, on the Siret line (July 1917).

In March 1918, called by King Ferdinand I to form a cabinet, Averescu conducted the preliminary peace negotiations with the Central Powers. He resigned, however, before the humiliating peace treaty of Bucharest was signed (May 7, 1918). He then formed a People's league, which in 1920 became the People's party, and was prime minister again from March 1920 to Dec. 1921. He became prime minister for the third time in March 1926. In home affairs he had no distinctive program; in foreign policy he retained pro-Italian sentiments and, after a treaty of alliance with France (June 10, 1926), concluded a treaty of friendship with Italy (Sept. 16, 1926). After his resignation in June 1927 he no longer played a leading role in Rumanian politics. He was made a marshal of Rumania in 1930 and appointed a member of King Carol II's permanent crown council in March 1938. He died in Bucharest on Oct. 3, 1938. (B. BR.)

AVERNO (LAGO D'AVERNO), a lake in Campania, Italy, 10 mi. W. of Naples and about 1½ mi. N. of the village of Baia (Baiae; *q.v.*), is an old volcanic crater nearly 2 mi. in circumference. Its depth is 118 ft. and its height above sea level 7 ft.; it has no natural outlet. Its Greek name, Aornos, was explained to mean that no bird could fly across it and live, because of its poisonous vapours; its Roman name was Lacus Avernus. In ancient times it was surrounded by dense forests and it was represented as the entrance by which Aeneas descended to the infernal regions. Hannibal made a pilgrimage to it in 214 B.C. Agrippa in 37 B.C. cut down the forest and converted the lake into a naval harbour, the Portus Iulius, by joining it to the sea by a canal via Lacus Lucrinus (the Lucrine lake) and to Cumae by a tunnel over one-half mile in length. The tunnel, now called Grotto della Pace, was bored through the hill on the northwest side of Lake Averno and was usable until damaged in 1943 during World War II. The canal, however, soon became blocked because of a gradual rise of the shore. Nero's works for his proposed canal from Baiae to the Tiber (A.D. 64) seem to have begun near Lake Averno; indeed, according to one theory, the Grotto della Pace would be a portion of this canal. On the east side of the lake are remains of baths, including a great octagonal brickwork hall known as the Temple of Apollo (1st century). The so-called Grotto of the Cumaean Sibyl, on the south side, is a rock-cut passage, possibly part of works connected with the naval harbour.

AVERROËS (ABU-AL-WALID MOHAMMED IBN AHMAD IBN MOHAMMED IBN RUSHD) (1126–1198), the most outstanding representative of Arabic philosophy in Spain, known also as a writer on astronomy, on medicine and on Muslim canon law, was born in Córdoba. His grandfather, who died in the year of his birth, had been a well-known legal scholar. Little is known of the early life of Averroës. From 1169 (when Ibn Tufail presented him at court) he enjoyed the favour of the Almohade princes. He was made judge in Seville in 1169 and in Córdoba in 1171, and became chief judge in Córdoba at some later date (administering the Malikite rite which was observed in those parts of the Moslem world). In 1182 he was appointed chief physician to Abu Yaqub Yusuf (1163–84). Under Abu Yusuf Yaqub al-Mansur (1184–99), Averroës was banished from 1195 to 1198 to the small town of Lucena because of his philosophical attitude, but was restored to favour shortly before his death, which took place on Dec. 10, 1198, at Marrakesh, Morocco. He was buried in Córdoba.

Works.—For an account of Averroës' most significant doctrines *see* ARABIC PHILOSOPHY. Of his books, his main independent philosophical work is the *Tahafut al-Tahafut* ("Incoherence of the Incoherence"), a subtle and vigorous defense of Neoplatonic and Aristotelian philosophy against al-Ghazzali's determined and able attack in the *Tahafut al-Falasifa* ("Incoherence of the Philosophers"). This work of Averroës was translated into Latin in 1328 and into Hebrew about the same time; from the Hebrew a partial translation into Turkish was made in the 15th century, as well as a second Latin version in the 16th; there is an English translation from the Arabic by S. van den Bergh (2 vol., 1955). Some minor works deal with the agreement of religion and philosophy (text with Fr. trans. by L. Gauthier, 3rd ed., 1948), proclaiming, as did al-Farabi, the primacy of reason; others summarize the doctrines of the theologians without taking the theologians' side. The greater part of Averroës' philosophical output consists, however, of commentaries on Aristotle's lecture courses; but, since

Aristotle's *Politics* was not available to the Arabs, his textbook of politics was Plato's *Republic*, as it had been for al-Farabi. There are three types of commentary: (1) the great commentaries, like those of Alexander of Aphrodisias, for instance, or of Simplicius; (2) the middle commentaries, like those of Themistius; and (3) short compendiums. Many of these commentaries were translated into Latin in the first half of the 13th century (first printed in 1472–74); and in the 16th century this Latin corpus was augmented by a number of previously unknown commentaries derived from 13th- or 14th-century Hebrew versions, among them the *Epitome of the Metaphysics of Aristotle* (German trans. by S. van den Bergh, 1924) and the *Commentary on Plato's Republic* (Hebrew text with Eng trans. by E. I. J. Rosenthal, 1956). For the Latin text the Giunta editions (1550–52, 1562 and 1573–75) are the most highly esteemed. The influence of these commentaries within the Islamic world was negligible, but the use to which they were put by the so-called Latin Averroists in the Christian world is an important part of the history of scholasticism. They also strongly influenced Jewish thinkers of the middle ages (*see* Jewish Philosophy: *The Medieval Period: The Averroists*).

Two of Averroës' medical works became well-known in Latin **and have often been printed. One is a complete handbook of** medicine, *Al-Kulliyyat*, whose name, by a curious misunderstanding, became *Colliget* in Latin (trans. 1255). The other is a commentary on Avicenna's *Poem on Medicine* (trans. 1280).

Like other Arabic scholars, Averroes in his astronomy shows some independence and does not follow Ptolemy in everything. **He also wrote a complete handbook of Malikite law, in which he always compares the views of other schools.**

Gauthier, *Ibn Rochd (Averroès)* (1948). (R. R. Wr.)

AVERROISM, LATIN, a term used to characterize the thought of a number of western Christian philosophers who, in the later middle ages and during the period of the Renaissance, drew their inspiration to a greater or lesser degree from the interpretation of Aristotle put forward by the Muslim philosopher Averroës (*q.v.*; and *see* Arabic Philosophy). Different senses may be given to the term according to the degree of influence by Averroës that it is understood to imply, and the answer to the question when Averroism is first to be discerned in western scholastic philosophy depends on the sense intended. (*See* Scholasticism.)

Averroism in the 13th Century.—Ernest Renan, in his *Averroès et l'averroïsme* (1852), claimed to recognize traces of Averroist thought in scholastic philosophy from the beginning of the 13th century. Though he could not say how it had reached them by that time, he believed that it was then being disseminated by some masters of the University of Paris and by the Franciscans, and that signs of a contemporary reaction against it can be discerned in the writings of William of Auvergne, Albertus Magnus, Thomas Aquinas, Giles of Rome and Raimon Lull. Renan's view, however, is open to criticism on various counts: William of Auvergne, for instance, can be shown to have been combating not the doctrines of Averroes but those of Avicenna (*q.v.*); and it was likewise from Avicenna that some of the early Franciscans acquired the concept of a unique active intellect which, in accordance with the Augustinian doctrine of divine illumination, they identified with God—a doctrine neither Averroist nor heterodox. P. Mandonnet, on the other hand, maintained that Averroism did not develop until after 1250, but he regarded Siger (*q.v.*) of Brabant, whose works he edited, as the pioneer and leader of this school of thought in the 13th century. Mandonnet, however, had been misled by Renan's arguments and had never thoroughly investigated the sources of Siger's philosophy, with the result that he could not rightly judge the exact degree of Averroist influence on Siger.

A large number of the works of Averroës had in fact been translated into Latin—largely by Michael Scot (*q.v.*)—between 1217 and 1230, and it is clear that his importance as a commentator on Aristotle was accepted at Paris, at Oxford and at other studia from about 1230 onward. Consequently, if the appellation Averroist had to be given to any scholar who regularly consulted Averroës' commentaries and frequently deferred to his views in the interpretation of Aristotle, then Albertus Magnus, Adam of Buckfield (fl. c. 1250) and, in particular, Thomas Aquinas would have to be called Averroists, and the presence of Averroism in western Christendom could be dated from the middle of the 13th century. That, however, would give to the term Averroism a sense so broad as to be of little use to the historian of philosophy.

Another sense in which the term might be applicable to 13th-century scholastics was proposed by the Spanish historian M. Asin y Palacios, who used the expression "theological Averroism" to denote a certain method of reconciling reason and faith which he thought to be derived from Averroës and to be exemplified in the work of Aquinas. The extreme rationalism of Averroës, however, made it in fact impossible for any Christian theologian to be guided by him along this path.

The earliest recorded use of the word "averroistae" admittedly occurs in Aquinas' treatise *De unitate intellectus* (1270), where it is applied specifically to those who adopted from Averroës the doctrine of monopsychism; *i.e.*, the doctrine that there is only one single intellect or "intellective soul" for the whole of humanity. Heterodox opinions of this sort were already being advanced by Christian philosophers in the 1260s, and monopsychism was quite important for some time, but even so the fact that a philosopher maintained monopsychism is not enough to justify describing his whole system as Averroist. Furthermore, Siger of Brabant, the principal opponent of Aquinas, believed that the true interpretation of Aristotle's *De anima* was a monopsychist one and so adopted monopsychism out of loyalty to Aristotle, not out of affection for Averroës.

If, on the contrary, the appellation Averroist is reserved, as it should be, to describe only those philosophers who adopted in its entirety the whole system of Averroës, then no genuine Latin Averroists can be found in the 13th century. The doctrines condemned by Étienne Tempier, bishop of Paris, in 1270 and 1277 were not specifically Averroist, but comprised a wide variety of pagan errors, many of which were immediately derived from the works of Aristotle.

Averroism Properly So Called (14th–17th Centuries).—Genuine and complete Averroism can be found in the 14th century, in the works and teachings of John of Jandun (d. 1328) at Paris and of Taddeo da Parma (fl. *c.* 1320) and Angelo d'Arezzo (fl. *c.* 1325) in Italy. These schoolmen unreservedly adopted Averroës' interpretation of Aristotle—John of Jandun actually calling himself the "ape" of Aristotle and Averroës. Their thought was thus confined to elaborating a closed system, derived exclusively from the tradition of Averroës and completely impervious to external influence.

The basic tenet of the Latin Averroists and that which was most vehemently attacked by orthodox Christian thinkers was their assertion of the superiority of reason and philosophy over faith and knowledge founded on faith. In this they displayed an attitude of mind quite unlike that of the more or less heterodox Aristotelians of the 13th century such as Siger of Brabant and Boetius of Dacia. Siger, for example, had thought that certain logically necessary philosophic conclusions were inconsistent with Christian dogma; but he was sincere in his assertion that only the latter could be called "true," and he spared no effort to explain the apparent disparities as the result of "supernatural" or "miraculous" interventions on God's part, whereby the normal conclusions of science were contradicted in actual historical fact. At first sight the 14th-century Averroists may appear to use much the same language as Siger, but their position was utterly different. A careful study of their work and behaviour exposes the insincerity of their professions of faith, which they made from motives of prudence in order to appease the guardians of orthodoxy. They were in fact rationalists as Averroës had been a rationalist, with no Christian

belief behind their learning.

Averroës and the Latin Averroists have sometimes been credited with the theory of "double truth," which maintains the existence of two contradictory truths, one taught by reason, the other commanded by faith. In fact no medieval writer or teacher professed such a view, and those who found religion and reason irreconcilable fell apart into two groups, the Averroists giving their allegiance to reason, the others, such as Siger and Boetius, giving theirs to faith. It was only insofar as one side or the other refused to opt for either allegiance that their enemies could charge them, as in the prologue of the 1277 condemnation, with speaking as if there were two contrary truths (*quasi sint duae contrariae veritates*).

Apart from its assertion of the supremacy of reason over faith, the most characteristic tenets of Latin Averroism were: (1) the eternal and necessary creation, both for the world of spirits and for the world of matter; (2) the unicity of the human intellect—with all the psychological, religious and moral consequences of such monopsychism, which negated belief in personality, in individual immortality and in the transcendent destiny of man; and (3) psychological determinism—which is incompatible with moral responsibility.

Averroism was not taught at Paris after John of Jandun's time but it retained a stronghold in northern Italy for more than three centuries after Taddeo da Parma and Angelo d'Arezzo had propounded it. At Padua it was taught by Paul of Venice (1368–1428 or 1369–1429), Cajetanus de Thienis (1387–1465), Agostino Nifo (*q.v.*), Alessandro Achillini (*q.v.*) and Marcantonio Zimara (1460–1523). Achillini and Zimara, however, professed a mitigated Averroism which they strove to reconcile with the doctrines of the church.

The Averroists of Padua in the 16th century became involved in controversy with the Alexandrists (*q.v.*) led by Pietro Pomponazzi. These Alexandrists followed Alexander of Aphrodisias in adopting a materialistic interpretation of Aristotle and denied the spiritual nature and immortality of the human soul, whereas the Averroists postulated the existence, temporarily individualized in each man, of an eternal and universal intellect. Thus, though they disagreed about the nature of the soul, Averroists and Alexandrists were at one in denying immortality to the soul of the individual, and for this reason both their doctrines on it were condemned at the fifth Lateran council (1513). Averroism yet continued to be taught at Padua until the 17th century. Cesare Cremonini (1550–1631) was its last adherent.

AVERSA, a town of southern Italy, region of Campania, province of Caserta, is situated in the Campanian plain 17 km. (10½ mi.) N.N.W. of Naples by road. Pop. (1961) 39,862 (commune). The cathedral (11th century, rebuilt 18th century) has a fine bell tower. The other chief buildings include the 13th-century convent of the Annunciation, the Angevin castle and a psychiatric hospital founded in 1813. The musician Domenico Cimarosa was born in Aversa in 1749. Agriculture and viticulture are the main industries and Asprino wine, mozzarella (a sweet Neapolitan cheese) and dairy produce are marketed. Aversa was the centre of a Byzantine duchy until 1030 when Sergio IV, duke of Naples, gave it to the Norman, Rainolfo Drengot, making him count of Aversa. Thus Aversa became the first Norman county in Italy and a centre of culture, known for its grammar schools. It became a diocese of the Holy See. In 1860 Aversa became part of the kingdom of Italy and in World War II it was captured by the Allies in Oct. 1943. (M. T. A. N.)

AVERY, SAMUEL PUTNAM (1822–1904), U.S. artist, art dealer, connoisseur and philanthropist, who is best remembered for his philanthropic endeavours in the arts and education, was born in New York city on March 17, 1822. Beginning as an engraver on copper, he later became a skilled wood engraver and illustrated numerous books. In 1865 he established himself as an art dealer, and two years later he was U.S. commissioner at the International exposition at Paris. In memory of his son, Henry Ogden Avery, a successful architect who died in 1880, he established the Avery architectural library at Columbia university. In 1893, in memory of a daughter, he established a library in the Teachers college, Columbia university. He was one of the founders of the Metropolitan museum. To the New York public library he presented a collection of prints. He died in New York city on Aug. 11, 1904.

Avery hall, commemorating both father and son, was built at Columbia university, housing a valuable collection of works on architecture and decorative art.

AVESTAN LANGUAGE: *see* IRANIAN LANGUAGES.

AVEYRON, a *département* of southern France, comprises the southwestern portion of the Massif Central (*q.v.*). It is bounded on the north by Cantal, on the east by Lozère, on the southeast by Gard and Hérault and on the west by Tarn, Tarn-et-Garonne and Lot. Area 3,386 sq.mi. Pop. (1962) 290,442.

Aveyron consists of contrasted plateaus of crystalline and limestone rocks, extending westward from the Cévennes (*q.v.*), across the Causses (*q.v.*), to the margins of the lowlands of Aquitaine. The volcanic highlands of Aubrac form its northeastern border. The plateaus, with large areas between 2,500 and 4,000 ft. in the Causses, are deeply dissected by the Lot, Aveyron and Tarn rivers and their tributaries, which often flow in gorges 1,500 ft. or more below the flanking plateaus. The limestone Causses plateaus are in the form of the letter Z. Their northern limb, the Causse Comtal between the Lot and Aveyron rivers, is connected with the Causse Larzac in the south by the Causses de Sauveterre, Méjean and Noir of the Tarn basin. These separate the high granite plateau of Lozère to the east from lower crystalline plateaus of the west. Along the margins are some small lowland depressions such as those around St. Affrique and Décazeville etched in softer rocks. These basins and the low-lying valleys are warm and sheltered, but the plateaus have a much wetter and more severe climate. Orchards, vineyards and irrigated meadows are characteristic of the sheltered valleys, but the plateaus are mainly pastoral. The lower plateaus of the west, with more cultivation, were traditionally concerned with rye and chestnut, and were variously known therefore as *Ségalas* and *Chataigneraies*. Their farm lands, a patchwork of small enclosed fields, are mainly devoted to pasture and other fodder crops, and to potatoes. Cattle raising is the mainstay. In the Causses cultivation is much more restricted by lack of soil and water, but wheat is here the main grain crop. Sheep rearing, however, is the most widespread activity and became increasingly important after the middle of the 19th century with the emphasis changing from production of wool to that of sheep's milk for the manufacture of Roquefort cheese, which is matured in limestone caves at Roquefort near the margin of the Causses. At the same time Millau, formerly concerned with woolen manufacture, has become an important glovemaking centre. The tourist industry, especially attracted by the Tarn gorges, has become increasingly important. In the vicinity of Aubin and Décazeville is a small coal field which provides railways and gasworks over a wide area of southwest France and has local iron, zinc, glass and chemical industries.

Aveyron is especially rich in dolmens and other prehistoric monuments, and was evidently well settled in Roman times. That it now contains some of the most desolate tracts of France is especially attributable to deforestation and the ravages of grazing animals. Since the beginning of the 20th century depopulation has continued more rapidly than in most rural areas of France.

Rodez (*q.v.*), the capital, on the Aveyron; Millau, chief town for the Causses, at the outlet of the Tarn gorges; and Villefranche-de-Rouergue gave their names to the three *arrondissements* into which the *département* is divided. The *département* forms the bishopric of Rodez, under the archbishop of Albi. It lies in the educational district of Toulouse, and its court of appeal is Mont-

pellier. It corresponds closely to the ancient county of Rouergue, which was united to that of Toulouse in the 11th century, and its history is also linked with the historic province of Guienne (*q.v.*) of which it formed part. After the devastation of the Albigensian wars new colonists were settled in the area, and several regularly planned settlements (bastides), notable among them Villefranche and Sauveterre, date from this time. The monastery of Conques in the north, with a Romanesque church, is one of the most famous in France. Espalion, Najac and Sylvanès also have noteworthy castles and churches. (AR. E. S.)

AVIATION (ARTICLES ON): *see* AERONAUTICS (ARTICLES ON).

AVIATION, CIVIL. In the broadest terms, civil aviation includes all flying other than military aviation (for the latter, *see* AIR POWER). In the most common definition, civil aviation refers to the air transportation service provided to the public by airlines or private operators, but it also includes private flying for business or pleasure as well as such diverse activities as agricultural crop dusting, geological prospecting, mapping, and automotive traffic regulation. These activities are described below in the section *General Aviation.*

Most air travelers, however, associate commercial flying with civil airline operations. There are two types of airlines: scheduled carriers, which provide services between a given number of points according to an established, published schedule; and nonscheduled airlines, which offer transportation under charter contracts or in accordance with traffic demands. Scheduled airlines in turn can be classified in three principal service categories: long-range or intercontinental services; medium-range or regional services; and local service or interurban operations. All three have developed into an intertwining network of routes throughout the world that permit direct, convenient air-flight connections between all economically important points. The growth of this system has modified the travel habits of millions of people and has influenced sociological, political, and economic characteristics in many lands. These effects have been made possible not only by the rapid technological development of the transport aircraft itself but also by the introduction of uniform air navigational and communications facilities throughout the world, by a steady advance in flight safety, and by the progressive evolution of international air agreements, regulations, rules of flight conduct, and regulatory agencies that together provide a worldwide code of civil aircraft operation.

PRE-WORLD WAR II DEVELOPMENTS

International air transportation began on a large scale immediately following World War II when the long-range, four-engined aircraft emerged to pave the way for practical transoceanic flights. Prior to World War II, the British, Dutch, Belgians, and French inaugurated long-range air services to their colonial possessions in Africa and the Far East, but these services were possible only because of the availability of intermediate refueling points along the routes. Germany operated services to South America in the early 1930s and developed local air routes in Argentina, Bolivia, Brazil, Colombia, and Ecuador. In 1929 a U.S. commercial air carrier began regular service from Miami, Fla., to the west coast of South America and, in 1935, operated a transpacific service with flying boats, using a chain of islands as refueling and maintenance stops en route. The Germans began dirigible service between Friedrichshafen, Ger., and Recife, Braz., in 1932 and inaugurated transatlantic dirigible flights in 1936. By 1939 a regularly scheduled service using airplanes was available over the Atlantic. These beginnings were modest because of the operating limitations of transport aircraft available at the time. Engine power was low, payloads were restricted and operating ranges were circumscribed by limited fuel capacities. Maintenance facilities were haphazard at best and radio navigational aids were not available to any significant extent until the mid-1930s. These factors, together with dubious safety records, deterred many travelers from using air services. The first modern aircraft to achieve any notable degree of reliable performance and comfort was the U.S.-built Douglas DC-3, which entered commercial service in 1936. The DC-3 was an all-metal, twin-engined monoplane that could carry up to 21 passengers. The performance of this airplane attracted passengers in sufficient numbers to establish the pattern of air routes that constitute modern airways, and its reliability and generally excellent design tended to standardize airline equipment requirements subsequently.

United States.—Interest in air service lagged in the United States and it was not until 1926 that a regularly scheduled air service was founded with any real promise for the future. A number of experimental airmail flights were conducted in 1918, and in May of that year the Post Office Department began the first scheduled airmail service between Washington, D.C., and New York City. In 1924 the first scheduled transcontinental mail route was opened between New York City and San Francisco, Calif., and, also in 1924, the first regular night operations were conducted on the segment between Chicago, Ill., and Cheyenne, Wyo.

With the passage of the Kelly Act in 1925, the post office was authorized to contract with private operators for the transportation of mail, and within a year scheduled airline service within the United States had commenced. The Ford trimotor transport, an all-metal airplane with ten passenger seats, attracted some passengers but it was not until 1934, when Pres. Franklin D. Roosevelt ordered the cancellation of airmail contracts and directed the Army Air Corps to fly the mail, that the airlines showed any serious interest in passenger trade. The Army flew the airmail on a restricted basis only for a matter of months, and new mail contracts then were granted under competitive bidding to private operators in accordance with the Air Mail Act of 1934.

The reduced dependence on airmail revenues and the introduction of faster and larger aircraft brought about the dawn of passenger air transportation. The number of passengers flown by U.S. carriers was 5,782 in 1926; it rose to 461,743 in 1934; and had reached a total of 4,060,545 by 1942. The speed of the average transport airplane rose from about 110 mph in 1934 to about 158 mph in 1938, while the efficiency of aircraft utilization through improved maintenance increased during the late 1930s and costs per passenger-mile declined markedly. In 1934 the average seat capacity per passenger aircraft was 8; in 1938 the average had climbed to 12.7.

United Kingdom.—The British government recognized the commercial value of air transportation before the end of World War I and, following a report by the Civil Aerial Transport Committee under Lord Northcliffe in February 1918, created a Department of Civil Aviation within the Air Ministry on Feb. 12, 1919, under Maj. Gen. Sir Frederick Sykes. By the beginning of 1920 there were three British companies operating air services across the English Channel to Paris, Brussels, and Amsterdam, carrying passengers, freight, and mail. Success was limited and the carriers, in stiff competition with continental airlines, suffered financial loss. Government subsidy, totaling £105,000 in 1922, failed to rescue the carriers and, in 1923, the Hambling Committee was appointed to review the nation's civil air policy. It recommended that the four leading British airlines should be consolidated into a single, subsidized carrier for overseas air services.

The result was the organization of Imperial Airways, Ltd., established on April 1, 1924. One of the main tasks of Imperial Airways was the development of air routes to the Commonwealth countries, an important aspect of which was the transportation of empire airmail, under a provision guaranteeing an assured load of mail, carried at regular postal rates between the various countries. In 1927 Imperial Airways took over from the Royal Air Force the mail route between Cairo and Baghdad. The route was extended to Karachi, Pak., in 1929, and by 1935 Imperial Airways was operating throughout India and to Burma, Malaya, and Brisbane, Austr., a route distance of 12,754 mi. from London. Singapore was connected with Hong Kong in 1937, and a route was surveyed through Africa from the Mediterranean to the Cape of Good Hope.

While Imperial Airways was extending its routes, a number of independent, unsubsidized companies also were operating services to the continent and within the United Kingdom, but most of them were unable to work at a profit. In 1935 the Fisher Committee, therefore, recommended the formation of a second carrier to develop services to Europe. British Airways was formed for the purpose, but the government's policies caused so much dissatisfaction in civil aviation circles that a new committee under Lord Cadman was set up in 1937 to report on the whole situation. It was decided to create a single public corporation officially financed and responsible for all British overseas air services. This new instrument, British Overseas Airways Corporation, was formally established on Nov. 24, 1939, but by this time World War II had begun and the new corporation was placed under the operational control of the Air Ministry for the duration of the war.

Europe.—In Europe, as well as in Great Britain, an overabundance of services in relation to demand prevented the airlines from earning a profit. A large number of airlines were organized between 1920 and 1930 in response to demands for flag carriers to bolster national prestige, trade, and commerce. There were two results of the heavy competition: the merger of a number of airlines within individual countries, as in the case of Great Britain and France, and the creation of cartels by companies of different nationalities as a means of coping with high operating costs on highly competitive routes. One example of the latter arrangement was the organization of Deruluft, an international carrier established in 1921 by a German airline and the Soviet government.

In France the government early recognized the commercial value of air transportation; by 1931 French airlines were flying as far east as Indochina and virtually all of France's colonial possessions were connected with Paris by air routes. However, a large number of airlines, operating without a coordinated and regulated policy, suffered heavy losses during the 1920s and retarded the orderly growth of a national airline system. In 1933 five airlines finally merged to form the Compagnie Nationale Air France, which became the nationalized airline following World War II. Meanwhile, a number of smaller carriers continued throughout the 1930s to serve routes not covered by Air France.

Germany was particularly active in the development of an airline system prior to World War II, and between 1915 and 1926 had organized a total of 30 airlines, all but 6 of which were controlled by 2 air transport combines, Junkers Luftverkehr and Deutsche Aero-Lloyd. Because of the intense competition between the two groups, the government forced a merger in 1926 to form Deutsche Lufthansa. With the rise of the Nazi regime the airline became a political instrument and was used, among its other activities, as a device to penetrate South America. It established many subsidiaries throughout the world and held a one-third interest in Eurasia Aviation Corporation, founded in 1930 under German-Chinese auspices. By 1939 Deutsche Lufthansa routes covered Europe and extended to many parts of Asia and South America.

In the Netherlands KLM (Royal Dutch Airlines) was organized with government aid in October 1919 by Albert Plesman. After establishing a network of European services, it organized links with the Dutch East Indies and colonial territories in the Caribbean area.

In 1923 Belgium formed a national airline, Société Anonyme Belge d'Exploitation de la Navigation Aérienne (Sabena), which operated until Belgium was invaded by the German Army in 1940. It resumed operations after the war.

WORLD WAR II DEVELOPMENTS

It was the participation of the airlines in World War II that gave the industry the impetus it needed to make the potential of air transportation a reality. During the war commercial aviation came to a virtual standstill but the aircraft and the airlines' experienced personnel were pressed into military service to provide an air transport service that covered every major theatre of war. Regular service was launched across the North Atlantic, through the Pacific, over the Himalayas from Burma to China, into the Arctic regions, across Africa, and throughout Latin America. Efficiency of performance, never before attained, kept these long-range flights transporting troops and matériel on a regular basis. World War II revealed the real potential of the transport airplane and, just as important, it familiarized thousands of servicemen with the advantages of air travel.

POST-WORLD WAR II DEVELOPMENTS

The four-engined transport airplane was introduced commercially immediately after World War II and, beginning in 1946, the pressurized cabin, which maintained a near-normal air density

even while the aircraft was flying at high altitudes, came into widespread use. Navigational facilities were improved and all-weather operation became a reality. Speeds were increased up to 370 mph, seating capacity reached as high as 100 per airplane by the early 1950s, and the increased range of the new airplanes provided travelers with a wide variety of nonstop schedules between major cities. At first these innovations, as well as such travel inducements as reduced fares, did not attract passengers in the volumes originally anticipated by the airlines, and an overexpansion resulted that led to new deficits from 1947 through 1949. However, by 1950 passenger and freight traffic began to make notable gains, spurred to some extent by increased travel requirements brought about by the Korean War. Nonstop flights between New York and the West Coast of the United States were inaugurated in 1953 with the long-range Douglas DC-7 and, later,

BY COURTESY OF AERO SPACELINES

SUPER GUPPY, DESIGNED TO TRANSPORT LARGE AEROSPACE EQUIPMENT, HAS 25-FT. MAXIMUM INSIDE DIAMETER AND 49,790 CU.FT. OF CARGO SPACE. WAS BUILT BY COMBINING BOEING 377 AND C-97J AIRFRAMES, AND IS POWERED BY FOUR PRATT AND WHITNEY TURBOPROP ENGINES

nonstop flights with this airplane and the Lockheed 1049 (Super Constellation) were conducted between New York and Paris, London, and Lisbon. During the 1950s air transport developed into one of the world's most significant industries and was accepted as a common mode of transportation; on the North Atlantic routes it surpassed steamships in the number of passenger-miles traveled.

Regional Services.—Growth of long-haul travel was accompanied by an equally successful development of regional or medium-haul airline services. Expansion of this type of service was particularly marked in North and South America and Europe. From 1955 it grew rapidly in the U.S.S.R. and China, and notable progress with regional airline services was made in India and the Middle East countries. In the U.S.S.R. and China the Soviet-built Ilyushin Il-14 was used extensively for this service, while in other countries of the world the British-built four-engined Vickers Viscount, the Fairchild/Fokker F-27, and the Nord 262 turboprops and the twin-engined U.S. Convair 440 and Martin 404 were widely used on medium-haul schedules. By the mid-1960s jet aircraft such as the Douglas DC-9, Boeing 737, and BAC-111 were in general use in regional services.

Helicopter Services.—Helicopters serving large metropolitan areas began to make their appearance in the postwar years, but, because of the helicopter's relatively high cost of operation and restricted payload, progress initially was slow. By the 1960s helicopter services were playing a significant role in some areas, but scheduled flights by rotor planes were still not being made on a large scale. In Belgium Sabena eliminated its Brussels helicopter services in 1965 because of high operating costs; British European Airways operated scheduled helicopter flights in the United Kingdom; and, in the United States, New York, Chicago, Los Angeles, and San Francisco were served by active helicopter airlines that linked trunk-line airports with suburban communities. In the U.S.S.R. helicopter schedules flown with Soviet-built rotor planes (notably the Mi-4) began in 1958 to serve such intercity routes as that between Simferopol and Yalta. The U.S.S.R. also used the helicopter to provide transportation to hard-to-reach areas of the Urals, Siberia, Central Asia, and Kamchatka.

Feeder Airlines.—Feeder or local-service airlines sprang up in many parts of the world during the early postwar years and grew rapidly in favour as a necessary link between trunk-line hub areas and smaller cities. Many local-service airlines used the Douglas DC-3, but by the mid-1960s a number of the small carriers in the United States had replaced these with turbine-powered aircraft.

All-Cargo Airlines.—A number of all-cargo airlines—carriers confined to the movement of freight and sometimes mail—were organized in the years immediately following World War II, but by the 1960s they had declined in many areas. The survivors met with remarkable success after introducing jet all-cargo aircraft. Cargo operations were particularly successful in Latin America, and by the 1960s they were also being conducted extensively in the U.S.S.R. In countries where highways and railways were not fully developed, cargo flying showed particular promise.

Nonscheduled Airlines.—Nonscheduled or supplementary airlines—carriers devoted to the movement of special groups of passengers on charter or to the operation of flights without reference to published schedules—flourished during the early postwar years and by 1950 posed a serious competitive threat to the scheduled airlines. In the United States, however, the scheduled lines inaugurated reduced fares that matched the lower rates of the nonscheduled operators and the latter had substantially dwindled in size by the 1960s. Later, as in the case of all-cargo airlines, jet aircraft bolstered the fortunes of the nonscheduled lines.

Reduced-rate operations, however, remained especially successful in Latin America, where the large number of airlines made competition especially keen. In the United Kingdom the nationalized airlines were in competition with private operators who were able to offer transportation on certain routes and for certain classes of traffic at fares well below those established as standard by the scheduled airlines. In France, Air France also encountered serious opposition from some of the larger private airlines. Competition between charter airlines and the Scandinavian Airlines System consortium grew particularly keen in the 1960s on the routes from Norway, Sweden, and Denmark to the Mediterranean resort areas.

THE JET AGE

The introduction of jet aircraft reinforced the growth of air transportation to a significant degree. Because of the high speed of these aircraft (each new type approached nearer and nearer the speed of sound) as well as the greater passenger comfort inherent in jet flight, *e.g.*, lack of vibration and relative quiet, the pure jet (turbojet) was an immediate success with the traveling public.

The first jet airplane to make its appearance on commercial routes was the British de Havilland Comet. Comet service began in 1952 on the routes of British Overseas Airways Corporation, but two serious accidents in 1954 led to the grounding of the aircraft. Investigation of the accidents disclosed metal fatigue to be the cause, and an intensive modification program designed to correct the fatigue problem was conducted. Comets were flying again in 1955 and were reintroduced into commercial service in the fall of 1958.

Soviet Airlines.—Aeroflot, the Soviet airline, began pure jet service in 1956 with the twin-engined Tu-104, which was later modified to accommodate 100 passengers. In addition, Aeroflot in the 1960s was operating the An-10, An-16, An-24, Il-18, Il-62, Tu-114, Tu-124, and Tu-134. Coincident with the achievements of the airline, the U.S.S.R. eased its policy of isolationism in commercial aviation and negotiated bilateral air transport agreements with a number of European, Near Eastern, and Far Eastern nations. By the 1960s Moscow was linked by air with the capitals of a number of non-Communist countries, including New Delhi, Cairo, Paris, London, Brussels, Copenhagen, and Amsterdam. Within the U.S.S.R. turbojet and turboprop aircraft were operating into the Ukraine, the western U.S.S.R., and Siberia. Jet flights were conducted on a scheduled basis to Murmansk and Norilsk, well above the Arctic circle. A two-track system on the trans-Siberian route to permit flying around bad weather afforded the airline an opportunity to fly more regularly on this route, which extends from Moscow through Sverdlovsk, Omsk, Novosibirsk, and

on to Irkutsk and Vladivostok. Another major route on which turbine equipment was introduced in 1960 was that running from Irkutsk to Alma-Ata and from Khabarovsk to Magadan. A shuttle service conducted between Leningrad and Moscow was so popular that in one six-month period traffic increased 1,000%. In 1967 the Soviet Union opened its trans-Siberian routes to flag carriers of other nations: first to Japan Airlines and then to the Scandinavian airlines system on the Moscow–Tokyo route.

United States Airlines.—In the United States the first pure jet service with the Boeing 707 transport was started on the North Atlantic route by Pan American World Airways System, and American Airlines began domestic operations on its coast-to-coast route with the same type of airplane in January 1959. The first turbine service in the United States was started by Capital Airlines (which later merged with United Airlines) in 1955 with the Vickers Viscount turboprop transport. The Lockheed Electra turboprop was placed on commercial routes in early 1959 and was followed by a larger version of the Boeing 707, the Douglas DC-8, the Convair 880, the Convair 990, the Boeing 720, Boeing 727, French-built Caravelle, British-built BAC-111, Douglas DC-9, and the Boeing 737, all pure jet aircraft.

The U.S. domestic routes by the 1960s were served by 11 carriers, each of which operated turbine as well as piston-engine aircraft. Of these carriers, 7 also operated international routes, the most extensive services being Braniff International Airways to South America, Northwest Orient Airlines across the Pacific Ocean by way of Alaska, and Trans World Airlines across the Atlantic Ocean to Europe and the Far East. Pan American World Airways System had no domestic routes, except to Alaska and Hawaii, but served a system that, except for the gap in the central United States, included a round-the-world route and routes into South America and Africa. Pan American-Grace Airways, known as Panagra, was merged into Braniff in 1965. Seaboard and Western Airlines, Inc. operated an all-cargo service between the United States and Europe. There were 23 local service carriers in the United States, including 8 in Alaska and 2 in Hawaii, as well as 4 scheduled helicopter airlines and 3 domestic all-cargo airlines. Several carriers with permission to fly all-cargo services had withdrawn from active operations by 1960. Twenty supplemental airlines were authorized to conduct a maximum of ten round-trip flights each month between any two points.

United Kingdom Airlines.—In Great Britain, British Overseas Airways Corporation in 1960 inaugurated Boeing 707 service and later supplemented this fleet with the Vickers VC-10 and Super VC-10, as the de Havilland Comet and Bristol Britannias were retired. Pure jet service was offered by the corporation to six continents: Montreal–London and New York–London; London through the Near East to India, Hong Kong, and Tokyo; London to Australia and South Africa; London to South America; and New York to Nassau and Jamaica. Britain's second nationalized corporation, British European Airways, operated an all-turbine-powered fleet of aircraft on its external routes as early as 1958, the first of the world's airlines to achieve this. In 1960 the airline introduced the large Vickers Vanguard turboprop transport but later added the Hawker Siddeley Trident jet transport to its fleet for blue ribbon services.

Other Airlines.—The Belgian airline, Sabena, began the operation of Boeing 707 pure jets across the Atlantic in 1960 and jet services to Léopoldville (now Kinshasa) and Johannesburg later that year. Boeing 707 flights were also operated on the route to Moscow, and later the airline placed the French-built Sud Caravelle turbojet transport on its medium-range routes. Lufthansa of West Germany also began transatlantic service with the Boeing 707 in 1960 and later that year started polar-route flights between San Francisco and Frankfurt with the same airplane. Air France began using the Boeing 707 on its transatlantic flights and on the polar route Paris–Anchorage–Tokyo. Air France also operated the Sud Caravelle on its medium-range routes. A private firm, Union de Transports Aériens (UTA), formed by a merger of TAI and Union Aéromaritime de Transport, operated DC-8 jets. KLM, flag carrier of the Netherlands, started flying the DC-8 in 1960, as did Iberia Airlines of Spain. Scandinavian Airlines System—a consortium flag carrier representing Denmark, Norway, and Sweden—operated the Douglas DC-8 between Copenhagen and New York and over its polar route, Copenhagen–Anchorage–Tokyo, beginning in 1960. The same year Air-India International, flag carrier for India, began jet service over two routes: New York–London–Paris–Rome–Cairo–Bombay and New York–London–Frankfurt am Main–Geneva–Beirut–Bombay–Calcutta. Ja-

pan Air Lines began transpacific jet service with the Douglas DC-8 in the summer of 1960 and, in South America, Aerolineas Argentinas, the Argentine airline, put de Havilland Comets into service between Buenos Aires and New York and on its South Atlantic route to Europe. Varig Airlines of Brazil flew the Sud Caravelle between New York and Rio de Janeiro, Brasília, and Saõ Paulo. In Canada both Canadian Pacific Airlines and Trans-Canada Airlines were operating the Douglas DC-8 on major routes by 1960. Canadian Pacific also used the Bristol Britannia turboprop transport, and Trans-Canada operated the Vickers Viscount turboprop on its medium-haul routes. Qantas Empire Airways, Ltd. of Australia was operating its round-the-world route with the Boeing 707 by 1960.

Problems Accompanying the Changeover.—The revolutionary transition from piston-engine power to the jet age was accomplished with remarkably little difficulty, but there were problems. Operating costs began to climb and, because of the high seating capacity of the pure jet and its ability to fly twice as far in a normal workday as the fastest piston-engine plane, the available passenger service outstripped normal passenger traffic growth; it became difficult to maintain satisfactory payloads. The initial cost of the equipment was high—up to $6,500,000 per airplane—and new ground equipment, larger terminal buildings, and higher training costs added to the financial burden of an industry that had always contended with a narrow earnings margin. Smaller airlines, unable to undertake new equipment programs, suffered a serious competitive disadvantage.

Gradually, however, plans and programs evolved that softened the pressure of these problems. A differential in passenger rates was agreed upon in 1959, permitting some underdeveloped carriers, particularly in South America, to charge lower fares than those charged by financially stronger carriers, thus allowing them to attract the economy-minded passenger. Consortiums were formed to allow carriers to pool equipment, expenses, and maintenance, the most notable being Air Union, comprised of Air France, Alitalia of Italy, Sabena of Belgium, and Swissair of Switzerland. British European Airways reached a consortium agreement with Olympic Airways of Greece in 1960, and the major airlines of the British Commonwealth formed a pooling system in 1959. In South America as many as 70 airlines were serving the continent in the 1960s, and heavy competition forced deficits on a number of them. In some instances they were kept from foundering by financial aid from their governments, which were anxious to maintain flag carriers for national prestige.

By the mid-1960s, it had become evident that as a result of an expanding acceptance of air travel and the popularity of the jet aircraft, the airlines of the world had entered an era of prosperity. The majority of leading airlines placed large volumes of new orders for jet aircraft to meet the growing demand from the public. The new models were designed to serve all categories of air transportation and were responsible for an almost complete transition from piston-engine to turbine-powered planes.

British Aircraft Corporation introduced the Super VC-10 for long-range operations and the BAC-111 for short-haul services. In the U.S., Douglas Aircraft Company offered the DC-9 and Boeing designed the 737 jet aircraft for short-range operations. At the same time, both Boeing and Douglas increased the size of their 707s and DC-8s to accommodate more passengers. The Soviet Union followed a similar pattern in providing transport aircraft for the state-owned airline, Aeroflot, but had small fortune in finding an export market for its planes despite this increase in inventory. During the mid-1960s the U.S., the Soviet Union, and, working together, Britain and France began to develop supersonic transport airliners that would be capable of flying 2–2½ times the speed of sound.

Many airlines of underdeveloped nations received technical assistance not only from the governments of stronger nations but from the larger airlines as well. Trans World Airlines lent technical aid to Ethiopian Air Lines and Saudi Arabian Airlines, and Pan American World Airways System was active in establishing air service within Afghanistan. The Export-Import Bank issued large loans during the jet reequipment period to help foreign flag carriers buy new aircraft. The U.S. government's International Cooperation Administration, in conjunction with the Federal Aviation Agency, helped to establish airways and navigational systems in countries unable to cope with the technicalities of modern air navigation. Major nations in Europe made equally important contributions to the development of air transportation in the jet age.

INTERNATIONAL REGULATION OF AIRLINES

Generally, the transition to turbine power in commercial service was accomplished in an orderly manner, and the standards of operation, airworthiness, and service that had distinguished the growth of civil aviation after World War II were maintained despite strong national differences on a number of major issues. The fact that these differences did not disrupt growth at this vital stage of airline development was the result of international agreements controlling the operation of the whole system of airlines and the cooperation of regulatory agencies of the individual governments.

Air transportation is conducted on the internationally accepted principle that each nation has a sovereign right to the air above it. This concept, so different from the "freedom of the seas" code that directs maritime policy, necessitated a series of agreements that would respect this air sovereignty yet permit commercial "freedom of the skies." The agreements that emerged from various conferences are not treaties and therefore do not constitute international law. Thus an agreement between two nations for air services can normally be broken off merely by the announcement by either of the parties that it intends to do so upon the expiration of a previously agreed interval.

Although the first conference to establish some type of air law was held in Paris in 1889, no real progress toward international regulation in the conduct of air transportation was made until after World War I. Participants in the Paris Conference of October 1919 agreed that private aircraft should be permitted to fly over the territories of the participating states, but this permission was not extended to the aircraft of commercial airlines offering scheduled service.

During the next 20 years development of international air transportation progressed through bilateral rather than multilateral agreements. Pan American World Airways System was able to negotiate unofficially with a number of South American countries for the expansion of air routes from the United States throughout South America. Imperial Airways of the United Kingdom expanded its routes through the use of airports in colonial possessions and Commonwealth nations. The French, Dutch, Belgians, and Germans developed international routes in a similar manner. Generally, however, the common method of establishing routes between nations was a bilateral air transport agreement granting operating rights and traffic privileges to the airlines of the nations involved. By the 1960s there were approximately 500 bilateral agreements in effect throughout the world.

During World War II the real significance of international air transportation became clear, largely as a result of the experience gained in the worldwide military airlifts operated by the various belligerents. It was obvious that some agreement was needed to permit the orderly development of postwar air routes without infringing upon sovereign air rights. At the same time provision had to be made for a controlled form of competition that would prevent large airlines from destroying smaller ones. In addition, it was realized that certain standards were needed for airworthiness of aircraft, qualifications of flying personnel, and specifications for navigation and air traffic control.

Chicago Convention.—At the invitation of the United States, representatives of 54 nations met at Chicago on Nov. 1, 1944, for the purpose of reaching some agreement that would provide for the control of air transportation and, at the same time, foster its development. During the conference a serious difference of view appeared between the United States and the United Kingdom, the latter being supported by a number of other European countries. The U.S. favoured a policy of free competition based on complete freedom of the air, while the Europeans wished to impose certain conditions designed to eliminate wasteful competi-

tion and ensure to individual countries an equitable share of the traffic through their own air space. Between these divergent points of view the conference failed to reach agreement.

The International Air Transport Agreement that incorporated the U.S. doctrine of complete freedom is of particular interest, though it failed to obtain the adherence of more than ten countries and was soon denounced by the U.S. government itself, largely because of criticism at home. It set forth for the first time the "Five Freedoms of the Air," the granting of some or all of which formed the basis upon which all bilateral air agreements between pairs of countries subsequently were negotiated. These freedoms are (1) the right to fly across the territory of a foreign country without landing; (2) the right to land for nontraffic purposes, *i.e.*, to refuel or obtain mechanical attention; (3) the right to discharge in a foreign country traffic coming from the home country; (4) the right to pick up in a foreign country traffic destined for the home country; and (5) the right to carry traffic from a point of origin in one foreign country to a point of destination in another foreign country. Traffic, in all cases, refers to passengers, mail, and cargo. (The right to pick up traffic at a point within a foreign country and carry that traffic to another point in the same country is termed "cabotage" and is generally banned by all nations.)

The International Air Services Transit Agreement, on the other hand, called for the mutual exchange of only the first two freedoms. This was more readily acceptable to the delegates to the Chicago Convention, and only ten of the nations represented failed to ratify it. Failure to reach multilateral agreement on the overall principles of air transportation might be taken as an indication that the conference was unsuccessful. Nevertheless, many solid achievements emerged, notably the drafting of a new civil aviation convention to supersede those of Paris (1889) and Havana (a Pan-American civil aviation convention signed in 1928). The groundwork was laid for the formation of an international airline system embracing all views without creating conflicts that would prevent general cooperation in air transportation or a worldwide linking of routes to permit an easy flow of traffic between nations.

International Civil Aviation Organization.—The principles developed under this agreement are administered by the International Civil Aviation Organization (ICAO), which was founded by agreement of the Chicago Convention and which came into being on April 4, 1947, with permanent headquarters at Montreal. This organization, which is charged with coordinating and administering all aspects of international civil aviation, consists of these component bodies: (1) an assembly of delegates from all member nations; (2) a council of representatives of 21 member states, which is elected by and is responsible to the assembly and which sits in continuous session at the headquarters of the organization; (3) an air navigation commission appointed by the council from among persons nominated by member states; and (4) an air transport committee also appointed by the council, but made up of representatives of council member states. The members of both the commission and the committee devote full-time membership to their respective bodies.

Other committees were established by the assembly, including the Legal Committee and the Committee on Joint Support of Air Navigation Services. The legal committee, which replaced the Comité International Technique d'Experts Juridiques Aériens (CITEJA), is concerned with the study and drafting of conventions in the field of air law and with cooperation with other organizations in the codification of international law. One of its achievements is the Convention on International Recognition of

Rights in Aircraft, which is designed to protect the interests and rights of contracting states in their own aircraft crossing international borders. The Committee on Joint Support of Air Navigation Services advises the assembly on requests from member states for technical and financial assistance in the field of air traffic control.

In the 1960s ICAO had a number of international agreements to ensure cooperation in the performance of navigational functions. Floating sea stations, owned or financed by a number of nations, were maintained in the North Atlantic for communications and weather-reporting services.

Two loran (long-range radio navigation) units were financed through ICAO agreements, one located in Iceland, the other in the Faroe Islands.

ICAO established and periodically reviews standards for air transportation on a worldwide basis. These standards cover licensing of personnel, airworthiness of aircraft, aeronautical charts, meteorological codes, registration of aircraft and identification markings on aircraft, rules of the air, accident investigation, airports, communications, facilitation (immigration and customs), and air traffic control and navigation.

ICAO has ten regions, each of which conducts regular meetings to consider problems peculiar to the region. These regions are the North Atlantic, European-Mediterranean, Middle East, Caribbean, South Pacific, South America, South Atlantic, Southeast Asia, North Pacific, and Africa-Indian Ocean. Although ICAO membership is not universal, the 74 member nations operate 90% of all international airlines.

The Hague and Warsaw Conventions.—Two other widely accepted agreements, dating from many years before the Chicago Convention but of continuing importance in the regulation of international civil aviation, are worthy of note. First, the International Sanitary Convention on Air Navigation, originally signed at The Hague in 1933 and brought up to date at New York City in 1946, gave the right to each contracting party to impose upon the aircraft of other contracting parties entering its territory certain measures designed to prevent the spread of communicable diseases. Next, the Warsaw Convention, which was originally signed in 1929 and which had received general agreement by 1960, was concerned with the liability of air operators for damage to persons or property in international air transportation. It also contained provisions relating to the form and legal effects of air transport documents, including baggage and passenger tickets and air waybills. In 1965 the two conventions were drastically revised by a substantial increase in maximum liability ceilings for damage.

International Air Transport Association.—In April 1945 the new International Air Transport Association came into being and was given wide authority to fix rates and fares subject to the approval of the governments involved. Headquarters were established in Montreal and membership came to include most of the world's airlines. Meetings are scheduled annually. Biannual conferences are held by the Traffic Conference, which establishes rates subject to governmental approval.

Bermuda Agreement.—One of the most significant of the bilateral air transport agreements was that signed between the United Kingdom and the United States at Bermuda in 1946. Known as the Bermuda Agreement, this pact became the prototype for a large majority of the other bilateral agreements signed in the following years. The Bermuda Agreement represented a compromise between the policies of the United Kingdom and the United States. It incorporated the Five Freedoms but placed curbs on their application through the introduction of capacity clauses. In effect, these clauses prevent overscheduling and relate schedule frequency and seat capacity to public demand on the routes exchanged.

The Bermuda Agreement opened the way for additional bilateral agreements, and by the 1960s virtually every nation of the world was either operating air services or was served by a foreign airline. Even such small nations as Burma, Ghana, Iran, South Korea, and Lebanon had signed bilateral agreements with larger nations and were operating flag carriers.

INTERNAL REGULATION OF AIRLINES

The International Air Transport Association is a self-governing organization, voluntarily operated by the airlines. The International Civil Aviation Organization is an arm of the United Nations and is directed by member governments. Within each country civil aviation is usually government-regulated.

British Commonwealth.—In the United Kingdom the Ministry of Transport and Civil Aviation lays down civil aviation policy and directs the operation of British Overseas Airways Corporation and British European Airways, which were nationalized under the Civil Aviation Act of 1946. In 1951 greater freedom was granted independent airlines, and by 1955 the number of privately owned carriers in the United Kingdom reached 40. In Australia the control of civil aviation is under the jurisdiction of the minister for air. Canada regulates civil aviation through the air services branch of the Ministry of Transport. The national carrier is Trans-Canada Airlines, which was organized by act of Parliament in 1937. In 1947 the airline took over the operation of transatlantic services, which previously had been the responsibility of the government. In 1959 Trans-Canada lost its monopoly on Canada's domestic routes when Canadian Pacific Airlines was granted competitive routes across the continent.

Europe.—In France the nationalized airline, Air France, competes on a number of routes with two privately owned carriers—Transports Aériens Intercontinentaux and Union Aéromaritime de Transport. The airline of the Federal Republic of Germany, Lufthansa German Airlines, has its ownership divided between the federal government (92%) and the states (8%), while the airline of the German Democratic Republic, Interflug, is totally controlled by the central government. Belgium's airline, Sabena, is 50% privately owned, with the balance owned by the Belgian government. The Netherlands government owns more than 96% of its flag carrier, KLM. The Scandinavian Airlines System (SAS) consists of a single operating company in which Sweden holds three-sevenths and Norway and Denmark two-sevenths each of the capital. Italy reentered the field of civil aviation after World War II with two airlines, but in the late 1950s these were amalgamated into a single company, Alitalia, with substantial governmental participation. In Spain and Portugal similar subsidized airlines, known as Iberia and Transportes Aereos Portugueses (TAP) respectively, concentrate mainly on serving their colonial possessions and South America in addition to their European networks. In the U.S.S.R. civil aviation was organized as a government department under the general title of Aeroflot, while each of the Soviet Union's European satellites possesses a national air carrier.

Asia.—In Communist China the government operates the Civil Aviation Service, while the flag carrier serving the Chinese Nationalist government in Formosa, Civil Air Transport, is Chinese-owned but operated under U.S. management. Japan Air Lines is partly government-owned and is required to obtain governmental approval for large expenditures such as the purchase of new aircraft. Air Ceylon, Ltd., provides services within the island and connections to the Indian peninsula, where three officially regulated airlines operate—Air-India International and Indian Airlines Corporation in India and Pakistan International Airlines in Pakistan. Thailand and Vietnam each possess government-subsidized air carriers. Egypt is represented by Misrair and Israel is served by the state-owned flag carrier El Al (El-Al Israel Airlines). In Turkey the state airways administration operates a domestic air service.

United States.—U.S. airlines are privately owned. The Civil Aeronautics Board regulates rates and routes on domestic operations, and the Federal Aviation Agency maintains and operates the U.S. airways system and has jurisdiction over safety regulations. The president of the U.S. gives final approval of all U.S. bilateral agreements, which are negotiated by the U.S. Department of State.

GENERAL AVIATION

The term general aviation is often used to describe all types of aviation except military applications and commercial air trans-

BY COURTESY OF BUSINESS JETS

A PRIVATELY OWNED FANJET PLANE USED FOR BUSINESS TRAVEL

port. Among the major activities included within the scope of general aviation are business, charter, survey and patrol, agricultural, instructional, and pleasure flying. In the 1960s about 60% of the world's airplanes were engaged in general aviation; the types of planes used ranged from large multiengine airliners to light single-engine craft capable of carrying only one or two passengers.

One of the fastest growing branches of general aviation was that of business flying; in the mid-1960s more than 50% of the total hours flown annually in general aviation were in business aircraft. Many large companies purchased one or more aircraft for use by their officials, thereby gaining the advantage of increased flexibility as compared with previous dependence on scheduled airliners. Business planes were often two-engine models capable of accommodating eight to ten passengers.

Chartered or rented aircraft ranged from multiengine airliners used for passenger and cargo transportation to light single-engine planes. Aircraft were chartered for a variety of purposes, among the most prominent of which were aerial mapping and photography, mineral prospecting, pipeline patrolling, forestry patrolling, and advertising.

Airplanes were used frequently by farmers and ranchers for spraying and dusting crops and for seeding and fertilizing land. Aircraft employed for those purposes were often rented, but some farmers purchased their own planes. Most agricultural aircraft were light single- or twin-engine models that had been adapted for their mission by being equipped with storage tanks and spray booms for spraying and with bins and blowers for dusting. These planes were also occasionally used to spray hordes of destructive insects, such as locusts.

Instructional and pleasure flying in the 1960s together accounted for about 35–40% of the annual hours flown in general aviation. Aircraft used for these purposes were usually light single- or twin-engine models. A branch of pleasure flying that maintained its popularity was aviation sports, which included racing, stunt flying, and endurance competitions. Related sports that gained in popularity during the 1950s and 1960s were gliding and soaring, and skydiving (sport parachute jumping).

AVIATION, HISTORY OF. The general purpose of this article is to give a condensed survey of man's conquest of the air. It is not intended to cover the theoretical aspects of flight but to place in proper perspective the various kinds of aircraft that have been developed—from the first balloon to the supersonic bomber.

A few definitions are first in order. The word aviation in its modern usage refers generally to the art of flying. During the latter half of the 19th century the terms flying, aeronautics and aerial navigation were used more or less synonymously to cover any effort of man to fly through the air. The words aviation and aviator, both of French origin, first appeared in the literature of the mid-1880s. They did not achieve general acceptance, however, until about the time of World War I. By about 1914 they were generally used in connection with heavier-than-air flight, and the terms aeronaut and aerostat were used to describe lighter-than-air pilots and their equipment.

In Great Britain the term aeronautics first appeared in vol. 1 of the 1824 Supplement to the *Encyclopædia Britannica* to describe the art of flying in general. As late as the 1920 edition of *Jane's All the World's Aircraft* reference was made to the "development of naval and military *aeronautics*." In the same edition, however, there was a reference to "civil *aviation*." By the 1922 edition *Jane's All the World's Aircraft* had dropped the word "aeronautics" and had adopted the subtitle "Notes on the Development of Naval and Military *Aviation*."

Charles Dollfus and Henri Bouché, in their *Histoire de l'aéronautique* (1932), describe Dec. 17, 1903 (the date on which the Wright brothers first flew a powered heavier-than-air craft), as the beginning "*de l'histoire de l'aviation*," and go on to say that "*l'aviation*" was born in France between 1904 and 1910.

Thus, as it is commonly used, the word aviation generally refers to the operation and usage of heavier-than-air flying machines, but it is also applied to operation of lighter-than-air equipment; *i.e.*, balloons and airships. In the present article the important landmarks and events in lighter-than-air flight will also be noted. Principal concern, however, will be with those classes of aircraft whose flight depends upon the dynamic reaction of lifting surfaces (or wings) and the atmospheric air flowing over and around them. Additional information on the history of lighter-than-air flight is contained in the articles AIRSHIP and BALLOON FLIGHT.

For convenience in this discussion, aviation history is divided into five main periods: (1) prehistoric—prior to 1783; (2) exploratory—between 1783 and 1903; (3) trial and error—1903 to about 1914; (4) practical development—World War I to World War II; (5) accelerated development—World War II and after. Actually, only the first two of these five periods are definitive. The last three cannot be differentiated by sharp lines of demarcation; they merge in shadow zones which extend over several years in either direction.

For the purposes of this article, the placing of objects into orbit around earth is not considered to be an aviation activity. It is true that to reach outer space, and to return to earth safely, flight through earth's atmosphere is necessary. Some form of aerodynamic support or control is involved in this portion of the flight. But the true space vehicle differs markedly from the airplane or airship. (*See* SPACE EXPLORATION.)

The presentation of topics in this article is as follows:

I. Prehistoric Period
II. Exploratory Period (1783–1903)
III. Period of Trial and Error (1903–14)
IV. Period of Practical Development (1914–40)
V. Period of Accelerated Development (1940–)

I. PREHISTORIC PERIOD

From time immemorial man's aspirations seem always to have been directed upward. He has thought of his blessings as descending from *above*—and to reach heaven the souls of the departed must fly *upward*. Many of the old religions clothed their celestial beings in birdlike forms. Ancient Egyptian and Greek deities wafted through the air without benefit of wings, or, like Mercury, with an embryonic pair sprouting from their heels. The ancient seraphim and cherubim of the Hebrews, and the heavenly hosts of later dispensations, have all been provided with wings.

It was not surprising, therefore, that when man first thought of translating his dreams into actualities, he began to study the flight of birds. He soon realized that, although it looked amazingly easy, a practical solution of the problem was going to be exceedingly difficult. In fact, after several hundred years of speculation, computation and experiment, no man-carrying wing-flapping machine (ornithopter) has ever been built. The combination of high structural strength, light weight and energy-conversion capability that exists in even the smallest bird has never been duplicated by any man-made contrivance. Late in the 15th

century Leonardo da Vinci made sketches and built models of birdlike machines, as have many people since his time. None has achieved even a modicum of success. However, research has been undertaken in the fields of ornithology and biology to try to determine how and why birds perform as they do. (*See* FLIGHT [NATURAL].)

A few people, at a very early date, observed that certain birds could soar, or could glide through the air without flapping their wings. John Wilkins (1614–1672), lord bishop of Chester, one of the founders of the Royal Society, observed that "if a bird can so very easily move itself up and down in the air without so much as stirring the wings of it, certainly then it is not improbable . . . that when men, by long practice, have arrived to any skill and experience, they will be able, in this, to come very near unto the imitation of nature." Actually, if more men had followed this line of thought and had abandoned the wing-flapping idea earlier, some form of heavier-than-air craft might have been achieved long before the Wrights flew. The real problem then, and continuing to the early part of the 20th century, lay in the lack of a lightweight power plant from which necessary propulsive force could be derived.

Several abortive efforts to make gliding flights are recorded between 1670 and 1780; however, shortly thereafter, with the appearance of the first hot-air balloon (1783), attention was focused in another direction; *i.e.*, toward lighter-than-air techniques.

II. EXPLORATORY PERIOD (1783–1903)

Free Balloons.—Late in 1782 the two Montgolfier brothers, sons of a paper manufacturer in the small town of Annonay near the centre of France, discovered that if they trapped a quantity of heated air in an inverted lightweight paper bag, the bag would float upward through the air. They had invented what shortly came to be known as the *glôbe aérostatique* or hot-air balloon. After the Montgolfier brothers made demonstrations with balloons of varying size, Jean François Pilâtre de Rozier and the marquis François Laurent d'Arlandes made the first man-carrying free balloon flight on Nov. 21, 1783. Their flight across Paris, nearly six miles, lasted about 25 minutes. In Dec. 1783 the newly discovered hydrogen gas was substituted for hot air in a balloon. The physicist J. A. C. Charles, accompanied by M. N. Robert, made the first manned flight using hydrogen. These four pioneers proved conclusively that man was no longer earthbound.

The history of the next 100 years is dotted with the names of balloonists and their exploits. The first great European balloonist, J. P. Blanchard, accompanied by an American physician, John Jeffries, crossed the English channel in a free balloon on Jan. 7, 1785. James Sadler, Vincenzo Lunardi, Francesco Zambeccari and many others made numerous flights in England and on the continent. By 1804 scientific exploration of the atmosphere was attempted by two French chemists, Joseph Louis Gay-Lussac and his assistant, Jean B. Biot. They reached an altitude of over 23,000 ft. in the course of their researches. They were followed by the retired dentist H. T. Coxwell who, with the scientist James Glaisher, claimed to have reached an altitude of about 37,000 ft. in 1862. Obviously, however, such an altitude could not have been attained without proper high-altitude breathing equipment (not then invented) and the claim must have been the result of faulty instruments, a misreading of the instruments under low-oxygen conditions (hypoxia), or both.

Early in the century the sport had spread to America. Blanchard made demonstration flights in Philadelphia in 1793 that inspired Charles Durant and John Wise to become balloonists. They made a number of long balloon flights in the United States between 1830 and 1875.

The use of balloons as observation posts in warfare was early recognized. The French army organized a balloon corps in 1789, which played a part in the battle of Fleurus in June 1794. After the first bombing raid in history (carried out by unmanned hot-air balloons sent by Austria against Venice in 1849), the most important early use of balloons in warfare was in the American Civil War, when T. S. Lowe, a disciple of Wise, built observation balloons for the "Aeronautic Department, U.S. Army." They were used by the Union army during the campaigns of 1862 and early 1863 to observe the movements of the Confederate army. Confederate forces also made limited use of balloons to observe Union troops. In 1870–71, during the Franco-Prussian War, about 70 free balloons were used to evacuate personnel and to carry mail out of the besieged city of Paris. Of comparable importance was the transport of carrier pigeons which returned to Paris with messages and letters.

Probably the most notable free-balloon enterprise of the latter part of the 19th century was the unsuccessful effort of Salomon Andrée and two companions to fly across the north pole. They took off from Spitsbergen, Nor., on July 11, 1897, and were not heard of again until, in 1930, entirely by accident, a Norwegian exploring party found the frozen bodies of Andrée and his two companions on an island north of Spitsbergen. As an interesting sidelight to this incident, photographic films which were exposed by Andrée and his party in 1897 were developed and provided a photographic record of the wreck of the balloon on the polar ice.

Except for intermittent use as a sports device (international

balloon races were first held in the early 1900s), free balloons had no great significance until they appeared many years later (1940 *et seq.*) as a means of scientific exploration on the fringes of earth's atmosphere. (*See* further BALLOON FLIGHT.)

Airships.—One other form of lighter-than-air craft became significant in the latter half of the 19th century—the dirigible balloon or airship. It early became obvious to Blanchard, Wise and others that little dependence could be placed upon natural wind currents to carry balloons to places where men were likely to want to go. Sails and oars had long since become commonplace for the propulsion and steering of waterborne vessels, but experimenters soon found that such devices were of little use in the air. All kinds of sweeps, and even hand-driven paddle wheels, were tried, but all proved impractical. The true airship had to await the development of a powerful, lightweight, self-contained engine that would be capable of driving large propellers continuously. It was not until the Frenchman Henri Giffard succeeded in building a three-horsepower steam engine which, complete with its boiler, weighed only 350 lb., that the first airship flight could be made. On Sept. 24, 1852, he took off from the Hippodrome in Paris and made a flight to a preannounced destination. Giffard's experiment led to the development of larger and more powerful airships. The first planned round-trip flight by airship was made on Aug. 9, 1884. Designed by two French army officers, Capts. Charles Renard and A. C. Krebs, this airship was powered by an 8-h.p. electric motor fed by heavy batteries.

The most colourful character involved in airship development in the late 1800s was the Brazilian-born Parisian Alberto Santos-Dumont. The full history of his work with airships is contained in his book, *My Airships*, published in 1904. Altogether he built 16 small airships, most of them powered with small, lightweight air-cooled motors, similar to motorcycle engines. He later switched his attention to heavier-than-air craft. All of Santos-Dumont's airships were of the nonrigid type. The elongated gas bag to which the pilot's car and the engine were attached maintained its shape solely because of the pressure of the gas inside. If the gas bag were punctured the whole container would collapse in a heap like any spherical balloon.

About 1900 the work of the great proponent of the rigid airship, Graf Ferdinand von Zeppelin, became known in Germany. Although most of Zeppelin's work took place in the third historical period (trial and error—1903 to 1914), it should be noted that the LZ-1 was built and flown from Lake Constance in 1900.

Cayley's Glider Experiments.—Although for many years most people believed that the only practical way for man to fly was by floating through the air in balloons or airships, the concept of a mechanical flying machine continued to find adherents. Birdlike wing flapping was very early abandoned as a practical idea except in the minds of a few zealots. The rigid fixed-wing machine seemed to be the answer, but, even more than the airship, it required the development of a powerful, lightweight engine.

It was a Yorkshire baronet, Sir George Cayley, who, in the period 1799–1810, first laid the basis of aerodynamics and, in the opinion of many, became the true inventor of the modern airplane. Between 1804 and 1853 he established the basic configuration of the airplane, both in small and large model gliders, and finally (1852–53) in the first man-carrying glider of history, in which his coachman was successfully flown with locked controls. Cayley built his gliders with the now familiar features of forward main planes, fuselage, adjustable fin and tail plane, rear rudder and rear elevator. He understood and provided for both longitudinal and lateral stability (the latter with dihedral wings), and understood the travel of the centre of pressure. He also realized the need for a lightweight internal combustion engine, the importance of streamlining and the need for a lightweight cycle-wheel type of undercarriage. His suggestion of superposed wings (biplanes, triplanes, etc.) led to their adoption by John Stringfellow in 1868. He realized that cambered wings give better lift, and even that there is an area of low pressure (partial vacuum) over the upper surface that contributes a powerful lifting force. Cayley's theoretical and practical work led directly to many subsequent developments in aviation.

Steam-Powered Airplanes.—The idea of powered flight lay dormant until the historic collaboration of Stringfellow and William Samuel Henson, two inventive Englishmen, in 1840. Together they built a steam-powered model airplane and designed (on paper) an Aerial Steam Carriage which was to have been used on the first regularly organized air transport system in the world, a proposed route from London to India. Although the model failed its final test, illustrations of the Aerial Steam Carriage influenced the whole of Europe.

From 1850 onward a series of inventors, particularly Félix du Temple, Alphonse Pénaud, F. H. Wenham, Victor Tatin, Horatio F. Phillips and Clément Ader, made valuable contributions to heavier-than-air flight. Some made practical progress, especially Ader, who in 1890 claimed to be the first to take off in an airplane under its own power; this was a steam-powered machine which could not, however, make a sustained and controlled flight. Ader made two tests in 1897 with his "Avion III" but (despite his later claims) did not succeed in leaving the ground.

In 1894 Sir Hiram Maxim in England may also have been close to success. He built a huge monoplane and tested it on specially laid railway track. In the course of his experiments he accumulated a great deal of data on air resistance, propulsive efficiency, etc. The machine gave some signs of lifting but was wrecked on its rails and never achieved controlled free flight.

The one thing that all early efforts had in common was the use of a steam power plant. At that time, however, it was impossible to build an efficient, lightweight steam power plant suitable for aircraft propulsion. Such a device might now be possible with modern design techniques, but a steam-driven airplane is considered economically impractical.

Langley's Experiments.—One other man of that period, a scientist of considerable repute, the secretary of the Smithsonian institution in Washington, D.C., almost attained the goal of man-carrying mechanical flight. Samuel Pierpont Langley's story is perhaps one of the most poignant in the long history of aeronautical research.

After many years of experimentation with small models of varying configurations (which he called "Aerodromes"), one of which made a circular flight of ¾ mile in 1896, he attempted to build and fly a full-scale machine. Using a remarkably light (for its time) gasoline engine designed and built by his assistant, Charles Manly (based on an earlier design), he made two attempts to launch his machine from the top of a houseboat in the Potomac river below Washington. On both occasions the launching catapult fouled the machine, causing failure. The machine crashed into the river for the second and last time on Dec. 8, 1903, just nine days before the successful flights by the Wright brothers near Kitty Hawk, N.C. Langley became a butt of ridicule by the nation's newspapers. A few years later (in 1906) he died.

Many years later (in the summer of 1914) Langley's "Aerodrome" was rebuilt and flown in its allegedly original condition from the waters of Lake Keuka, N.Y. Actually, however, a number of major modifications had been made in the structure of the machine, and it was also fitted with an engine much more powerful than the original Manly engine. Whether or not it could have flown given more favourable circumstances in the autumn of 1903 is still a matter of considerable doubt. Nevertheless, Langley remains as one of the great experimenters in aviation's age of exploration. (S. P. J.)

Man-Carrying Gliders.—Because practical, lightweight power plants were not available until almost the end of the 19th century, man's first real steps toward heavier-than-air flight were made in man-carrying gliders. A Breton sea captain, J. M. Le Bris, made the first man-carrying glider in the shape of an albatross around 1856 and a similar machine a few years later, but made no successful flights. By 1865, however, Louis Mouillard had built and attempted to fly a gliding machine in Algiers. His efforts were largely unsuccessful, but the book that he wrote as a result, *L'Empire de l'air*, was an important inspiration for later experimenters.

Although a number of men had made tentative experiments with gliders, it was the German engineer Otto Lilienthal who (during

BY COURTESY OF (RIGHT) SCHWEIZER AIRCRAFT CORP.; PHOTOGRAPH, (LEFT) AUTHENTICATED NEWS INTERNATIONAL

(LEFT) BIPLANE GLIDER, 1895, ONE OF TWO BUILT BY OTTO LILIENTHAL, GERMANY. (RIGHT) MODERN TWO-PASSENGER SAILPLANE

the period 1891–96) became the first to fly and control gliders in the air, and so to lay the groundwork for successful airplane pilotage. After many experiments and the building of a number of monoplane (and two biplane) gliders, Lilienthal succeeded in achieving a limited but successful method of glider flying, in which—after launching himself from a hill—he hung in the machine by his arms and controlled its stability and steering by swinging his torso and legs in any desired direction, thus shifting the centre of gravity. It was the widespread descriptions and photographs of his flying and the tragedy of his death in a gliding accident (1896) that directly inspired the Wrights in America, Percy S. Pilcher in England and many less successful pioneers, and led to the conquest of the air. (*See* GLIDING.)

The Wright Brothers.—Powered airplane flight—effective powered, sustained and controlled flying—was first achieved by the American brothers Wilbur and Orville Wright of Dayton, O. After studying all the literature they could find on flying, especially the American Octave Chanute's classic *Progress in Flying Machines* (published 1894), they experimented with a large kite in 1899 and then went on to construct and fly three biplane gliders (1900–02) near Kitty Hawk, N.C., in which stability and control were at first secured by the use of a front elevator and warping (twisting) of the wings for banking, turning and maintaining lateral stability. Success did not come, however, until they had carried out extensive aerodynamic experiments and later modified their third glider (during their 1902 season), on which they made nearly 1,000 glides. The secret of their mastery of glider flight—which they were determined to achieve before going on to make a powered machine—lay in their adoption not only of the forward elevator and wing-warping but of a vertical rear rudder operated simultaneously with the warping. This arrangement permitted banked turns and ensured proper control laterally and directionally in flight.

After the success of their 1902 efforts the Wrights at once set out to construct their first powered airplane, called "The Flyer" (or, by Orville in his diary, "the machine"); however, they were temporarily stymied by the absence of a suitably light and powerful motor on the market, and the lack of knowledge of the all-important subject of airscrews. Both of these difficulties were overcome by brilliant research and through the design and construction by themselves, with the aid of Charles Taylor, of a 12-h.p. motor which they installed in a machine based on their 1902 glider and fitted with two chain-driven pusher propellers. It had a skid undercarriage which rested on a yoke fitted with modified cycle hubs and took off along a wooden rail under engine power alone. "The Flyer" was deliberately made unstable and had to be continuously controlled in the air. After a single failure at take-off on Dec. 14, the brothers made four flights near Kill Devil hill (south of Kitty Hawk) on Dec. 17, 1903, which were the first powered, sustained and controlled airplane flights in history. The first lasted 12 seconds, the last 59 seconds during which the machine covered 852 ft., which—because it was flying into a stiff breeze—actually amounted to one-half mile through the air. The age of heavier-than-air flight had begun.

III. PERIOD OF TRIAL AND ERROR (1903–14)

Garbled reports of the Wright brothers' flights, together with other extraordinary circumstances, prevented all but a handful of men from realizing that the Wrights had flown, or that they were later succeeding in perfecting the airplane during 1904 and 1905 in a field near Dayton. With their powered "Flyer" No. 3 in 1905 the Wrights achieved the first really practical airplane in history; it could bank, turn, circle, make figures of eight and keep flying easily for one-half hour at a time. In 1904 the brothers had adopted their weight-and-derrick method of accelerated take-off, which they used until 1910. After the 1905 season, beset by business spies and troubles in promoting their invention, the Wrights did not leave the ground until May 1908; however, they built new engines, together with several improved "Flyers," one of which was shipped to France in 1907 and remained there in customs until the following year.

European Progress.—In Europe, meanwhile, interest in aviation was all but dead, although the Austrian Wilhelm Kress and Capt. Ferdinand Ferber of the French army were attempting heavier-than-air flight. The European situation was transformed however, when the Wrights' friend Chanute visited Paris in 1903 and lectured on his own and the Wrights' gliding, showing photographs and giving details of the 1902 machine. A number of Frenchmen, especially Ferber and Robert Esnault-Pelterie, started to build Wright-type gliders; however, as is clear from their statements and actions, they totally misunderstood what Chanute had told them and thus failed to make successful machines. Most important, they did not realize the overriding importance of obtaining control in the air by operating the warping and rudder together. They also failed to comprehend the Wrights' reasons for making their machines unstable, *i.e.*, to make constant control necessary, and were determined to aim at inherent stability, which had been attained earlier by Cayley and by Pénaud. In this pursuit they were aided by a better appreciation of the Australian Lawrence Hargrave's box kite (which had been invented in 1893), the principles of which some Europeans now applied to their designs. In 1905 Gabriel Voisin, in co-operation with Ernest Archdeacon and Louis Blériot, made two biplane float gliders which were towed off the Seine river by a motorboat. Although unsuccessful they established one of the basic configurations of the European biplane, with Wright-type wing structure divided to make a giant box kite, a forward elevator, a box-kite tail unit and no lateral control.

The following year Santos-Dumont, turning from airships, built a *canard*-type (tail-first) biplane with a 50-h.p. motor, box-kite wings and a combined forward elevator and rudder, and succeeded in making a few short flights at Bagatelle (the longest was 722 ft.). Because progress had been so slow these hops were given prizes and Santos-Dumont was officially credited with the first

powered flights in Europe. Also in 1906 Trajan Vuia (in Paris) established the European monoplane tradition with an ingenious but unsuccessful machine which, however, led directly to Blériot's becoming interested in the monoplane type soon afterward.

Dogged by impatience and lack of careful experimentation, the many French pioneers pursued both the monoplane and biplane in a hopelessly confused manner; until Nov. 1907 no European could stay in the air even for a full minute, and only Henri Farman could make an approximate circle by the year's end.

European aviation was stimulated in 1908, when Wilbur Wright went to Europe and first flew in public in August near Le Mans, France. He displayed a mastery of flying which dumbfounded the French. Orville remained in America and started making acceptance flights for the U.S. army near Washington, D.C., in September. These tests were brought to a sudden and tragic suspension when, on Sept. 17, a fractured propeller caused the machine to crash. Orville was injured and his passenger, Lieut. Thomas Selfridge, was killed—the first fatality in powered aviation.

By the end of 1908 Wilbur Wright had made more than 100 flights in Europe, had broken every record and had even made a flight lasting 2 hours and 20 minutes. The chief points he demonstrated were how to control an airplane in the air (especially laterally), and the technique of making and gearing propellers. From that time onward, having absorbed the lessons taught them by Wilbur Wright, the Europeans drove ahead successfully. They combined their ideal of a reasonable amount of inherent stability —to make it easier for the average pilot—with proper lateral control by means of the Wrights' wing-warping, or its European derivation of hinged ailerons (as used to this day); they also abandoned their inefficient primitive propellers in favour of the type pioneered by the Wrights.

By the time of the world's first air meeting in Aug. 1909 at Reims, European aviation had rapidly come of age, and two basic and efficient types of airplane had emerged—the light rotary-engine-powered Henri Farman biplane, which used large ailerons instead of warping, and the monoplane with either ailerons (as on some of Léon Levavasseur's Antoinettes) or the Wrights' wing-warping (used on the other Antoinettes and Blériot's No. XI). It was Blériot himself—after Hubert Latham had crashed into the sea with his "Antoinette IV"—who, on July 25, 1909, flew his frail little No. XI to victory in the competition to fly the English channel. It was this historic flight, from near Calais to Dover, that not only impressed the airplane forcibly on the public mind but also frightened the chancelleries of Europe into realizing that a new vehicle of terrifying potential had suddenly appeared.

U.S. Progress.—American aviation, apart from the Wrights, had come alive in March 1908 with the tentative flight of the first machine ("Red Wing") built by the Aerial Experiment Association. The most important of the association's aircraft was Glenn Curtiss' "June Bug," which in July won the *Scientific American's* prize for the first public flight of more than one kilometre in the United States. Curtiss was soon to become the most outstanding American designer and pilot after the Wrights.

There followed a period of competition for speed and distance flying which saw new records constantly being set. Flying meets were organized in Europe and America, and the pilots and airplane designers became familiar names to the public. The average citizen looked upon the airplane as strictly a device for daredevils. At that time few believed that it would be utilized either as a weapon of war or an instrument of commerce.

Several significant events occurred in the period 1910–11. In Nov. 1910 Eugene Ely, flying a Curtiss biplane, made the first successful take-off from a ship, the U.S.S. "Birmingham." Two months later he succeeded in landing on and taking off from the U.S.S. "Pennsylvania." In 1911 Curtiss won the first Collier trophy for outstanding aviation achievement for flying the first practical float plane (the first successful such craft was flown in 1910 by Henri Fabre of France). (C. H. G.-S.)

1912–14 Developments.—During the two years preceding the outbreak of World War I (1912–14) aircraft development was rapid, but was still fundamentally on a trial-and-error basis. A few wind tunnels had been built—largely in France—but no significant amount of aerodynamic or structural data had been compiled for the use of designers. Each airplane was more or less an invention. The over-all configurations were many and varied. A few significant changes, however, began to be observed. The original timber-and-wire openwork construction, in which pilots sat in exposed positions, had given way to the development of the fuselage to contain power plant, pilot and passengers, and to serve as a connecting structure for the wings, tail and landing gear.

The fact that the air itself offers considerable resistance to the rapid passage of bodies through it began to be recognized. What is now commonly referred to as streamlining began to be studied. The Deperdussin monoplane, which won the Gordon Bennett cup in 1913, embodied many of the elements that appeared in high-performance airplanes of later decades.

Military staffs began, in the few years prior to World War I, to speculate on the possible employment of the airplane in war. But until 1915, when actual aerial combat between opposing pilots began, the airplane was looked upon only as a possible substitute for light cavalry—a means of reconnoitering the positions and intentions of an enemy army in the field. The long-range capabilities of the airplane were early realized. By midsummer of 1914 a German pilot succeeded in keeping an Albatross biplane in the air over Berlin for more than 24 hours. In the United States that year Glenn Curtiss built for Rodman Wanamaker a three-engined flying boat designed to fly the Atlantic. It was tested at Hammondsport, N.Y., but the planned Atlantic crossing was never attempted because of the outbreak of war.

CULVER PICTURES

WRIGHT BROTHERS' "THE FLYER" RISING FROM GROUND AT KILL DEVIL HILL, N.C., DEC. 17, 1903, TO BECOME THE FIRST POWERED AIRPLANE

years of the 1930s the improved capabilities of the airplane were dramatically demonstrated by a number of new record flights. Wiley Post and Harold Gatty made the first fast round-the-world trip in June 1931 in the single-engined Lockheed monoplane "Winnie Mae." They covered 15,474 mi. in 8 days and 16 hours. Two years later, in July 1933, Post flew solo around the world in 7 days and 19 hours. In 1938 Howard Hughes, flying a twin-engined Lockheed, circled the world in 3 days and 19 hours. These records should be contrasted with the U.S. army's round-the-world performance of 1924, mentioned above.

Air Transportation.—During this period air transportation systems covering the land masses of the globe were established. The transportation of people and goods by air proved to be not only technically feasible but economically profitable. The 1930s brought great improvements in economy, efficiency and safety of air transportation over land. Scheduled air transportation linked many European cities before much active development occurred in the United States. In the late 1920s and the early 1930s air transportation in the United States began with the establishment of a few intercity routes (Detroit-Cleveland, New York-Washington, New York-Miami, Chicago-San Francisco) which more or less followed the routes laid down by the U.S. contract airmail services.

Aircraft available to operators at the time included the famous all-metal Ford trimotor and the large and clumsy Boeing 80 and Curtiss Condor biplanes. The airplanes were slow, airways facilities (lights, radio communication and weather-reporting services) were inadequate and unreliable, and airports equipped to handle large volumes of passengers or goods were few and far between. The advent of the Boeing 247 transports in 1933 and the introduction of the Douglas DC series in 1934 changed the whole trend of development. These airplanes embodied the spectacular advances of 1930–31; *i.e.*, all-metal construction, cowled engines and retractable landing gear. They were also large enough to provide comfortable and relatively soundproof accommodations for passengers. They could carry with them enough electronic navigation and communications equipment for reasonably safe operation in all but the worst weather conditions. Most of the earlier types were powered with two engines. As the 1930s came to an end, however, more four-engined types began to appear; they were the prototypes of the equipment which handled the bulk of the long-range military transport requirements of World War II.

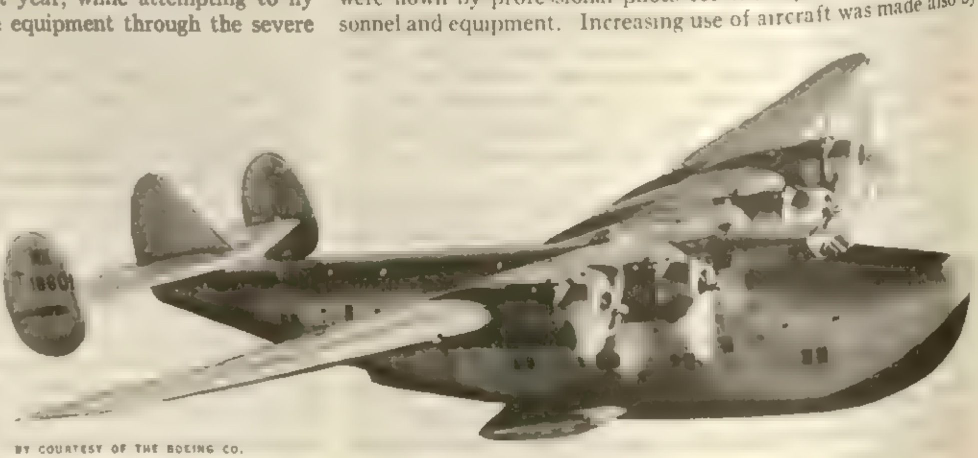
Early in 1934 an event occurred which was to have a profound (and continuing) effect on air transport development in the United States. This was the issuance of an executive order by Pres. Franklin D. Roosevelt canceling out of hand all existing mail contracts on the grounds of alleged fraud and collusion, and ordering the army air corps to take over the operation of the airmail services. Apart from any discussion of the reasons for this sudden and drastic action, the order temporarily disrupted air transportation in the country, and threw an unexpected burden on the military establishment that it was ill prepared to undertake. During the period Feb. 19–June 1 of that year, while attempting to fly mail on schedules with inadequate equipment through the severe weather conditions of the winter and spring, a dozen pilots and many aircraft were lost. This tragic episode had at least two important and long-lasting results: (1) it led to the development of new and adequate legislation for the control and expansion of commercial air transportation in the United States; and (2) by exposing the deficiencies in equipment and personnel training in the U.S. armed services, it initiated an intensive re-examination of requirements for men and matériel which was to prove invaluable when the United States entered World War II.

Toward the end of the 1930s commercial operators were beginning to link up internal air transport systems by regularly scheduled transoceanic flights. By the time the United States entered World War II in Dec. 1941, air transportation, both for military and for commercial purposes, was on a world-wide basis. In such a development it would appear logical that commercial transoceanic operations should be conducted by water-based aircraft; *i.e.*, large flying boats. This was, in fact, the approach made by all countries in first attacking the problem of transatlantic and transpacific operations. Large multiengined flying boats were developed for the purpose. The huge German-built Dornier Do X, having 12 engines, made an experimental round-trip crossing of the Atlantic in 1931–32 but never went into commercial service. The British inaugurated Atlantic services in 1934, beginning with schedules between New York and Bermuda. By the mid-1930s the French were making regular crossings of the South Atlantic in Latécoère flying boats. By 1935 Pan American World Airways System was operating both in the Atlantic and the Pacific, first using Sikorsky S-42's, and later the huge flying clippers built by Glenn Martin and by Boeing. As experience in overseas flying accumulated, however, and particularly after the lessons learned from a vast amount of intercontinental flying during World War II, the concept changed completely. With the increased reliability of aircraft, engines and communication equipment, the advantages of the land-based airplane over the flying boat became so apparent that the latter had disappeared entirely from international commercial services by 1950. (*See* AVIATION, CIVIL.)

Private Flying.—The extent of private ownership and operation of aircraft in the 1930s was much less than had been predicted by the prophets of the post-Lindbergh era. One of the principal reasons for this was the onset of the depression in the early 1930s, which limited the amount of money that manufacturers were willing to spend on development as well as that which potential customers were willing to spend. Nevertheless, a slow increase in private flying took place during the first five years of the decade and, as prosperity returned, private flying accelerated noticeably up to the period of the U.S. entrance into World War II.

Many people took up flying for pleasure and, as the interest increased, a number of new airplane types aimed at the private-owner market became available. Except for training and for purely sport use, a marked trend toward enclosed-cabin types occurred. People wanted to fly but they wanted to fly in comfort. The glamour of the "helmet, boots and breeches" type of pilot dimmed. People wished to travel in the same comfort (and in the same style) as they did in their privately owned automobiles.

The chief deterrents to widespread popular use of airplanes however, were the relatively high costs of equipment and operation and a general inability to navigate and fly safely in any but good weather conditions. Some larger, well-equipped machines capable of all-weather operations were built for a few people who could afford the luxury of professional pilots, but their number was small. Public companies also began to use airplanes, which were flown by professional pilots for the rapid transport of personnel and equipment. Increasing use of aircraft was made also by



BY COURTESY OF THE BOEING CO.

BOEING CLIPPER, INTRODUCED IN 1938, ONE OF THE FIRST AIRPLANES CAPABLE OF OPERATING COMMERCIALLY ON TRANSOCEANIC FLIGHTS

oil companies and public utilities for inspecting long pipelines and power lines. In some places, particularly the midwestern United States, Canada and Australia, farmers began to fly their own airplanes to inspect their properties and herds, or to spray insecticides. Altogether, however, the manufacture and sale of aircraft for such purposes engaged only a small part of the industry.

Gliding.—On the purely sport-flying side, gliding and soaring in motorless aircraft occupied a good deal of attention and came to a high degree of development both in Europe and America during the 1930s. This activity had its roots in Germany where, during the late 1920s, and under the provisions of the Versailles treaty of 1919, severe restrictions had been put on the development of powered airplane flight. Although soaring and gliding had not been unknown in the United States prior to that time (*e.g.*, Orville Wright soared for almost 10 minutes in a biplane glider in 1911 at Kitty Hawk), there was a considerable upsurge of interest in motorless flying in the early 1930s. The machines in use, however, were far removed from the clumsy gliders of Chanute and the Wright brothers. Some of these beautifully designed and highly refined soaring machines represented tremendously high levels of aerodynamic efficiency. The activity also led to extensive and detailed research in weather phenomena, which was of great subsequent benefit to all forms of flying.

Helicopters.—Before turning to the advances of the World War II period (1939–45) three other developments of the late 1920s and the 1930s—two in the heavier-than-air field, the other in the lighter-than-air category—should be mentioned.

An early idea for a means of flying was to use a system of overhead horizontally-rotating propeller blades. This is the helicopter (*q.v.*). Leonardo da Vinci was for many years credited with originating the idea but it is now known that the Chinese made helicopter toys before da Vinci's time. A number of later inventors had the same idea, including Sir George Cayley in England, Paul Cornu and the Breguet brothers in France and Thomas Edison in the United States. To all these people the idea seemed good, but as was the case with all other experimenters prior to 1900, they lacked an engine that could develop enough power to produce sufficient vertical thrust to raise its own weight (plus some useful load) from the ground. Actually, Cornu made the first, though primitive, free vertical ascent in a helicopter in 1907. During those years no one approached close enough to a solution to realize that there were also many difficult and complicated problems of control to be solved before a vertical rising machine, or helicopter, could become a practical device.

It is of interest to note that the brilliant designer of large airplanes and flying boats, Igor Sikorsky, designed and built a helicopter in Russia in 1909. His machine actually lifted its own weight from the ground but had no reserve left for pilot or passengers. Much later Sikorsky returned to the study of helicopters and produced in 1940 the prototype of a long line of successful machines under his own name, and touched off the development of many others by other designers.

During the 1920s Henry Berliner and George de Bothezat in America, Étienne Oehmichen in France, Raoul Pescara in Spain and Corradino d'Ascanio in Italy built awkward and clumsy machines which did succeed in getting a few feet off the ground with pilot aboard, but it remained for the Germans in the last half of the 1930s to produce the first real helicopter development. In 1937 the Focke-Achgelis helicopter was demonstrated in Berlin. Hanna Rasche made a number of successful cross-country flights, and in Feb. 1939 Ewald Rohlfs set an altitude record of 11,700 ft.

Once the basic principles had been established the development was rapid on both sides of the Atlantic, and a considerable use of these vertical-lift machines was made during World War II. It was not until the war in Korea (1950–53), however, that they really proved their value as military vehicles.

Autogiros.—Another type of aircraft, which resembled the helicopter very closely in outward appearance but operated on substantially different principles, also appeared in the early 1920s, and went through a considerable development cycle prior to 1940. This was the Autogiro, or the so-called gyroplane. The Autogiro differs from the helicopter in that the rotor system is not power-driven during flight but is in effect a set of rotating wings, rotation being derived from aerodynamic action of the air (autorotation). Power for forward motion is provided by a conventional propeller. Autogiros are incapable of true vertical flight but they can take off and land at relatively slow speeds with little take-off or landing roll, a combination which permits safe operation in and out of extremely small areas. The basic principle of the Autogiro, *i.e.*, autorotation, was evolved first by the Spanish inventor Juan de la Cierva. Between 1920 and 1923 he developed a number of machines with rotating wing systems; however, none was successful until, in 1923, he hit upon the idea of articulating the rotor blades at the rotor hubs, thereby making possible satisfactory aerodynamic control of the machine. During the following ten years a number of commercial and military Autogiro designs appeared in Britain, France and the United States. Most of these were open-cockpit two-seaters, but toward the end of the period several three- and four-seat enclosed-cabin machines were offered for sale. Toward the end of the 1930s the inherent limitations of the type, however, slowed down interest in their development in most countries, and the revival of interest in the helicopter virtually eliminated the Autogiro from further consideration by most manufacturers. The gyroplane idea was revived again in the late 1950s when Igor Bensen put on the market a "build-it-yourself" design for a single-place, low-powered gyroplane for sport use. An un-powered version also became available for use as a manned "kite" towed by automobile or by motorboat.

Airships.—The major development in lighter-than-air craft in the period between World Wars I and II was in the field of large, rigid airships—ships of the type developed by Graf von Zeppelin prior to World War I. Some development of nonrigid airship types (blimps) continued after 1918 but tapered off very rapidly during the following 15 years. The major military interest was evidenced by naval staffs, who found several uses for such machines for offshore patrol or coastal defense purposes. Considerable technical developments took place in the use of materials and in aerodynamic design. In the United States helium was made mandatory as a lifting gas in place of inflammable hydrogen. Few nonrigid airships were produced, however, until World War II when more than 150 saw service in various theatres, principally as antisubmarine weapons.

The so-called "semirigid" airship, a compromise between the blimp and the Zeppelin types, attracted a few experimental designers in the 1902–12 decade. The Italians revived the concept toward the end of World War I. The U.S. army purchased the Italian-built "Roma" in 1921, but it was wrecked and burned at Langley field, Va., shortly after delivery. An all-U.S. design, the RS-1, was purchased in 1925, flown experimentally for about two years, and then abandoned. In 1926–27, the Italians built two large semirigids, "Norge" and "Italia," both of which were used successfully in polar exploration. During the following few years the Russians were said to have built several airships of this type, but since that time little attention has been given to this category of aircraft.

During World War I the Germans achieved considerable success in long-range bombing operations with the Zeppelin-type rigid airship. On two occasions during 1917 German Zeppelins made flights of almost 100 hours' duration. Such performances led many people to believe that large airships would play a prominent part in aviation development during subsequent periods. A number of Zeppelins were distributed to the Allied nations as a part of postwar reparations. In this way the U.S. navy acquired the LZ-126 (ZR-3), renamed the "Los Angeles," which was flown to the United States in Oct. 1924.

In Great Britain construction of two large airships had been undertaken during the last year of the war. In July 1919 one of them, the R-34, took off from Scotland, made a transatlantic round trip and returned to England. Inspired by this performance the U.S. navy ordered a British-built airship, the R-38, which, however, was destroyed on its trial flight in England in Aug. 1921. This ended U.S. interest in British-built airships. However, in the United Kingdom design and construction continued, and culmi-

nated eight years later in the launching of the R-100 and the R-101, ships which were designed for commercial use across the Atlantic ocean and to the far east. The R-100 made one transatlantic round trip in 1930, but after the R-101 was destroyed over France in Oct. 1930, work on rigid airships was abandoned by the British.

During this period the Germans carried the development of the rigid airship to its highest point. Under the Versailles treaty airship work was prohibited until 1926, at which time the Zeppelin company began the construction of a purely commercial airship, the LZ-127, which became famous as the "Graf Zeppelin." Under its commander, Hugo Eckener, this ship made many flights to all parts of the world during the following years. Based on its record, the Germans undertook a much more ambitious project, construction of the LZ-129, christened the "Hindenburg." Ten round trips across the Atlantic were made by the "Hindenburg" in 1936, but on the first trip of 1937 the airship, while making a landing at the Lakehurst (N.J.) naval air station, caught fire, and was completely destroyed in minutes. Like all other German airships, it had used hydrogen as a lifting gas.

The U.S. navy undertook the design and construction of a rigid airship, the "Shenandoah." It was commissioned in Oct. 1923, but was destroyed in a storm over Ohio in Sept. 1925. Shortly thereafter the German-built "Los Angeles" was delivered, and remained in service with the U.S. navy without accident until it was finally decommissioned in June 1932. Meanwhile, two larger airships were designed and constructed in the United States, the U.S.S. "Akron" and the U.S.S. "Macon." The "Akron" was commissioned in Oct. 1931, but was destroyed less than two years later in a storm off the New Jersey coast. The "Macon" went into service in June 1933, but was wrecked off the California coast in Feb. 1935. These ships had many novel design features, such as internally mounted engines, water recovery systems, and a capability of housing, launching and retrieving small fighter airplanes. After the unfortunate experiences with the "Akron" and the "Macon" interest in the construction of rigid airships virtually disappeared in the United States and elsewhere.

V. PERIOD OF ACCELERATED DEVELOPMENT (1940–)

All the research and development, the speculation as to utility and utilization, and the theorizing as to the role of aircraft as military weapons came suddenly into focus with the outbreak of World War II in Europe in Sept. 1939. Military requirements on a scale never before contemplated accelerated development toward new levels of performance and utilization. The limitations which confronted aircraft designers were imposed less by technical feasibility than by economic considerations, human operating skills and human physical endurance.

For the most part, the fighter and bomber pilots of all the combatant nations of World War II flew aircraft which were no more than improvements upon designs which had been evolved in the late 1930s. Everything that research scientists had learned from wind tunnels and in structural test laboratories was incorporated in the production models in an effort to outfly and to outfight the opposition. Aircraft in all categories were markedly better in 1944 than they had been in 1939, but progress had been evolutionary, not revolutionary.

Military Jet Aircraft.—A really revolutionary concept, one that was to provide a breakthrough in aircraft design and operation, was, however, in the offing. In the mid-1930s, working secretly under strict security measures, German, Italian and British designers were experimenting with a new form of aircraft propulsion, the gas-turbine jet. (For a description and details of this type of engine, *see* AIRCRAFT PROPULSION: *Jet Engines*.) An Englishman, Frank Whittle, took out his first patents for a jet-propelled aircraft in 1930. Two German students, Hans von Ohain and Max Hahn, applied for their first patents in 1935.

The first flight of a jet aircraft occurred on Aug. 27, 1939, with the German Heinkel He 178. Almost two years later, in May 1941, a Gloster aircraft powered with a Whittle engine was flown in England. The first jet flight in the United States took place on Oct. 1, 1942, when a Bell XP-59A, powered by two I-16 General Electric turbojet engines (based on the Whittle design), was flown from Muroc Dry lake (later Edwards air force base), Calif. By the end of the war in 1945 almost 1,300 Messerschmitt Me 262 twin-jet fighters had been built, and Britain had the Gloster F-9-40 Meteor in full production. Both these aircraft became operational too late to have much effect on the outcome of the war but their performance proved conclusively that a new era in design had arrived.

Air Power in World War II.—Great efforts were made by all combatants of World War II to secure control of the air in every theatre of operation and to destroy opposing economic capabilities by mass bombing raids against centres of industry and population (*see* AIR WARFARE). Germany tried to bring England to terms by air bombardment during the summer and early fall of 1940, an effort which was nullified by the heroic defense put up by British fighters, aided by radar. The tables were turned in 1943–45 when the combined air power of Great Britain and the United States subjected German industrial centres to round-the-clock bombings, thus helping pave the way for the Allied victory.

Meanwhile, carrier-borne naval aircraft played a vital role in the drive by U.S. amphibious forces across the Pacific toward Japan. Finally, U.S. air force bombers, operating from the Marianas, destroyed Japanese industrial centres, culminating in the atomic bombing of Hiroshima and Nagasaki in early Aug. 1945. As an indication of the production effort behind such large-scale operations, it may be noted that between Dec. 1942 and Jan. 1944 the United States produced (in round numbers) 29,000 bombers, 39,000 fighters, 7,000 transports, 20,000 trainers and almost 6,000 miscellaneous types. In 1944 the U.S. purchased 96,318 airplanes.

German V-1s and V-2s.—One other radical new development which was to have far-reaching effects on military strategy occurred during the last year of World War II. In a desperate, last-ditch effort to break through British defenses and cripple British industry the Germans developed two new types of aerial weapons—the V-1 flying bomb (also called robot bomb and buzz bomb) and the V-2 ballistic rocket.

The V-1 was, in effect, an unmanned airplane, powered by a simple pulse-jet engine and carrying a 2,000-lb. warhead in its nose. Launched from prepared sites along the French channel coasts, these machines flew on

BY COURTESY OF U.S. NAVY

preset courses with London as a target. Initially the effort was successful and considerable damage was done in London, but the British defenses soon learned to cope with this type of attack, and the effort was abandoned in the early fall of 1944. The rocket attacks by the V-2s began shortly thereafter. These large rockets (about 45 ft. long, weighing initially 13 tons and carrying a 2,000-lb. explosive warhead) were launched from sites in the Netherlands, rose about 60 mi. into the air and plunged vertically into the London target area 200 mi. away. They did considerable damage in London, and were stopped only when the ground forces overran and captured the assembly points and the launching sites in early March 1945.

(LEFT) SIKORSKY S-64 SKYCRANE CARRYING REMOVABLE CARGO AND PASSENGER VAN; (RIGHT) BENSEN GYROCOPTER

Although these German weapons failed to accomplish their intended purpose they laid a pattern which, in the next decade, led to the development of huge, intercontinental ballistic missiles (ICBM's) and eventually provided the technical knowledge from which the capability of putting satellites into orbit was derived. (*See* ROCKETS AND GUIDED MISSILES; SPACE EXPLORATION.)

Postwar Disruption of Aviation Industry.—The termination of the war in 1945 and the subsequent cancellation of orders for thousands of military aircraft brought severe disruption to the aviation industry. Huge factories were shut down, the flow of materials in pipelines ceased and thousands of workers were released. Several years went by before growing orders for new airline equipment could relieve the situation. Huge fleets of mothballed military aircraft were put into storage. Although the purchase of new military aircraft by governments practically ceased, manufacturers continued to develop new designs built around the jet engine.

Air Power in the Korean and Vietnam Wars.—When the war in Korea broke out in June 1950 a few of the newer types were available. In the air over Korea, U.S. Sabrejets engaged Soviet-built MIG-15s, marking the first time in history that jet aircraft met in aerial combat. During this period (1950–53) jets also came to be used more and more for low-level attacks on ground targets when slower conventional aircraft (mostly of World War II vintage) proved too vulnerable to antiaircraft fire.

It was during the Korean operations that the helicopter first came into common use as a military machine. Large numbers of these rotary-wing aircraft played a major role in rescuing downed pilots, directing artillery fire and transporting personnel to and from front-line positions. Many hundreds of wounded were transported directly from front lines to base hospitals.

After the Korean War there was a great upsurge in the use of helicopters both by the armed forces and by civil transport companies. They were extensively used by the U.S. in the war in Vietnam during the mid-1960s. On the civil side, regular passenger-carrying shuttle services were offered from downtown (sometimes rooftop) areas to outlying airports in many U.S. and European cities. Speed, range and carrying capacity were tremendously improved.

Postwar Air Transportation.—Meanwhile, considerable progress had been made in the postwar development of commercial aircraft to implement the growing network of domestic and international airlines. Thousands of twin- and four-engined transport types had been used throughout the world during World War II, and the experience gained thereby was invaluable in the first postwar decade in developing passenger and cargo-carrying systems. In the first three postwar years domestic route mileage in the United States multiplied more than three and one-half times, and passenger traffic increased at the rate of 20%–25% per year. Airmail tonnages climbed, and the shipment of freight by air increased rapidly.

The transition from the improved postwar propeller-driven transport types to the high-speed jet-powered transport began with the introduction into service of the de Havilland Comet by the British Overseas Airways corporation in 1952. Britain had taken the lead in jet transport development in the early postwar period and had also pioneered the development of turbine propeller-driven types, the Vickers Viscount being the best-known of these turboprops. For a time Britain was definitely in the lead with these two transport aircraft. Comets were on regularly scheduled service to South Africa, India and the far east, and the Viscounts were being sold in all countries, including the United States.

Within two years' time, however, a series of dramatic accidents caused the grounding and withdrawal from service of the Comets. Almost five years elapsed before the modified Comet IV came back into commercial operation. During the late 1950s the French-built Caravelle (with twin jet engines mounted in the tail of the fuselage) found considerable use on many European and U.S. airlines.

Meanwhile, U.S. designers had turned their attention to jet transport design, and early in 1960 the Boeing 707 jet transport came into commercial operation in the United States. During the following two years the Boeing 707, the Douglas DC-8 and the Convair 880 were produced in large quantities and took over practically all long-range U.S. domestic and overseas routes and were also widely used by many foreign airline operators.

During the 1962–64 period most jet aircraft for long-range operation were corrected to the so-called "fanjet" engines for greater power and economy. Several new intermediate range transports appeared during the 1960s, notably the Boeing 720, the Boeing 727, and the DC-9. The Boeing 727 was characterized by the installation of three jet engines, all mounted in the tail of the fuselage.

During the 1950s and 1960s the Soviets, also starting from scratch, made great strides in their development of jet-powered and turboprop commercial air-transport equipment. Beginning with the post-World War II development of twin-engined propeller-driven machines (similar in size and performance to the U.S. DC-3s), they produced in little over a decade a large fleet of pure jet and turboprop transports of a size and capability equal to any in the world. Typical are the TU-104 pure jet and the huge multiple turboprop transport, the TU-114.

During the 1960s a great deal of attention was focused on the possibilities of supersonic transport. A design study (and some construction) was undertaken jointly by the U.K. and France in an attempt to develop a Mach 2 (two times the speed of sound, or about 1,500 m.p.h.) machine. In the U.S. the Federal Avia-

tion agency and a group of manufacturers began evaluating designs for a Mach 3 airplane, but an actual flight date remained several years in the future. Many basic problems (heat-resistant materials, high-energy fuels, economic feasibility, "sonic booms," etc.) had to be solved before commercial Mach 3 flight could become a reality.

Air Lifts.—Beginning in the late 1940s the capability of air lifting large numbers of people and great quantities of goods into almost every area of the world had a profound effect upon the political, economic and sociological trends of the times. Such operations included the Berlin air lift (1948–49), in which large quantities of food and fuel were flown into the blockaded city, and Operation "Magic Carpet" (1952), in which thousands of Muslim pilgrims, stranded in Lebanon by a transport shortage, were flown to Jidda, Saudi Arabia, enabling them to reach nearby Mecca in time for an important Islamic festival. The dropping of food and other supplies into areas isolated by fires, floods or other natural disasters has often prevented major economic losses and has saved hundreds of human lives. This was again dramatically demonstrated by the mass evacuation of white refugees from the Congo during the uprisings in that area in the fall of 1964. And finally, the swift and economical transportation available to all parts of the globe has allowed an interchange of people and of ideas which has helped create a better basis of understanding among nationalities.

International Regulation of Airlines.—The rapidly expanding network of international airlines brought a need for international regulation of traffic and of equipment. As a result of an international convention called by Pres. Franklin D. Roosevelt in Chicago in Sept. 1944, two permanent international bodies were formed—the International Civil Aviation organization (ICAO) and the International Air Transport association (IATA). The history of these organizations, and an account of their operations, is covered in AIR LAW and AVIATION, CIVIL.

Military Aircraft.—During the 1950s the military aircraft of all the major powers underwent a revolutionary change in appearance and performance of an even more radical nature than occurred in the early 1930s. After the U.S.-built experimental airplane X-1 demonstrated in Oct. 1947 that flight beyond the so-called sonic barrier is feasible, fighter aircraft with supersonic capabilities became standard equipment. In design they tended to become very large and complicated, and, as a corollary, very expensive. Wings tended to become smaller and smaller, and the swept-wing or delta configurations were generally adopted. The ever increasing demand for power to achieve high-speed flight resulted in the rapid development of larger and larger turbojet power plants with thrust capabilities many times in excess of that of the original Whittle engine.

Few new fighter planes were designed in the 1960s. Improvement in armament and performance, however, was continuous in all countries. A number of research aircraft of unconventional configuration appeared in the United Kingdom, including several direct-lift supersonic fighters (*e.g.*, the Hawker Siddeley P.1127). In the U.S. the inventory included developed versions of the Ling Temco Vought Crusader, the Douglas Skyhawk and Skyraider, the Convair Delta Dart, the Grumman Intruder, the Lockheed Starfighter, the McDonnell Phantom and Voodoo, the North American Vigilante, the Northrop Talon and the Republic Thunderchief. A new development was a variable-sweep winged, all-service fighter, the F-111 (TFX) developed for the air force and navy by General Dynamics and Grumman.

Bomber types also underwent radical revisions. The Boeing B-29 Superfortress, the type that bombed Japan and dropped the first atomic bombs there, was also flown in the Korean War. By 1949, however, the Convair B-36D, with six conventional and four jet engines, was in service with the U.S. strategic air command, joined in the early 1950s by the six-engined, swept-wing, Boeing B-47 jet.

At the same time the prototypes of Britain's "V" series bombers were already flying. These were the Avro Vulcan, the Handley Page Victor and the Vickers Valiant, all large long-range machines powered by four to six jet engines. In the mid-1950s an even larger

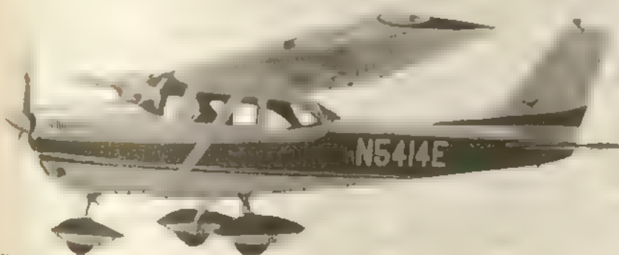
jet bomber, the Boeing B-52, went into service with the strategic air command. With it was developed the Boeing KC-135 tanker for in-flight refueling of bombers. The KC-135 tanker utilized the design from which the Boeing 707 jet transport was derived. A delta-winged 4-jet supersonic bomber, the B-58 built by Convair, was also used by the U.S. air force in considerable numbers. In Dec. 1957 a contract was let by the U.S. air force to North American Aviation for the development of a Mach 3 bomber (B-70), of which three prototypes were to be built. The first of these large planes (approximately 550,000 lb. weight at take-off, 170 ft. long, powered by six turbojet engines) was test-flown in the autumn of 1964. The program was officially abandoned, however, because of the improved United States intercontinental missile capability.

Postwar Private Flying.—Again, as in the post-Lindbergh period (1927–33), aviation enthusiasts predicted a great development of private flying for the post-World War II decade. "An airplane in every garage" had been forecast, with thousands of people flying on business and for pleasure. Estimates of as many as 300,000 privately owned machines in use in the United States within five years of the end of World War II were made by many responsible people. Such demand was confidently expected to replace the cancellation of military orders.

Unfortunately these predictions did not materialize. Pilots trained during the war years soon found that they could not afford to own and operate their own machines. Moreover, the majority of airports were not available for large-scale private flying. Private flyers found that they could operate only in near-perfect weather and in the vicinity of their home airports unless they installed an expensive array of communications and navigational equipment, which few could afford.

As a result, the ownership of airplanes by private citizens virtually disappeared in most countries. In flying clubs, open-cockpit "sports" airplanes were in fairly wide use but under the economic conditions of the 1960s few persons outside the United States could afford to own their own machines for personal use.

In the United States the decade from the mid-1950s to the mid-1960s witnessed a great expansion in the use of non-airline aircraft for business executive travel. Many large corporations with



BY COURTESY OF CESSNA AIRCRAFT CO.

CESSNA SKYHAWK, FOUR-PASSENGER AIRPLANE FOR PERSONAL OR BUSINESS TRAVEL

plants and offices spread over the entire country maintained fleets of their own aircraft. Some of these aircraft were originally used for short-haul airline work, but a number of fast and efficient machines—both jet and turboprop—were designed specifically for this type of service and were in use in large numbers.

Aviation Research; Unsolved Problems.—Despite the fact that public attention was usually focused on putting man into space, there were still many unsolved problems involved in navigating safely within the boundaries of earth's atmosphere. Government budgeting for aeronautical development was at a relatively low level in the 1960s, but remained substantial.

By the mid-1950s speeds were well into the supersonic range. In 1960 the North American X-15 experimental rocket-powered airplane had already exceeded Mach 3 and on Nov. 9, 1961, it attained a speed of more than 4,000 m.p.h. Although designed primarily for shallow penetrations of outer space and for the collection of data on controlled re-entry into earth's atmosphere, the X-15 also provided data on high-speed flight through the air.

The problem of combining vertical take-off and landing (VTOL), or short take-off and landing (STOL), with high-speed horizontal flight engaged the attention of researchers and designers in the late 1950s and 1960s. Helicopters can rise vertically but their top speed is far below desirable limits. The development of a successful VTOL/STOL airplane would go a long way toward the

BY COURTESY OF U.S. ARMY AVIATION MATERIEL LABORATORIES (AVLABS) FORT EUSTIS, VA.

XC-142 VTOL/STOL AIRCRAFT. WINGS TILT TO HORIZONTAL POSITION AFTER TAKEOFF

solution of the airport problem. Such vehicles could pick up their loads in small areas (possibly on roofs) near population centres, rise vertically (or at least very steeply) and proceed at high speed to their destinations, where the process would be reversed. Costly and time-consuming transfers to ground vehicles, as well as long trips between airports and industrial centres, would be eliminated. By the late 1960s aircraft with STOL and VTOL capabilities were being flight tested.

Another area where active research is needed and is being intensified is in the control of air traffic in the vicinity of airports. With the rapidly increasing number of high-speed jet aircraft approaching and leaving terminals, positive separation in flight as well as absolute control of their movements in the air and on the ground is essential for safe operation (*see* AIRPORT). This control becomes more important and more difficult in periods of bad weather. The danger of collision of two jet airliners carrying several hundred passengers over a thickly populated area must be avoided at all cost. On Dec. 16, 1960, the worst aviation disaster in history occurred when a jet airliner collided with a propeller-driven airliner over New York city, resulting in the deaths of 134 persons.

Such problems, difficult as they may seem, will be resolved in time. Probably relatively few human beings will participate in space exploration or indulge in space travel. Many millions will, however, use the atmosphere as a medium for travel. It is important, therefore, for man to explore every means at his disposal to attain complete mastery of the ocean of air which surrounds him.

AVIATION FUEL: *see* AIRCRAFT PROPULSION.

AVIATION INSURANCE. The rapid development of the aviation industry between World Wars I and II led to a demand for insurance for both planes and passengers. As new government agencies were created to exercise controls over pilots and flights and to establish safety standards, the development of aviation insurance underwriting was greatly assisted. By the end of World War II aircraft hull and aircraft liability insurance underwriters had developed insurance policies patterned after other forms of property and liability insurance. However, the relative inexperi-

ence of aviation insurance underwriters, coupled with the almost phenomenal growth in air traffic with its attendant hazards, resulted in inadequate insurance rates and substantial underwriting losses. By 1960 some stability had been achieved, but aviation insurance was still a relatively new form of insurance that dealt with an industry subject to changing hazards and catastrophic accidents.

UNITED STATES

In addition to aviation personal accident insurance, the principal types of aviation insurance coverage are aircraft hull, covering loss or damage to the plane; aircraft liability (similar to automobile liability insurance), covering the insured's legal liability for bodily injury or property damage; admitted aircraft liability, under which voluntary settlements with passengers may be made without recourse to the legal liability of the insured, thereby releasing the insured from legal liability; cargo liability, covering the airline's liability for loss or damage to baggage and cargo (physical damage to air-borne cargo is usually not considered aviation insurance but it is written by inland marine departments of fire insurance companies or by inland marine insurers); hangarkeeper's liability, covering the hangarkeeper for his liability for damage to aircraft hulls entrusted to him for repair or storage (similar to automobile garage keeper's liability); airmeet and airport liability, covering on-premises liability (similar to on-premises liability coverage under an Owners', Landlords' and Tenants' policy commonly used by other businesses); products liability, covering the hull manufacturer, those responsible for aircraft repair and maintenance and salesmen; medical payments, which, like automobile medical payments coverage, will pay up to policy limits for necessary medical expenses for injuries, without regard to fault liability. The aircraft and aviation industry also uses other forms of insurance to cover real estate, inventories, automobiles, workmen's compensation and employer's liability.

Certain users of airplanes, such as those who charter or rent them and who operate from a given airport, may obtain many of the above types of coverage in one special package policy. The owners of light planes weighing less than 2,000 lb. fully loaded have available a special comprehensive light plane policy to cover the hull.

Owners of cargo shipped by air may wish to insure their interests through air cargo coverage because the airlines are not required to insure the cargo they transport, and airline liabilities may not be identical. The movement of air cargo, it should be noted, is not limited to air travel but includes surface carriers such as trucks and railroads. The Railway Express Agency, Inc., for example, provides the same service for air express cargo as for railway express cargo. Not all cargo shipments are domestic but may be shipped in international commerce. The liability of air carriers may not be identical for domestic shipments and international shipments, which may be subject to the terms of the Warsaw convention (1929). (*See* AIR LAW.) Furthermore, cargo may be shipped through consolidators or forwarders via scheduled or nonscheduled airlines. Scheduled airlines are common carriers, and their liability may be different from that of a nonscheduled airline, which may not be a common carrier. Cargo owners may, for the above reasons, wish to insure consistent with the nature of their risks of loss in relation to probable recoveries under the insurance or liability of air carriers, scheduled or nonscheduled, in domestic or international commerce.

Aviation insurance rates are no more standardized than are the aviation insurance policies. Although certain classes of risks may lend themselves to so-called average rates, these rates are no more than guides subject to adjustments based upon the underwriter's judgment of a particular risk within the class. Underwriters consider such factors as the experience of the airline and its pilots; the condition, age and depreciated current market value of the equipment; the financial condition of the airline and its relative competitive position; and the airline's safety record. These and many other factors will determine the insurance rate. In many forms of coverage the total premium for the year will be determined from the insured's own report of the total exposure during the contract term. As is partially the case in automobile insurance, aircraft are often classified for rate purposes according to use; *i.e.*, commercial, limited commercial and private business and pleasure.

Jet and turboprop transports typify the need for a dynamic insurance company management responsive to the needs of modern business or industry. Judgment is essential especially when rates and coverages must be promulgated for new types of hazards, many of which are catastrophic. New jet and turboprop planes with high value per aircraft, large seating capacity and high speed practically double the exposure per unit over the straight piston-type aircraft. Besides the air-borne risks, limited fleets mean a limited number of ground or surface passenger and maintenance installations with concentrated values in aircraft hulls and relatively costly maintenance equipment and facilities. This results in further lack of spread of risk along with a high concentration of values exposed to catastrophic losses. (J. W. CE.)

GREAT BRITAIN

In Great Britain, as in the United States, many of the earlier troubles of aviation insurance were overcome with the rapid growth of civil aviation after World War II, but new problems arose with each succeeding year. From the very beginning of civil aviation in Great Britain the resources of the established insurance market were made available to the aircraft industry. From this close association with the fortunes of the aviation industry for more than 40 years, aviation insurance, once regarded as a mere sideline for the marine underwriter, progressed to a broadly based independent section of the British market.

The aviation insurance market in London consists of two specialist companies formed by groups of influential British insurance companies, a number of Lloyd's underwriting syndicates formed expressly for the purpose of underwriting aviation risks, and other Lloyd's syndicates. There are also a few insurance companies that underwrite aviation risks mainly as an adjunct to their marine departments.

Nothing in the nature of tariff rating exists and, apart from the use of standard policy forms, underwriters have virtually complete freedom. There are, however, market agreements on matters such as war risks. There are two associations of underwriters, one representing Lloyd's and the other representing the company market. These two bodies frequently co-operate on matters of market interest, or where the interest of clients is concerned. They have done much valuable work in conjunction with government departments concerned with national and international legislation affecting carriage by air. As a result, the liability of the carrier on internal carriage in the United Kingdom is, with certain modifications, brought into line with that applicable to international carriage. Internationally, Great Britain subscribes to the Warsaw convention but has not ratified the Rome convention.

AVIATION MEDICINE, the science of preventing or treating illnesses and injuries that occur to aviators and those who work in the manufacture, maintenance and operation of aircraft and missiles. (For a description of space medicine *see* SPACE EXPLORATION: *Space Science: Life Sciences.*)

The practitioners of aviation medicine must be intimately acquainted with the science of flight, the characteristics of aircraft and the nature of the tumultuous atmosphere in which they are operated.

The first scientist to go aloft for the purpose of making medical observations was John Jeffries, a U.S. physician who ballooned from England to France in 1785. Since that time aviation medicine has continued to be international in nature, with all the leading European and North American countries contributing major advances in research, practice and teaching.

French physiologist Paul Bert (*q.v.*) is generally regarded as the "father" of modern aviation medicine. In his *La Pression Barométrique*, published in 1878, he described his pioneer in-

vestigations of the physiological effects of air pressure, both above and below normal. The work was translated into English in 1943 and used extensively during World War II.

In the early 1960s all major aircraft companies had departments of "human engineering," a field of knowledge comprising one of the basic sciences of aviation medicine. In these departments, physicians, psychologists, engineers and other scientists worked at such tasks as designing the arrangement of instruments for easy comprehension; the size, shape and position of controls, seats, and lights; the insulation, ventilation and pressurization of passenger and crew compartments; and the sanitation of food and waste facilities. Each aircraft company also had a medical department to provide pre-employment and periodic medical examinations of aviators and ground personnel and to treat occupational diseases and accidents of employees.

On or near each airport there usually was at least one aviation medicine specialist who examined aviators in accordance with standards established by a national regulatory authority and also exercised surveillance over personal protective equipment, ventilation, cleanliness, noise levels and toxic hazards of employees at the airport. In addition, each large airport had on its staff a chief medical officer who supervised the sanitation of the port in accordance with health standards established by national and international authorities.

A primary function of aviation medicine has been to examine and determine the fitness of aviators and of candidates for flight training. It is universally recognized that the safety of a flight may be threatened if the pilot or other members of the flight crew possess inadequate sight, hearing, strength, co-ordination, intelligence, courage, equilibrium, emotional stability or lack ability to retain consciousness. Specialists in aviation medicine have sought to ensure that persons in whom these inadequacies are found or suspected are not permitted to operate aircraft. The aviation medicine specialist is equally concerned with ensuring that the health of crew members is not impaired during flight. For this reason, aviation medicine specialists constantly study the hours crews spend per month at the controls, their diet, their peace of mind and the physical and mental stresses to which they are subjected by low air and oxygen pressure, noise, vibration, air turbulence, poor visibility and heavy responsibility.

An aeromedical task almost as old as aviation is that of flying the patient to the doctor. Early air ambulances were developed in the United States and Europe in 1910, and the French army transported wounded soldiers by air in 1915. During World War II more than 1,000,000 military patients were transported by air. The number of civilian patients carried by air to and from many of the world's great centres of medical care had increased by the early 1960s to hundreds monthly.

The armed services of most nations were served in the early 1960s by aviation medicine specialists, commonly called flight surgeons. These doctors were assigned to aircraft carriers, operational squadrons, groups and wings, air staff organizations, hospitals that cared for aviators, and to aircraft and missile research design and test organizations where they performed the same general functions as their civilian colleagues. Most specialists in aviation medicine have been trained in military schools of this specialty. Such schools are or have been maintained by the armed forces of the United States, Canada, Great Britain, Germany, the U.S.S.R., Argentina, Brazil and France. In the 15 years following the end of World War II specialty training programs in aviation medicine were established at four universities in the United States.

Specialists in aviation medicine, both medical and nonmedical scientists, have organized a number of professional societies. The foremost of these in the early 1960s was the International Aero-Space Medical association, which was founded in 1929 by Louis H. Bauer and a group of examiners appointed by the Civil Aeronautics administration.

In the United States, aviation medicine was recognized by the medical profession as a specialty in 1953, and in the first seven years after recognition approximately 900 doctors were certified in this specialty by the American Board of Preventive Medicine. The specialist in aviation medicine in the late 1950s acquired the responsibility for the health and safety of rocket launch crews and future spacemen. These men and women operate in an extremely hazardous environment where the dangers of poisoning, temperature, pressure and anxiety become extreme. In missile support operations the aviation medicine specialist must combine clinical knowledge and psychological understanding with a detailed knowledge of fuel toxicities, firing systems and ground and range safety to prevent human failures that can cause missile failures.

AVICENNA (ABU-ALI AL-HUSAIN IBN ABDULLAH IBN SINA) (980–1037), Persian philosopher and physician, very influential in both the Islamic world and the Latin middle ages, was born in a village near Bukhara in Turkistan. His father had joined the Ismaili movement, and although Avicenna did not follow in his steps, the preference that he shows for the Plotinian element in the late Greek synthesis of Platonism and Aristotelianism may have some root in early acquaintance with the Ismailis. At the age of 18 he could consider himself an accomplished physician and had acquired all the immense philosophical knowledge displayed in his large philosophical encyclopaedias and in his numerous small treatises. After the collapse of the Samanid empire in 999 he decided to leave Bukhara, and the later decades of his life are marked by some vicissitudes. About 1020 he was vizier in Hamadan. The last 14 years of his life were spent in the company of 'Ala ad-Daula, the ruler of Isfahan, whom he followed on all his journeys and on all his military ventures. He died in Hamadan in 1037. His extant writings, some of which are in his native Persian though most are in Arabic, include an autobiography (completed by an intimate pupil).

Philosophical Works.—Avicenna's philosophical doctrines are described in the article ARABIC PHILOSOPHY. Unlike Averroës, Avicenna did not write commentaries. The best-known of his large philosophical encyclopaedias is *Ash-Shifa* ("The Recovery"; *i.e.*, of the soul from error), called *Sufficientia* in Latin versions. In this he treats logic (nine books), the natural sciences, including psychology (eight books), the *quadrivium* (four books) and metaphysics, but there is no real exposition of ethics or of politics. The logic, the psychology and the physics were translated into Latin in the 12th century; and by the middle of the 13th century versions of the section on metaphysics, of the summary of the *De Caelo*, of the meteorology and of the zoology had been added. Editions of this partial translation were printed in 1495 and 1508.

A résumé of *Ash-Shifa*, called *An-Najat* ("The Salvation") became rather popular and was printed as an appendix to *Al-Qanun* in 1593. Both *Ash-Shifa* and *An-Najat*, as well as *Al-Qanun*, were finished in Isfahan, where Avicenna also composed the last great work of his to have come down to us in its entirety, *Isharat wa-Tanbihat* ("Demonstrations and Affirmations"). This covers the whole of philosophy and may represent its author's most mature thought.

The important work in which Avicenna distinguished his "oriental" philosophy from the "occidental" philosophy of the Christian philosophers of Baghdad, the *Kitab al-Insaf* ("The Book of Equitable Judgment"), was lost when his belongings were scattered during the pillage of Isfahan in 1034; only three unconnected sections have survived. His "Oriental Philosophy" itself seems to be irretrievably lost (with the exception of a few pages) and may never have been completed by him. Some smaller theological or mystical treatises and the "Poem of the Soul" also deserve mention.

Medical Works.—Avicenna's most famous medical work is *Al-Qanun fi'l-Tibb* ("The Canon of Medicine"), a systematic encyclopaedia based for the most part on the achievements of Greek physicians of the Roman imperial age and on other Arabic works and, to a lesser extent, on his own experience (his own clinical notes were lost during his journeys).

This work not only became extremely popular in the Islamic

world, but also was studied in European universities for centuries, first in a 12th-century translation by Gerard of Cremona (printed 15 times before 1500), then in a new translation by Andrea Alpago of Belluno (1527 and later editions). It was also the second text ever to be printed in Arabic (1593).

AVIGNON, a city of southeastern France, capital of the *département* of Vaucluse, lies on the Rhône river where it leaves its narrow valley for the wide delta plain, 66 mi. N.W. of Marseilles by road. Pop. (1962) 64,581.

The city is built on the left (east) bank of the Rhône where rising ground on both sides of the river gives defensible sites (Avignon on the east and Villeneuve-lès-Avignon on the west). The Île de la Barthelasse is in the river between them. In the winter the town suffers severely from the mistral winds. A few miles below Avignon the Durance reaches the Rhône from the east, and the city is a nodal point for the roads from this valley and the east side of the Rhône generally. Similarly, Villeneuve is a focus of roads on the west. The division of the river somewhat reduced the difficulty of crossing, and so helped to give the site its importance, but the power of the Rhône was so great that a bridge could not be built in antiquity even by the Romans. In 1178–88, however, St. Bénézet built one which was broken down and repaired at various times and was finally abandoned in 1680. The part of the bridge supported by the four arches nearest Avignon still stands and has on it the original Romanesque chapel (with 16th-century portions above) dedicated, as is usual on such sites, to St. Nicholas. The true version of the famous song "Sur le pont d'Avignon" should read "Sous le pont . . ." as the dancing took place in the shade of the bridge on the Île de la Barthelasse. Lower down the river a suspension bridge and a modern bridge cross the Rhône.

W. SUSCHITZKY

FORTRESS-PALACE OF THE POPES, AVIGNON, 14TH CENTURY

Avignon is still almost surrounded by its 14th-century ramparts, built by the popes, with machicolated battlements, towers and gateways. Outside the walls is a ring of boulevards. The town is dominated by the palace of the popes, which stands on top of a steep hill, and the cathedral close to it. The latter, a Romanesque building of the 12th century, contains the tombs of Popes Benedict XII and John XXII, the former a masterpiece of 14th-century Gothic work. The cathedral is more or less dwarfed by the fortress palace of the popes, begun in 1316 by John XXII in the Gothic style and continued until 1370. It now belongs to the city. The palace is surrounded by high walls, flanked with eight towers, inside which are also the Clementine chapel (over the Hall of Great Audience) and two chapels with 14th-century Italian frescoes. Among the Gothic churches of the town are St. Pierre (14th and 16th centuries) with a graceful façade and richly carved doors and St. Agricol (14th and 18th centuries) with a façade dating from 1489. The Calvet museum, in a 15th–18th-century house, contains paintings, furniture, wrought iron, Greek and Roman remains, etc., as well as a fine library. There is a sculpture museum in the 17th-century Jesuit church. An annual arts festival (in July) takes place when plays are staged in the palace of the popes.

Avignon is on the main line from Paris and Lyons to Marseilles and there is an airport at Caumont, five miles to the southeast. John Althen, a Persian, introduced in 1765 the culture of the madder plant which long formed the staple, and is still an important branch, of local trade. There are flour mills, and oil and leather works. Soap and chemicals are manufactured, and wine, teasels and almonds are traded, while the city is well known for its sarcenet and other fabrics.

Avenio, as it was known in classical times, was a town of the Gallic tribe of Cavares, but under the Romans it enjoyed only a secondary importance in Gallia Narbonensis. Severely harassed by barbarians and Saracens, it later belonged successively to the kings of Burgundy and of Arles and to the counts of Provence, Toulouse and Forcalquier. At the end of the 12th century it became a republic, but in 1226 it was dismantled by Louis VIII as punishment for its support of the Albigenses, and in 1251 was forced to submit to the counts of Toulouse and Provence. Pope Clement V made it his residence, and from 1309–77 it was the papal seat. In 1348 the city was sold by Joan, countess of Provence, to Clement VI. After Gregory XI had migrated to Rome two antipopes, Clement VII and Benedict XIII, resided at Avignon, from which the latter fled in 1408. Avignon was a bishopric in the 3rd century and became an archbishopric in 1475. The town and the surrounding territory of Comtat-Venaissin (*q.v.*) remained in possession of the popes, who governed by means of legates (*see* Papacy), until annexation during the French Revolution by the national assembly in 1791, when conflicts between the adherents of the papacy and the republicans led to much bloodshed.

In World War II Avignon was in German hands from Nov. 1942 to Aug. 1944.

ÁVILA (from the Latin *Abula, Avela,* but perhaps also from the Punic *Abyla*), a province (area 3,107 sq.mi.) and its capital city situated in Old Castile (*q.v.*) in central Spain. Pop. (1960): province 238,372; town 26,807 (mun.). The city (officially Ávila de los Caballeros) lies 54 mi. W. of Madrid on the Adaja river. It is surrounded by 8,202 ft. of walls in polygonal form, with 82 forts, 2,500 merlons and 9 gates, built during the 12th century when the city was finally reconquered from the Moors. The whole of ancient Ávila is contained within the walls; the

modern part is outside. The apse of the Romanesque cathedral forms part of the walls, giving it the appearance of a fortress. The city is a noted tourist centre. St. Teresa was a native of the town and a convent and church mark the site of her alleged birthplace. The fact of Ávila's having been a *ciudad real* (Queen Isabella was born there) is reflected in the number of palaces and noble houses. Many of these buildings are in the plateresque (Renaissance) style, with magnificent doorways, as in the house of Gil González de Ávila. Particularly noteworthy are the work of the goldsmith Juan de Arfe y Villafane (16th century), preserved in the cathedral, and the paintings of Pedro de Berruguete.

Ávila province extends to the Tiétar; it advances north for some distance across the plateau of Old Castile. On the level ground in the north, the centre of which is Arévalo, agriculture predominates, but the soils are poor, resting on outwash from the central Sierras. For the rest, Ávila is a province of sierras, mainly granite, rising steplike from the plateau to the Sierra de Gredos, and separated from each other by longitudinal valleys which are, in some cases, dried-up lake bottoms along lines of structural weakness. Of these the best known are the Barco de Ávila and the Valle de Amblés; the latter lies at the eastern end of an important structural line, giving a natural route from Plasencia to Ávila. The headwaters of the Alberche and Tiétar rivers, flowing to the Tagus, and of the Tormes and Adaja, flowing to the Duero, occupy these longitudinal valleys. The province is crossed by two main roads, from Madrid to La Coruña and from Villacastin to Vigo, and also by the railway lines from Madrid to Irún and from Ávila to Salamanca. The most important towns are Candeleda, Arenas de San Pedro and Arévalo. There is little industrial development and the economy is mainly agricultural. The raising of stock, especially of the Merino sheep (of which the purest breeds surviving in Spain are found in the central Sierras), is the principal occupation; the forests, mostly pine, are still important in places. The pastures and forests formed the basis of the life of the medieval communities, subdivided into *sexmos*, between which the area of the present province was divided. Wheat, with and without irrigation, is increasing its acreage. Rye, barley, oats, maize and tobacco are also grown. Modern methods are widely adopted; production of cereals exceeds consumption, and a surplus is exported to other parts of Spain. The vine flourishes only in such areas as the Tiétar and Alberche valleys, which produce wines of some repute; olive cultivation is confined to a few sheltered localities (Arenas de San Pedro, Cebreros) with very high yield. Estates are generally large; there is often a shortage of labour, and harvesters are brought in from Galicia. The sierras formerly abounded in game, but the diminution of the ibex of the Sierra de Gredos led to the creation in 1905 of an ibex sanctuary. There are also graphite quarries. (M. B. F.)

AVISON, CHARLES (1709–1770), English composer, organist and writer on musical aesthetics, was born at Newcastle upon Tyne, and baptized there in Feb. 1709. Little is known of his early life: he may have gone to Italy, and was perhaps a pupil of Francesco Geminiani, who was certainly a friend of his later.

He was appointed organist at St. John's, Newcastle, in July 1736 and at St. Nicholas' in October. He taught harpsichord, violin and flute, and conducted the newly founded subscription concerts. He composed and published many concertos for stringed instruments, sonatas for harpsichord and strings, etc. His *Essay on Musical Expression* (1752) excited comment and evoked a pamphlet, published anonymously, from William Hayes, professor of music at Oxford (1753), to which Avison replied with an enlarged edition of the *Essay*. A third edition appeared in 1770. Avison lived all his life at Newcastle, refusing appointments at York, Dublin, Edinburgh and London. He was visited by Geminiani in 1760; among his many friends was the composer John Garth of Durham, whom he assisted in editing Marcello's *Psalms*. He died at Newcastle, May 10, 1770.

As a composer, Avison was a representative of the last phase of the late baroque "ancient" style. It is difficult to enumerate his many concertos, for, like Geminiani, he was continually revising his earlier works. Although his music lacks the vigour of Handel or Vivaldi, it has its own wistful beauty. His trenchancy as a critic is shown in the famous *Essay* and in his explanatory or didactic prefaces to his own and his friends' works, which also throw considerable light on 18th-century methods of performance.

See M. Kingdon-Ward, "Charles Avison," in *The Musical Times* (Sept. 1951); A. Milner, "Charles Avison," in *The Musical Times* (Jan.–Feb. 1954). (Cs. Ch.)

AVITUS (Eparchius Avitus) (d. A.D. 456), Western Roman emperor from 455 to 456, was born of a distinguished Gallic family and was father-in-law of Sidonius Apollinaris. He acquired much influence with the Visigoths settled at Toulouse, and in 451 persuaded their king, Theodoric I, to join the Roman general Aetius in repelling Attila and the Huns from Gaul. He was appointed *magister utriusque militiae* ("master of both services") by the emperor Petronius Maximus, and when Maximus fell, the Goths proclaimed him emperor at Toulouse. At Arles, accompanied by a Gothic force, he was recognized as emperor by the Gallo-Romans. He then proceeded to Rome and entered upon his consulship on Jan. 1, 456, when Sidonius recited a panegyric on him. On Oct. 17, 456, he was forced by Ricimer (*q.v.*) to abdicate and to become bishop of Placentia. He died soon after. (E. A. T.)

AVOCADO, the fruit of *Persea americana* of the family Lauraceae, a tree native to the mainland of the western hemisphere from Mexico south to the Andean regions of Colombia and perhaps Venezuela. The common name is a sound substitute for the Aztec *ahuacatl*, originating probably in Jamaica, where also the name alligator pear arose as a sound substitute, plus reference to the pearlike shape and appearance of many varieties.

The avocado first became known to Europeans through a description published in 1519 by Martin Fernández de Enciso in his *Suma de Geografia*. Enciso had seen the fruit near Santa Marta, Colom., as he coasted along those shores with one of the first Spanish expeditions to the mainland. In 1526 Gonzalo Fernandez de Oviedo described it in greater detail. Garcilaso de la Vega tells how it was carried from Ecuador to the warm valleys near Cusco by the Inca Tupac Yupanqui, shortly before the Spanish conquest. The common name in Peru and southward is *palta*. In most Spanish-speaking countries, *aguacate*, an adaptation of *ahuacatl*, is used; in Brazil this becomes *abacate*.

The tree may be tall or spreading, with entire leaves commonly elliptic to obovate in form and 4 to 12 in. in length. The flowers, which are borne in dense racemes, are small, greenish, devoid of petals, with six perianth-lobes, nine stamens arranged in three series, and a one-celled ovary. The fruit is exceedingly variable in shape, size and colour; some of the Mexican varieties are no larger than hens' eggs, while those of other races may attain three or four pounds in weight. The form varies from round to pear-shaped with a long slender neck, the colour from green to dark purple. The single large seed, with two cotyledons, is round to conical. Between it and the outer skin, which is sometimes no thicker than that of an apple, sometimes coarse and woody in texture, is the greenish or yellowish flesh, of buttery consistency and rich nutty flavour, containing in some varieties as much as 25% of oil, and eaten most commonly in salads, whence the name "salad fruit" which has been used to emphasize the peculiar characteristics of the avocado.

BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

AVOCADO (PERSEA AMERICANA): (LEFT) WHOLE FRUIT; (RIGHT) CROSS SECTION OF FRUIT SHOWING SEED

Though it was widely cultivated in tropical America before the Spanish conquest—in the form of individual seedling trees in dooryards—the avocado did not begin to receive serious horticultural attention until about 1900. At that time George B. Cellon

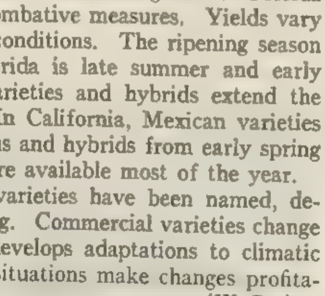
and other horticulturists in Florida found that the production of grafted trees is not difficult, thus making possible the perpetuation of superior seedlings and the establishment of orchards that would produce fruit of uniform size, appearance and quality. After that time flourishing industries developed in Florida and California, in South Africa and on a somewhat smaller scale in Chile, Brazil, Hawaii, Australia and some of the islands of the South Pacific. Cuba produces quantities sufficient for its own needs and for export to the United States. Mexico, where avocados are extremely popular, produces large quantities annually; commercial plantings have been made in Israel, and there are numerous trees in other countries around the Mediterranean.

Horticulturally, avocados are commonly divided into three races, recognized as early as 1653 by Fray Bernabe Cobo. These are the Mexican, the West Indian and the Guatemalan. The first-named, considered by some botanists to be a distinct species, *Persea drymifolia,* is native to Mexico, and is characterized by the aniselike odour of the leaves, and by small (3 to 8 oz.) thin-skinned fruits of rich flavour and excellent quality. This is the hardiest race and therefore of value in regions too cold for the others. The Guatemalan race is native to the highlands of Central America; is slightly less frost-resistant than the Mexican; and produces fruits of medium to large size (8 to 32 oz.), characterized by thick woody skins and a ripening season different from that of the others. The West Indian race (it would more properly be termed South American) is the most tropical in character, and its cultivation in the United States is limited to southern Florida. Its fruits are frequently of large size and excellent quality. Natural crossing has taken place between these three races, resulting in numerous varieties of mixed character, some of them important commercially.

Avocados can be grown on a wide variety of soils, from the light sandy ones of central Florida to the heavy clays of southern California, but drainage must be perfect. A rich sandy loam or clay loam is perhaps best. Propagation of commercial sorts is by grafting or budding, though seedlings are more commonly grown in the tropics and are to be seen as dooryard trees in California and Florida. In the former state, the Mexican race is used as a rootstock; in Florida, the West Indian is more popular. Avocados will not tolerate severe drought, hence irrigation is used in many regions, especially those where there is lack of rainfall during the period when the trees are flowering and setting fruit. Cultural attention varies in different regions; little pruning is required. Various insect pests and fungous diseases attack the groves in Florida and California, some requiring combative measures. Yields vary with variety and environmental conditions. The ripening season of West Indian varieties in Florida is late summer and early autumn, but the Guatemalan varieties and hybrids extend the period to February or March. In California, Mexican varieties ripen in late autumn, Guatemalans and hybrids from early spring to late summer. Fruit is therefore available most of the year.

Several hundred pomological varieties have been named, described and propagated by grafting. Commercial varieties change from time to time; experience develops adaptations to climatic and soil conditions; and market situations make changes profitable.
(W. Po.)

AVOCET (AVOSET), a wading bird about 18 in. long related to the sandpipers and placed in the family Recurvirostridae together with the stilts and the ibisbill. There are four species: one in North America; one in Europe, Asia and Africa; one in Australia; and one in South America. All have slender, upcurved bills, webbed feet and plumage that is largely white with much black in the wings.



ALLAN D. CRUICKSHANK FROM NATIONAL AUDUBON SOCIETY

AVOCET (RECURVIROSTRA AMERICANA)

The avocet lives in shallow shores of ponds and even muddy seacoasts. Sometimes the birds gather into large flocks. They usually feed by swinging the bill from side to side through the water to capture small insects and crustaceans. They frequently wade while feeding, although they can swim.

The avocet builds a simple nest on the ground near water; four boldly marked eggs are laid, and the downy young are active soon after hatching.
(A. L. RD.)

AVOGADRO, AMEDEO, CONTE DI QUAREGNA E CERETTO (1776–1856), Italian physicist, was the enunciator of the hypothesis known later as Avogadro's law (*see* AVOGADRO'S CONSTANT), one of the basic concepts of modern chemistry. He was born at Turin on Aug. 9, 1776, and died there on July 9, 1856. For many years he was professor of higher physics at Turin university. His hypothesis (1811), which made an important distinction between atoms and molecules, was not accepted generally until after Stanislao Cannizzaro in 1858 had constructed a logical system of chemistry based on it.

For the historical position of Avogadro's law, *see* CHEMISTRY: *Studies of Chemical Composition (1800–1900)*; *see* also ATOM: *Avogadro's Hypothesis.*

AVOGADRO'S CONSTANT is the number of molecules in one mole or gram-molecular weight of a substance, both defined as the molecular weight in grams. The constant is invariably the same, whatever the substance, its value being $(6.02486 \pm 0.00016) \times 10^{23}$ as determined by R. T. Birge in 1941 and is denoted by the letter N. The concept, based on Avogadro's law, was enunciated by Amedeo Avogadro in 1811. The previous value assigned to the constant, approximately 6.06×10^{23}, was proved to be incorrect by X-ray diffraction from crystals.

Avogadro's law states that equal volumes of different gases at the same temperature and pressure contain the same number of molecules; *i.e.,* the volume of a mole or gram-molecular weight is constant for all gases. This is correct only for perfect gases but is approximately true for real gases.

See ATOM: *Gases and the Molecular Hypothesis.*

AVOIRDUPOIS WEIGHT (from the French *avoir de pois,* "goods of weight"), the name of a system of weights used in Great Britain and the United States for all commodities except precious metals, gems and medicines. The foundation of the system is the grain. There are 252.458 gr. in one cubic inch of water. There are 27.3 gr. in one dram; 437.5 gr. (or 16 drams) equals one ounce; 7,000 gr. (16 oz.) equals one pound. Fourteen pounds equals one stone; two stones equals one quarter. Above this point the U.S. and British avoirdupois systems differ. In the United States 100 lb. equals one hundredweight; 2,000 lb. equals one ton. In Great Britain eight stones (112 lb.) equals one hundredweight; 20 cwt. (2,240 lb.) equals one ton. In the United States the British ton is referred to as a gross ton or long ton.

See WEIGHTS AND MEASURES: *The U.S. Customary System; The British Imperial System.*

AVON, (ROBERT) ANTHONY EDEN, EARL OF (1897–), British statesman, was prime minister from April 6, 1955, to Jan. 9, 1957. His distinction rests upon his skill in diplomacy and his ability, for the greater part of his public career, to express the middle opinion of the British people, irrespective of party, on foreign affairs. Yet, during his political life, he was twice at the heart of national storms. The Suez conflict in 1956 was one occasion. His resignation from the office of foreign secretary in Neville Chamberlain's government (Feb. 20, 1938) was the other.

From his birth everything seemed to be in Eden's favour. He was born on June 12, 1897, at Windlestone hall, Durham, of an old county family. He was sent to Eton and, on leaving school, went into the army during World War I. He was an infantry officer in France by 1915, became a brigade major at the age of 20 and was awarded the military cross. After the war he went to Christ Church, Oxford, where he obtained a first-class honours degree in oriental languages. He entered parliament in 1923 as Conservative member for Warwick and Leamington (the constituency which he represented until his resignation in 1957). He quickly made a mark in the house of commons. He was young, handsome and devoted to the task of building a new world from which war should be eliminated. Eden was appointed parliamentary private sec-

retary to the foreign secretary, Sir Austen Chamberlain, in 1926; he held the post until 1929. He became undersecretary of state for foreign affairs in 1931, was promoted lord privy seal (with special responsibility for foreign affairs) in 1934 and was made minister for League of Nations affairs in June 1935. In Dec. 1935 he was appointed foreign secretary in succession to Sir Samuel Hoare—a move which was taken by critics of Hoare's policy of appeasement toward Italy (expressed in the Hoare-Laval pact which envisioned the cession to Italy of some Ethiopian territory) to mean that a firmer League policy would be followed and that resistance to Hitler and Mussolini would be stiffened.

© KARSH, OTTAWA

LORD AVON

However, British diplomacy was hindered by the relative weakness of the country. The government was reluctant to convince public opinion, still shocked by the casualties of World War I, that rapid and powerful rearmament was necessary. Consequently, it was not possible for Eden as foreign secretary always to take as strong a line in foreign affairs as his supporters wished. By the beginning of 1938 Hitler's aggressiveness was frightening the whole of Europe and had begun to alarm Pres. Franklin D. Roosevelt in the United States. The president sent a message to Prime Minister Neville Chamberlain in Jan. 1938 asking for the British government's views on the value of a proposal to hold a conference to discuss the international situation. Eden was vacationing in France when the president's message arrived and when Chamberlain replied. Chamberlain suggested the deferment of such a conference until British approaches to Italy had been completed. Eden returned to London on Jan. 15 and protested that Chamberlain not only had missed a precious opportunity to strengthen Anglo-U.S. co-operation at a time of mounting danger but had done so to placate Italy when its conduct forfeited the right to any gesture of friendship from Great Britain. Eden therefore resigned on Feb. 20, 1938. Sir Winston Churchill, writing of this event in *The Gathering Storm,* said it had taken from the government the man who "seemed to me at this moment to embody the life-hope of the British nation."

On the outbreak of World War II in Sept. 1939 Eden re-entered the Chamberlain government as dominions secretary. When Churchill became prime minister in May 1940 Eden's place was assured; he served for a short time as secretary of state for war, but from Dec. 1940 until the Churchill government fell in 1945 he was, once more, foreign secretary. Churchill advised King George VI that if he (Churchill) became a war casualty Eden should be his successor.

When the Conservatives returned to office in Oct. 1951 Eden again became foreign secretary. During his final term at the foreign office he added to his reputation for diplomatic skill. He assisted in the settlement of the Iranian oil dispute, in resolving the quarrel between Italy and Yugoslavia over Trieste and in ending the war in Indochina. The Indochina problem was especially difficult, and Eden's strenuous efforts during the Geneva conference in 1954 contributed greatly to the final settlement. After peace was made, he was instrumental in establishing the Southeast Asia Treaty organization. In 1954 Eden's personal intervention secured the establishment of a western European defense system and averted a European crisis. The French assembly rejected the plans for a European Defense Community in August 1954. Eden immediately made a tour of the European capitals and then arranged a nine-power conference in London. His announcement at the conference that Great Britain would maintain its present forces on the continent unless a majority of the Brussels treaty powers agreed to their withdrawal went far toward removing French grounds for objection, and the western European defense agreements were signed in October. He was created a knight of the Garter.

Eden had married in Aug. 1952 Clarissa Churchill, a niece of Sir Winston (an earlier marriage having been dissolved). He became seriously ill in 1953, underwent three operations and spent several months in convalescence, but he appeared to be quite well when he returned to duty. He succeeded Churchill as prime minister in April 1955 and led his party successfully through a general election a few weeks later. He continued his efforts to relax international tension by welcoming to Great Britain in April 1956 Nikita Khrushchev and Marshal N. A. Bulganin, the leading representatives of the U.S.S.R.

Within two years Eden had resigned the premiership and his seat in parliament. He had never regained full health after the illness of 1953 and he was unable to withstand the strain and shock caused by the Suez conflict (*see* EGYPT: *History*). Eden's direct concern with Suez began when, as foreign secretary, he had negotiated the agreement with Egypt (Oct. 1954) that led to the withdrawal of British troops from the Suez canal zone. He answered Conservative critics of this withdrawal by expressing a hope that it would permanently improve Anglo-Egyptian relations. He was angered, therefore, when Col. Gamal Abd-al-Nasser, head of the Egyptian government, announced (July 26, 1956) the nationalization of the Suez Canal company, in which the British government was a principal shareholder.

This action set in motion the chain of events which led to the Anglo-French attack on Egypt. International discussions in the United Nations and elsewhere had stopped immediate military action, but the French government began to work closely with the Israeli government, which had been moved, by constant Arab provocation, to try its military strength against Egypt. Eden himself denied (Dec. 20, 1956) that he had had foreknowledge of Israel's attack on Egypt, but added that the risk of such an attack had been known and that consequently "discussions" with the French had taken place.

The development of the Suez policy was accompanied by a series of storms in the British house of commons. Eden was accused of flouting the United Nations, alienating the United States, offending the commonwealth, running the risk of a third world war and, by some of his own supporters, of bungling the military operations. His defense was that Anglo-French action had stopped the fighting between Israel and Egypt and had at last forced the United Nations to take effective action. Eden's show of aggressiveness toward Egypt was more widely supported in Great Britain than the Labour and Liberal parties had expected. The main complaint of Eden's supporters was that he had not completed the intention, announced in the ultimatum of Oct. 30, 1956, to occupy "temporarily" the key positions of Port Said, Ismailia and Suez.

Eden's health collapsed under the strain of these events. It was stated on Nov. 21, 1956, that on medical advice he would spend three weeks in Jamaica. He returned to London on Dec. 14 and defended his Suez policy once more in the house of commons on Dec. 20, but on Jan. 9, 1957, he resigned because of recurring ill-health. He published his memoirs in three volumes: *Facing the Dictators* (1962), *The Reckoning* (1965), and *Full Circle* (1960); the last volume (but the first to be published) covered the years 1951–57. A volume of essays, *Toward Peace in Indochina,* was published in 1966. He was created earl of Avon in July 1961. *See* also ENGLISH HISTORY. (J. F. B.)

AVON, the name of several rivers in the British Isles and in parts of Europe. In this form the word is Celtic and itself means river or water. It has been suggested that another proper name may have been associated with it, as is the case in Welsh where it appears as *afon.* The same root appears in place names throughout Celtic areas—*Evan, Aune, Anne, Ive,* etc., in Britain; *Aff, Avon, Aune* in France; *Aven* in Breton; *abhann* in Irish; and *aon* in Manx. Related forms are the Sanskrit *ap,* "water," and the Latin *aqua* and *amnis.* In England the following are the principal rivers of this name.

The East or Hampshire Avon rises on the north side of the Vale of Pewsey in Wiltshire and flows across the vale through

Pewsey to Upavon. Length excluding minor sinuosities, 48 mi.; total fall 500 ft.; drainage area 1,132 sq.mi. From Upavon the river follows a very nearly north-south course across the eastern part of Salisbury plain to Amesbury and Salisbury and the western part of the Hampshire basin by Fordingbridge and Ringwood, to enter the English channel through the nearly landlocked Christchurch harbour. From Upavon to Salisbury the river meanders considerably among meadowland in a narrow valley with many villages and much evidence of early settlement. Below Salisbury the valley is wider with several watercourses in places, but there are few settlements near the river itself. The main tributaries are the Bourne on the east bank and the Wylye on the west at Salisbury, and the Stour which enters just above Christchurch harbour. The river is not navigable but was probably greatly used in prehistoric times giving access to the important early settlement area of Salisbury plain. It has valuable salmon fisheries and a good deal of coarse fish.

The Lower or Bristol Avon and its upper tributaries drain the dip-slope of the south Cotswolds toward the vale of west Wiltshire in which it passes through Chippenham and Melksham. Length of the river, excluding minor sinuosities, about 75 mi.; total fall just over 500 ft.; drainage area 891 sq.mi. At Bradford-on-Avon the river enters a narrow gorgelike valley as it swings abruptly northwestward through the Cotswolds past Bath and on to Bristol. In Bristol the Avon has a straight channel excavated in the early 19th century when the original meandering course was converted into the city docks which are reached by seagoing vessels. Below Bristol the river traverses a section of Carboniferous Limestone through the well-wooded and picturesque Clifton gorge, spanned by the famous suspension bridge. At Avonmouth, the ocean port of Bristol, the Avon enters the Severn estuary whose large tidal range it shares. The most important tributaries are the Somerset Frome which joins the Avon on its south bank just below Bradford-on-Avon and the Bristol Frome which joins it in the middle of Bristol. At Bath the river is linked by a ladder of seven locks with the Kennet and Avon canal. (Fk. Wr.)

The Upper Avon, also called the Warwickshire, and sometimes the "Shakespeare" Avon from its associations with Stratford, is an eastern tributary of the Severn. It rises near Naseby in Northamptonshire, and, with a course of 96 mi., joins the Severn immediately below Tewkesbury in Gloucestershire. After flowing southwest to Rugby it runs west and southwest to Warwick, receiving the Leam on the east. Continuing southwest it goes past Evesham to Tewkesbury. The valley is broad, and especially after Warwick, through the Vale of Evesham, the scenery is very beautiful, the rich valley being flanked by the bold Cotswold hills on the south and by the wooded Arden district on the north. Famous beauty spots include Warwick castle, Stratford and Evesham. The river is locked, and formerly carried some trade up to Evesham, 28 mi. from Tewkesbury; the locks from Tewkesbury upward to Stratford (45 mi.) are decayed, but there are many reaches suitable for pleasure boats. Total fall of river, about 500 ft.; from Rugby about 230 ft.; and from Warwick 120 ft. Coarse fish abound.

Among other streams of this name in Great Britain are one from Dartmoor to the English channel; one in south Wales with its mouth at Aberavon in Glamorgan; and, in Scotland, tributaries of the Clyde, Spey and Forth.

AVRANCHES, a town and port of Manche *département*, northwestern France, stands on a 341-ft.-high hill above the estuary of the Sée, overlooking Mont-Saint-Michel, 89 mi. S. by road of Cherbourg. Pop. (1962) 8,828. The town, largely destroyed in World War II, was rebuilt, and retains some of its old houses. The town hall library contains illustrated manuscripts of the 8th and 15th centuries brought from the abbey at Mont-Saint-Michel, and incunabula from the abbey of Lucerne near Granville. Avranches is in the centre of a cattle- and sheep-rearing region; salmon and trout are fished in the Sée. The chief manufactures are knitted goods and copperware. Important under the Romans and in the duchy of Normandy, Avranches endured its worst siege in 1591. In 1639 it was the centre of the peasants' *va-nu-pieds* revolt against the salt tax. From 511 to 1790 Avranches was a bishop's see, when the cathedral was pulled down as unsafe. The site is now open, one stone remaining to mark where Henry II of England received absolution for the murder of Thomas Becket. In July 1944 U.S. forces under Gen. George S. Patton broke out of the Normandy "pocket" there. (R. T. T.)

AVUNCULATE. A special relationship between a maternal uncle (Lat., *avunculus*) and his sisters' children, particularly his nephews, prevails in many societies, notably those characterized in the present or past by matrilineal descent. It typically involves, on the part of the uncle, a measure of authority over his nephews coupled with specific responsibilities in their upbringing, initiation and marriage. The nephew, in turn, often enjoys special rights against his uncle's property and frequently takes precedence over the latter's own children in regard to inheritance. In many matrilineal societies the nephew leaves his parental home in boyhood or adolescence and goes to live with or near his maternal uncle in an arrangement known as "avunculocal residence." This and matrilocal residence, *i.e.*, with the wife and her relatives, represent alternative modes of achieving a local organization based on matrilineal descent. The core of the local group, whether an extended family or a localized clan, consists in the former case of the men of a matrilineal lineage; in the latter case, of its women. Not infrequently a nephew has a preferential right or obligation to marry a daughter of his maternal uncle—a form of cross-cousin marriage. When this occurs, residence may be at the same time avunculocal and matrilocal, with the men of the local group belonging to one lineage, their wives to another. Although most elaborately developed in matrilineal societies with avunculocal residence, the avunculate also is prominent in most of those with matrilocal or patrilocal residence. It likewise occurs in a moderate number of patrilineal societies. In many such cases it may be derived from an earlier matrilineal system but this is by no means always its origin, for even in an old and integrated patrilineal system special roles may be assigned to a maternal uncle as the senior male member of the mother's patrilineal kin group. Preferential cross-cousin marriage between the father's sister's son and the mother's brother's daughter is, in fact, more characteristic of patrilineal than of matrilineal societies. Within the system of bilateral descent—figuring through both male and female lines—that prevails in slightly more than one third of the world's known cultures, including those of western Europe, the avunculate and associated usages have either failed to develop or have almost disappeared. (*See* also Matriliny.)

(G. P. Mk.)

AVVAKUM PETROVICH (1620/21–1682), archpriest leader of the Old Believers (*q.v.*) and the most original and modern of Russian 17th-century writers, was born in Grigorovo near Nizhni Novgorod. From his boyhood his stormy personality and his religious fervour brought him into conflict with those around him. In 1652 he went to Moscow and quickly joined in the struggle against the reforms of the patriarch Nikon (*q.v.*). In 1653 he was banished to Tobolsk, Siberia, and was then sent farther east to the Lena and the Amur, where he suffered severe injustice. In 1663 he was recalled, but the difficult journey took him three years. Although Nikon by then had fallen, Avvakum, who vigorously took up the cudgels for the Old Believers party, was soon banished again, to Mezen, in northern Russia. The synod against the Old Believers (1666–67) sent him still farther north to Pustozersk, near Naryan-Mar. In the prison of the little fort there he wrote most of his works, the greatest of which is his *Zhitie* (*Life*), the first Russian autobiography (Eng. trans., 1941). It is distinguished for its lively description and its original colourful style and is one of the great works of early Russian literature. Avvakum was burned at the stake on April 14, 1682.

See N. K. Gudzy, *History of Early Russian Literature* (1949), Eng. trans. of 2nd Russian ed. (1941); P. Pascal, *Avvakum et les débuts du raskol* (1938).
(F. v. L.)

AWAJI-SHIMA, Japanese island with an area of 230 sq.mi. at the eastern end of the Inland sea, administratively a part of Hyōgo prefecture. Two narrow straits, Akashi strait to the north and Kii strait to the southeast, separate it from Honshu, while Naruto strait to the southwest separates it from Shikoku. Essentially mountainous (2,000 ft. the highest elevation), Awaji has one major plain which bisects it from east to west. This plain has the bulk of the population (198,808 in 1960) and agricultural land, the main city, Sumoto (48,497 in 1960), and the only railway line. Farmers specialize in dairying, vegetables, cut flowers and fruit, mainly for sale in Osaka-Kobe markets. Fishermen from small villages along the east and west coasts extract a rich haul of fish and shellfish from the Inland sea. Awaji has only a few small-scale consumer goods industries. (J. D. Ee.)

AWAN, a city of ancient Elam (*q.v.*), prominent throughout early Sumerian and Akkadian history in the second half of the 3rd millennium B.C. Although it was probably situated near Susa, its exact location is unknown. (G. G. Ca.)

AWE, LOCH, the longest fresh-water lake in Scotland, is situated in mid-Argyll, about 117 ft. above sea level. It has an area of nearly 16 sq.mi. and is 24 mi. long northeast to southwest from Kilchurn castle to Ford, its breadth varying from ½ to 3 mi. Its majestic northern end, dominated by the eastern skirts of the Ben Cruachan massif, is crescentic, one arm running toward Glen Orchy, the other to the point where the river Awe leaves the lake, reaching Loch Etive, a sea loch, by the impressive gorge of the Pass of Brander. The scenery around the southern end is much gentler. Inishail Island ("isle of rest"), burial ground of the Macarthurs, contains ruins of a church and convent.

(A. T. A. L.)

AXHOLME, ISLE OF, a rural district in the Gainsborough parliamentary division of Lincolnshire, Eng., bounded west by Yorkshire, south by Nottinghamshire and east by the river Trent. A flat, alluvial tract about 18 mi. by 5 mi., it is almost entirely under 100 ft. in elevation. The rural district consists of 13 parishes with an area of 79.9 sq.mi. and a population (1961) of 14,110.

In 1627 Charles I, then lord of the island, made a contract with Cornelius Vermuyden, a Dutchman, for reclaiming the meres and marshes. (*See* FENS.) This undertaking led to a large number of Flemish workmen settling in the district and, in spite of the violent measures adopted by the English peasantry to expel them, they retained their ground in sufficient numbers to affect the physical appearance and accent of the inhabitants to this day.

The principal towns are Epworth, the birthplace of John and Charles Wesley, and Crowle. The land is extremely fertile and produces heavy crops.

AXINITE, a mineral consisting of a complex aluminum and calcium iron borosilicate. The mineral was named from the Greek word for "ax" because of the characteristic thin wedgelike form of its crystals. The colour is usually clove-brown, but occasionally the mineral has a violet tinge. Handsome specimens are afforded by the beautifully developed transparent crystals found at Le Bourg d'Oisans in Dauphiné in France. The hardness of 6.5 to 7, combined with the colour and transparency, renders axinite applicable for use as a gem stone, the Dauphiné crystals being occasionally cut for this purpose, and it is regarded as a semi-precious stone. The specific gravity of axinite is 3.28. The chemical formula is $HCa_2(Mn,Fe)BAl_2Si_4O_{16}$. The iron may be replaced by manganese, yielding the form manganaxinite, and the aluminum by ferric iron.

AXIOM. According to Aristotle, every demonstrative science must start from indemonstrable principles. Among these first principles some are peculiar to the particular science but others are common to all sciences and are called axioms. Elsewhere the axioms are characterized as the common opinions from which all demonstration proceeds, and as those things which anyone must hold who is to learn anything at all.

In the *Elements* of Euclid the first principles are listed in two categories, the *postulates* and the *common notions*. The former are the principles peculiar to the particular science of geometry and seem to be thought of just as required assumptions since their statement opens with the word *etestho* ("let there be demanded"). The common notions are evidently the same as Aristotle's axioms, and indeed Proclus (*q.v.*), *On the First Book of Euclid*, tells us explicitly that the two terms are synonymous. However, the principle by which the division between postulates and axioms is to be made seems to have been not very certain; Proclus debates various accounts of it, but among them, that postulates are peculiar to geometric subject matter, while axioms are common, either to all sciences that are concerned with quantity or to all sciences whatever.

In modern times mathematicians have often used the words "postulate" and "axiom" as synonymous. But a distinction which recommends itself as useful, and in part historically justified, is to reserve the name "axiom" for the axioms of logic (*see* LOGIC), and to use "postulate" for those assumptions or first principles (beyond the principles of logic) by which a particular mathematical discipline is defined.

For examples of particular systems of mathematical axioms (or better, postulates) *see* the article POSTULATE.

AXIS, OPTIC, the direction in a crystal along which the ordinary and extraordinary rays are propagated with the same velocity.

See LIGHT: *Double Refraction;* CRYSTALLOGRAPHY: *Optical Crystallography.*

AXMINSTER, a small market town in Devon, Eng., lies on the Axe river, 26 mi. E. of Exeter by road and rail. In 1953 the urban district of Axminster ceased to exist and it was transferred to the rural district. Pop. of rural district (1961) 14,350. Axminster lies at the intersection of two ancient roads, the Portway and the Fosse Way. Its history dates from about 660 when it was one of the earliest settlements in the Saxon occupation of Devon. Axminster was founded soon after 705. The parish church of St. Mary the Virgin, which stands in Trinity square, the centre of the town, has a Norman doorway and Early English and Perpendicular work; its 13th-century tower was damaged in 1644 when Roundheads from Lyme Regis attacked Cavaliers inside the church. On alternate Thursdays an agricultural market is held in the square—an ancient privilege—and nearby is the cattle market. Axminster's best-known industry is carpetmaking (*see* CARPET MANUFACTURE). The carpet factory, founded in 1755, was closed in 1835; a new factory was built in 1937.

Ashe house, 2 mi. S.W., was the home of the Drake family and was rebuilt by Sir John Drake in 1670–80. John Churchill, 1st duke of Marlborough, whose mother was Elizabeth Drake, was probably born there. Only minor fragments remain of Newenham abbey, a magnificent Cistercian monastery founded in 1246 by Reginald de Mohun and dismantled after the Dissolution.

BY COURTESY OF R. R. HUMPHREY

ADULT AXOLOTL (AMBYSTOMA MEXICANUM) RETAINING LARVAL GILLS

AXOLOTL, a permanently larval salamander from Lakes Xochimilco and Chalco in Mexico. Its scientific name is *Ambystoma* (or *Siredon*) *mexicanum.* The popular name of axolotl is applied in a broad sense to any neotenic salamander (*i.e.,* one that matures sexually in the larval stage) of the family Ambystomatidae, a group found mainly in the ancient lakes of the Mexican plateau and in the western part of the continental United States.

Ambystoma mexicanum is a

black-speckled, dark-brown salamander with weak limbs, sharply pointed digits and external gills directed forward. Axolotls grow to a larger size than ordinary larvae of the family, sometimes reaching a length of 10 inches. They eat small animals, including others of their kind. In Mexico they are sold as food, and biological laboratories use them for experimental studies.

Ambystoma mexicanum has long been of interest because in captivity it may occasionally metamorphose into a gill-less form similar to the widespread tiger salamander (*A. tigrinum*). In nature the larval state seems obligatory as a result of hereditary factors, which probably influence the thyroid and pituitary glands, and environmental features such as temperature and chemical content of the water. This neoteny presumably promotes species survival where conditions would be difficult for a terrestrial adult, as on the arid Mexican plateau.

See AMPHIBIA; METAMORPHOSIS.

See J. A. Tihen, "Comments on the Osteology and Phylogeny of Ambystomatid Salamanders," *Bulletin Florida State Museum*, 3:1–50 (1958); E. H. Taylor, "A Bibliography of Mexican Amphibiology," *Kans. Univ. Sci. Bull.*, 31, pt. ii, pp. 543–89 (1947). (G. B. R.)

AXON (AXONE), also called the axis cylinder process, neurite, neuraxis and neuraxon, is a process of the nerve cells. As a rule it has as a sheath a fatty substance called myelin. Its usual function is to conduct impulses away from the cell or neuron. *See* NERVOUS SYSTEM; SYNAPSE. (F. L. A.)

AXUM: *see* AKSUM.

AYACUCHO, a department in the highlands of south central Peru (pop. [1958 est.] 572,559; area 17,569 sq.mi.) bounded north by Junín, west by Huancavelica and Ica, south by Arequipa, east by Apurímac and Cuzco (*qq.v.*). It is largely a region of high plateau, interspersed with valleys, drained by the Apurimac and its tributaries. Lake Parinacocha, 12 mi. long and 6 mi. wide, lies in the south of the department. Cattle and sheep graze in the area, and cereals, maize, potatoes, grapes and sugar cane are cultivated there. Industries include the manufacture of woolen textiles, sugar, wine and alcohol. Silver, nickel, cobalt, copper, manganese, sulfur and asphalt are important mineral resources. The population is chiefly Indian and mestizo. The city of Ayacucho (*q.v.*) is the capital of the department. (J. L. TR.)

AYACUCHO, a city in the highland region of south central Peru (pop. [1958 est.] 26,650), capital of the department of the same name and of the province of Huamanga. Founded in 1539 by Francisco Pizarro (*q.v.*), it was known as Huamanga until 1825. The city gained its present name from the plain of Ayacucho (meaning "corner of death" in Quechua), which lies near Quinua, the scene of the decisive defeat in 1824 of the royalist forces by the revolutionaries under command of Gen. Antonio José de Sucre (*q.v.*).

Ayacucho lies in a fertile valley at 8,987 ft. above sea level in latitude 13° 6′ S. Important archaeological ruins are found near the city. The climate is pleasant and invigorating. Crops cultivated in the district include cereals, maize, potatoes, grapes and sugar cane; cattle and sheep graze in the area. Significant industrial products of Ayacucho are filigree ware, woolen textiles, wine, alcohol, pottery and leather goods. Mineral resources of the region comprise silver, nickel, cobalt, copper, manganese, sulfur and asphalt. The city, seat of a bishopric, contains a cathedral and many churches. The Colonial university that functioned in Ayacucho until the 1880s was reopened in 1958. Ayacucho is on the highway between Lima and Cuzco approximately midway between these cities in a total distance of 720 mi. Ayacucho may also be reached by air. The nearest railhead is at Huancavelica. (J. L. TR.)

AYACUCHO, BATTLE OF, won by the "patriots" on Dec. 9, 1824, freed Peru and sealed Spain's doom in the new world. The revolutionary forces numbering about 6,000 men, among them Venezuelans, Colombians, Argentines and Chileans as well as Peruvians, were under the leadership of Simón Bolívar's outstanding lieutenant, the Venezuelan Antonio José de Sucre (*q.v.*). He opened the attack with a brilliant cavalry charge led by the daring Colombian José María Córdoba, and in a short time the Spanish army of over 9,000 was nearly annihilated. The terms of surrender provided that all Spanish forces would be withdrawn from both Peru and Charcas (Bolivia). The last of the Spanish soldiers departed from Callao, the port for Lima, in Jan. 1826. *See* PERU: *History*. (J. J. J.)

AYALA, BALTASAR (1548–1584), Spanish jurist, was born in Antwerp during the subjection of the Low Countries to the throne of Spain and was auditor general in the army sent by Philip II to suppress the rebellion of the states-general. His work *De jure et officiis bellicis et disciplina militarii* ("On the Law and Duties of War and Military Discipline"), published in 1582, is devoted partly to a discussion of the law of war in general, including the conditions of a just war, and partly to the application of the law of war to actual military operations. While his principles of a just war were a contribution to greater restraint in relation to the conduct of hostilities, his conception of the rights of the monarch was reactionary and his denial of the application of the law of war to rebels is in strong contrast with the more humanitarian ideas of Francisco de Vitoria.

See *De jure et officiis bellicis et disciplina militarii*, trans. by J. P. Bate, in "Classics of International Law"; James Brown Scott, *Law, the State, and the International Community*, vol. I, ch. xxiv (1939). (C. G. FX.)

AYALA, PEDRO LÓPEZ DE: *see* LÓPEZ DE AYALA, PEDRO.

AYALA Y HERRERA, ADELARDO LÓPEZ DE (1828–1879), Spanish dramatist and politician, whose most distinctive achievement is in his comedies of contemporary manners, was born at Guadalcanal, Seville, May 1, 1828. While still young, he enjoyed success as a playwright and this led to political advancement. Being without firm political convictions, he found little difficulty in changing party. Thus he was prominent in the revolutionary movement to drive the Bourbons from the throne in 1868, but took office when they were restored, becoming eventually president of the *Cortes*.

Ayala died in Madrid, Dec. 30, 1879.

His plays are of three kinds. The earliest, notably *Un hombre de estado* (1851) and *Rioja* (1854), which are set in the royal court of 17th-century Spain, are historical verse dramas. He also wrote *zarzuelas* (musical plays), mostly with a historical background, and sometimes, *e.g.*, *El conde de Castralla* (1856), containing satirical allusions to current politics. In his later work—*El tejado de vidrio* (1856), *El tanto por ciento* (1861), *El nuevo don Juan* (1863) and *Consuelo* (1878)—the moralizing tendency, already apparent in his first plays, is more pronounced, and there is an attempt at realistic presentation of the upper and middle classes of 19th-century Spain. The realism is timid, however, and the satire is in general moral rather than specific social terms. Self-seeking and sexual licence are its conventional targets. *Consuelo*, his finest play in spite of a somewhat contrived plot, is a natural and impressive portrayal of a girl who suffers the consequences of her rejection of a worthy but poor suitor for a wealthy scoundrel. (H. B. HL.)

AYDIN (AIDIN), the centre and a chief town of the *il* (province) of the same name in southwestern Turkey, about 70 mi. E.S.E. of Izmir with which it is linked by railway. Pop. (1960) 35,671. It lies on the lower slopes of hills overlooking the fertile valley of the Buyuk Menderes (anc. Maeander) river, and on a nearby height are the ruins of the ancient Tralles (*q.v.*). It is an important trading centre for the crops grown in the neighbouring plain; the chief products are olives and olive oil, dried figs and grapes, tobacco and cotton. It also exports licorice and acorns of valonia oak used for tanning.

Aydin was taken by the Seljuks, Aidin and Mentesh late in the 13th century, and about 1390, when ruled by Isa Bey, a descendant of Aidin, acknowledged Ottoman suzerainty. In the Seljuk period it was only a secondary city. The town suffered severely in the Greco-Turkish conflict of 1919–22.

The *il* of Aydin (pop., 1960, 469,888; area 2,957 sq.mi. includes the greater part of the Buyuk Menderes valley and its mountainous borders to north and south. It is densely populated and one of the most important agricultural areas of Turkey, its chief crops being figs, olives and cotton. Nazilli, about 30 mi. E. of

Aydin, is a centre of the cotton textile industry.

(N. Tu.; S. Er.; E. Tu.)

AYE-AYE, the most remarkable of all the Malagasy lemurs. The aye-aye, *Daubentonia madagascariensis*, has a broad rounded head, short face, large eyes, large hands and long thin fingers with pointed claws, of which the third is remarkable for its extreme slenderness. The foot resembles that of the other lemurs in its large opposable great toe with a flat nail; but all the other toes have

THE ZOOLOGICAL SOCIETY OF LONDON

AYE-AYE (DAUBENTONIA MADAGASCARIENSIS)

pointed compressed claws. The tail is long and bushy. The general colour is dark brown, the outer fur being long and rather loose, with a woolly undercoat. It is nocturnal in its habits, living alone or in pairs in the bamboo forests. It feeds on juices, especially of the sugar cane, which it obtains by tearing the stalk with its strong incisor teeth; but it also devours wood-boring caterpillars, which it obtains by cutting their burrows with its teeth and picking them out of their retreat with the claw of its attenuated middle finger. It constructs large ball-like nests of dried leaves, lodged in a fork of the branches of a large tree, and with the opening on one side. *See* PRIMATES: *Lemurs: Lemuriformes.*

AYLESBURY, a municipal borough and the county town of Buckinghamshire in the Aylesbury parliamentary division, 39 mi. N.W. of London by road. Pop. (1961) 27,923. Area 5.1 sq.mi. An important market town, it stands on a low hill in the vale of Aylesbury, a rich agricultural district once renowned for its ducks. Its industries include printing, food products, rivet manufacture and light engineering.

Aylesbury (Saxon Aegelsburh) was the centre of a hundred (*q.v.*) before the Conquest and in 1239 Henry III granted it an annual fair at the feast of St. Osyth. Queen Mary's charter of 1554 constituted it a free borough but it was not until 1916 that it was incorporated. The 12th- to 13th-century church of St. Mary, built on an earlier site, crowns the hill and stands in a square of 17th- to 18th-century houses. The narrow streets of the old town converge upon the market square where stand the county hall (1720), in which the assizes, quarter and petty sessions are held, and the King's Head hotel (15th century), which belongs to the National Trust. The old building of Aylesbury grammar school (1598) is now part of the county museum. The school moved to new premises in 1906.

AYLESFORD, HENEAGE FINCH, 1ST EARL OF (1649?–1719), English lawyer prominent in the reign of James II, was the second son of Heneage Finch, 1st earl of Nottingham. Educated at Westminster school and at Christ Church, Oxford, he was appointed solicitor general in 1679, being returned to parliament that year for Oxford university, and in 1685 for Guildford. He represented the crown in the attack upon the corporation of London (1682) and the next year in the prosecution of Lord William Russell, when, according to G. Burnet, "he showed more of a vicious eloquence in turning matters with some subtlety against the prisoners than of strict or sincere reasoning." In the trial of Algernon Sidney (1684), he supported the opinion of Lord Chief Justice Jeffreys that *scribere est agere*, arguing that the unpublished treatise of the accused was an overt act. The same year he was counsel for James II in his successful action against Titus Oates for libel, and in 1685 prosecuted Oates for the crown for perjury. Finch, however, though a Tory and a crown lawyer, was a staunch churchman, and on his refusal in 1686 to defend the royal dispensing power he was summarily dismissed by the king. As leading counsel for the seven bishops (1688) he argued that such a power was "a power to abrogate law," which "is as much a part of the legislature as a power to make laws." He sat again for Oxford university in the Convention parliament of 1689–90 and in all the following assemblies, except that of 1698, until 1703.

He was one of the few who in the house of commons opposed the famous vote that James II had broken the contract between king and people and left the throne vacant. In 1689 he joined in voting for the reversal of Lord Russell's attainder and endeavoured to defend his conduct in the trial, but was refused a hearing by the house. He held no office during the reign of William III, but in 1703 he was raised to the peerage and made a privy councilor. After the accession of George I in 1714, he was created earl of Aylesford and appointed chancellor of the duchy of Lancaster. He died on July 22, 1719. (G. H. J.)

AYLESFORD, a village in the Sevenoaks parliamentary division of Kent, Eng., 3½ mi. N.W. of Maidstone. Pop. (1961) 5,278. It was the first point at which the Medway could be forded, and Bede states that Vortigern here fought Hengist and Horsa in 455. The river is crossed by a modernized 14th-century bridge. About a mile northeast are two megalithic tombs, Kit's Coty house, consisting of three upright stones and a capstone, and the Countless Stones. Aylesford cemetery bears witness to the Belgic invasions (about 75 B.C.). The church of St. Peter, on a hill above the Medway, dates from Norman times and a Carmelite friary, founded in 1242, has been restored to its original purpose. Preston hall, the ancient home of the Colepepers, is a hospital for tubercular patients and attached to it is a village settlement for their rehabilitation run by the British Legion and known as "British Legion village." The main occupations of the Aylesford people are quarrying, paper-making and agriculture.

AYLLÓN, LUCAS VAZQUEZ DE (*c.* 1475–1526), Spanish explorer and colonizer of South Carolina, was born in Toledo of a wealthy family. In 1502 he accompanied Nicolás de Ovando to the West Indies island of Hispaniola and became judge in the colonial administration of the island. In 1520 he went to Mexico with the intention of mediating the dispute between Cortés and Diego Velázquez over the observance of royal orders in New Spain. An expedition sent by him under command of Francisco Gordillo made a landfall near Cape Fear on the North American continent in 1522 and the following year Ayllón went to Spain to secure a royal charter for the exploration and settlement of that coast. He was authorized by Charles V to explore 800 leagues of territory taking special pains to find a strait to the Spice Islands. In the early summer of 1526 Ayllón sailed from Hispaniola to found a settlement, probably at the mouth of the Pee Dee river, called San Miguel de Guadalupe. (Little credence can be given to the claim that the settlement was made at Jamestown, Va.) The colony was ill-fated, however, and abandoned after Ayllón and many men had died in a fever epidemic. He left two manuscripts later used by Peter Martyr.

See W. Lowery, *The Spanish Settlements Within the Present Limits of the United States 1513–1561* (1911). (U. S. L.)

AYLMER, JOHN (1521–1594), bishop of London, distinguished by his thorough enforcement of the Elizabethan act of uniformity in his diocese, was born at Aylmer hall, in Norfolk. About 1541 he was made chaplain to the duke of Suffolk and tutor to his daughter Lady Jane Grey. He became archdeacon of Stow in 1553, but his opposition in convocation to the doctrine of transubstantiation soon led to his deprivation. From exile in Switzerland he wrote a reply to John Knox's famous *Blast Against the Monstrous Regiment of Women* under the title *An Harborowe for Faithfull and Trewe Subiectes* (1559). On the accession of Elizabeth he returned to England. He became archdeacon of Lincoln in 1562, when he was a member of the convocation that reformed and settled the doctrine and discipline of the Church of England. In 1577 he was consecrated bishop of London, and thereafter made himself notorious by his harsh treatment of all who differed from him on ecclesiastical questions, whether puritan or papist. He is attacked in the Marprelate tracts (1588; *see* MARPRELATE CONTROVERSY) and is characterized as "Morrell," the bad shepherd, in Edmund Spenser's *The Shepheardes Calender.* He died on June 3, 1594.

See the eulogistic life by J. Strype (1701). (G. Hu.)

AYMARA, a large South American Indian group living in the vast windy 12,500-ft.-high Titicaca plateau of the central Andes, between the western Maritime Cordillera and the eastern snow-capped Cordillera Real, and southward to Lake Poopó and the salt marshes of Uyuni. In colonial times the Aymara tribes were the Canchi, Colla, Lupaca, Collagua, Ubina, Pacasa, Caranga, Charca, Quillaca, Umasuya and Collahuaya, their territories corresponding largely to modern Bolivian political divisions of similar name. Additionally, Aymara was anciently spoken in the provinces of Lipes and Chichas (southern Bolivia), Arica (northern Chile), and southern portions of the departments of Cuzco, Apurímac and Ayacucho (southern Peru). Modern Aymara number 600,000 in Peru and Bolivia (*see* BOLIVIA: *The People;* PERU: *The People*).

Basically agriculturalists and herders, the Aymara live in an area of poor soil and harsh climate. Trees are rare; coarse grass gives pasturage for llama and alpaca herds; fuel is of the semi-subterranean *tola* brush or llama dung. Some fish are taken with nets in the lake and its southern outlet, the Río Desaguadero. The uncertainty of life on the harsh, raw plateau has led the Aymara to develop much magic to control natural phenomena and to assure food from crops, flocks and fishing.

The builders of the huge stone ruins at Tiahuanaco were unknown by the colonial period, though they were doubtless ancestors of the Aymara; the influence of the pre-Incan Tiahuanacan culture may be seen archaeologically as far as the Pacific coast. The pre-Incan period of the *Chullpas* (corbelled tower graves of chiefs and other important people) was one of independent, warring Aymara states, the most important being those of the Colla, capital Hatuncolla, and the Lupaca, capital Chucuito. About 1430 the Inca emperor Viracocha began conquests southward from his capital at Cuzco. Former Aymara territories ultimately formed a major part of the Inca empire, against which the Aymara continually revolted. In the Inca civil war, the Aymara supported Huascar against Atahualpa.

The Spanish conquest began in 1535 under Diego de Almagro. Seekers of gold and serfs were followed by Dominican and Jesuit friars seeking converts, present-day Aymara being nominally Catholic. The Spanish *encomienda* economy for food production, household serfs, miners and coca plantations was based on the native *ayllu*, a loosely patrilineal land-owning group or *communidad*. Exploitation reached its height under the viceroy Toledo, and the period of rebellion begun in 1780 ended with independence of the Spanish crown in 1821.

Aymara were the first cultivators of the misnamed "Irish" or white potato, of which they had over 200 named varieties, and most of which were made into frost-dried *chuñu*, an Aymara staple. They also had 10 varieties of oca (*Oxalis tuberosa*), 5 of ullucu (*Ullucus tuberosus*), 6 of the spinach-family seed-grain quinoa (*Chenopodium quinoa*), 2 of kañawa (*Chenopodium* spp.) and 6 of corn (*Zea mays*), which last they did not originate and which grows poorly in the cold dry *altiplano*. European beans (*Vicia faba*), barley and wheat have been added since the conquest. Men dig, plow, fertilize and thresh, but women plant. In ancient times there was some irrigation, manuring and crop rotation, and to a lesser extent there is today. Herding of llamas and alpacas is done by women and children; llamas are used as beasts of burden, their flesh, rarely eaten, being dried into *charqui* ("jerky"); alpacas are used for their fine wool from which Aymara women spin and weave sturdy warm clothing. Fishing is from *balsas, i.e.,* cigar-shaped, giant totora-reed rafts, poled or mat-sailed, using dragnets, dip nets and fish fences.

Aymara clothing copies in crude homespun earlier Spanish colonial models. Men wear conical, ear-flapped, knit wool *gorros;* women wear round, native-made wool derbies, with wool wimples in cold weather. Aboriginally, Aymara deformed their heads into the spectacular "sugar-loaf" form by binding in infancy. The single-room, rectangular, gabled Aymara house, about eight by ten feet in size, is made of turf, with wild grass thatching over pole rafters, with a family sleeping platform of mud at one end and a clay stove near the door.

Pottery, weaving, metal- and leatherwork are all crude even by earlier colonial, and certainly by Tiahuanacan, standards.

Aymara religion consists in alcohol and llama-blood libations to the earth goddess Pachamama, to the Spirit of the Lake and to the Pampa spirit, supernatural "owner" of the animals. Thunupa is the god of lightning, much feared by the Aymara. Their world is densely populated with other spirits also: *waka* which are either good or evil; *achachilas* or locality demons causing sickness by soul kidnaping; *supaya* or evil demons; a beautiful young woman demon causing insanity; an evil hag who brings epidemics; a three-headed water monster of Lake Titicaca; and dangerous nocturnal flying heads. The Aymara have many categories of magicians, diviners, medicine men and witches to cope with these supernaturals. Their *materia medica*, mostly of plant origin numbers over 400 items, including quinine for fever, mercury pomade for syphilis, and many others, some of which are probably effective medically.

AYODHYA (AJODHYA), an ancient city of India on the Gogra river near Fyzabad, Uttar Pradesh, is one of the seven sacred Hindu shrines, for in antiquity it was the magnificent (96 mi. perimeter) capital of Dasharatha, king of Kosala and father of Rama, the eponymous hero of the *Ramayana*. The temple marking the site of Rama's birth was converted by the Mogul emperor Babur into a mosque, although the Hanumangarh and Kanak Bhavan temples are still in use by Ramaite Vaishnavas. Several bathing ghats are associated with the Rama legend, as are the flocks of red monkeys still ubiquitous in the town. (*See* RĀMĀYANA.)

Kosala has claims to be the birthplace of the founders of Buddhism and Jainism, and a period of Buddhist supremacy obtained in Ayodhya until its restoration by Chandra Gupta II (Vikramaditya) *c.* 57 B.C., and the revival of Hinduism; even in the 7th century the Chinese traveler Hsüan Tsang recorded 20 Buddhist temples with 3,000 monks there. Apart from the temples named above, Ayodhya is largely in ruins, and the modern town is insignificant. (J. B.-P.)

AYR, a royal and parliamentary burgh, county town of Ayrshire, Scot., and seaport at the mouth of the river Ayr, 33 mi S.S.W. of Glasgow by road. Pop. (1961) 45,276. It receives its name from the river; *ar* or *ad'har* in Gaelic signifies clear or rapid, also shelving and fordable. The burgh embraces Newton-on-Ayr, Wallacetown, Whitletts and Alloway and its boundaries stretch from Prestwick to the river Doon. Newtown is a burgh of barony with charter said to have been granted by King Robert the Bruce to 48 inhabitants who had fought at Bannockburn. Ayr was created a king's burgh (renamed royal burgh in the 15th century) by William the Lion in 1202. He built a castle (of which nothing remains) and made it a garrison town and the court town of the sheriffdom of Ayr, which it still is. During the wars of Scottish independence, the town was the scene of many of William Wallace's exploits. In the church of St. John, the Scots parliament met in 1315 after the victory of Bannockburn to confirm Bruce and his family in possession of the crown of Scotland. As a result of the Reformation, the two monasteries in Ayr were suppressed and the citizens developed strong Presbyterian tendencies. Later when Cromwell subdued Scotland he built a fort, including the tower of St. John near the harbour, known as Cromwell's fort. In the 18th century Ayr was a small town congregating round the High street, the Sandgate and the adjoining Vennels. By the mid-19th century it had become a social centre and watering place for the Scottish gentry. The establishment of new industries, stimulated by the opening of the Glasgow-Ayr railway in 1840, did not completely alter its appearance, as they were sited north of the river, in Newton-on-Ayr and Wallacetown. The oldest among them are metalworking and engineering, which have been carried on for more than a century. Others include drop-stamping and stamping works; light engineering; the making of agricultural implements, chemicals, fertilizers; textiles and carpets; boots and shoes; and furniture. In 1935 the burgh was extended to include Whitletts and Alloway.

Ayr proper lies on the south bank of the river, which is crossed by three road bridges and two railway bridges. Between the Sandgate and the harbour is Loudoun hall (16th century, restored), the town house of the Loudouns, for long sheriffs of Ayr. Near the town centre is the beach where the Low green is fronted by a 2½-mi.-long esplanade.

In the middle ages Ayr was the chief Scottish port on the west coast, but was later superseded by the new ports farther up the Clyde. The harbour has 36,000 ft. of wharves and can take vessels with a draught of 21 ft. Port equipment includes a coaling conveyor and electric cranes and steam cranes up to 40 tons capacity. A slipway 850 ft. long capable of handling vessels up to 2,000 tons is within the harbour area. Coal is exported, mainly to the Irish ports. Facilities are also available on the south quay for the landing and marketing of fish. Ayr is an important market centre and large cattle sales are held weekly. The Ayrshire Agricultural show is held annually in April on the racecourse, near Whitletts, and lasts two days. Ayr is also reckoned as the Newmarket of Scotland and many meetings are held on the new racecourse.

Two local weekly newspapers are published, the *Ayrshire Post,* established in 1880, and the *Ayr Advertiser,* which first appeared in 1803. Of the 12 schools accommodating 7,000 pupils, Ayr academy, dating from 1233, is the most notable, with approximately 1,000 pupils. Robert Burns was born at Alloway (*q.v.*) and spent most of his life in the vicinity. The corporation owns two scenic estates at Belleisle and Craigie park which are administered for the benefit of the public. (W. R. W.)

AYRE, SIR AMOS LOWREY (1885–1952), British shipbuilder who enjoyed international prestige, combining fullest technical knowledge with practical experience, was born at South Shields, Durham, on July 23, 1885. He was educated at Armstrong college, Newcastle upon Tyne, where he distinguished himself in naval architecture. After World War I he joined his brother in founding the successful Burntisland Shipbuilding company, of which he was chairman until 1936. Ayre showed keen interest in international work for the industry, and in 1928 represented British shipbuilding and acted as chairman at the League of Nations committee on international shipbuilding statistics. During 1930–31 he was president of the Shipbuilding Employers' federation, and subsequently left his firm to become permanent chairman of the industry's national commercial organization, the Shipbuilding conference. During World War II he was director of merchant shipbuilding at the admiralty. Knighted in 1937, Ayre was made a knight of the British Empire in 1943. He died in London on Jan. 13, 1952. (R. B. Sh.)

AYRER, JAKOB (1544?–1605), prolific German dramatist of minor talents, was probably born in Nürnberg. The date is uncertain, but it may have been in March 1544. He moved to Bamberg in 1570, returning to Nürnberg in 1593. A lawyer by profession, by the time he died (at Nürnberg, March 24 or 26, 1605) he was a member of the city council and an imperial notary.

Apart from his *Bamberg Chronicle* and a version of the Psalter, both on traditional lines, Ayrer wrote over 100 plays; 30 tragedies and comedies and 36 *Fastnachtsspiele* (Shrovetide farces) and *Singspiele* are printed in his *Opus theatricum* (1618). As a dramatist he is the successor of Hans Sachs, resembling him in versification and diction, in the simplicity of his character-drawing, his moralistic attitude and the undramatic, narrative quality of his dialogue. But unlike Sachs at his best, his plots tend to lose themselves in endless episodic detail. The Englische Komödianten (troupes of English actors who performed crude but theatrically effective versions of Elizabethan plays in Germany in the late 16th and early 17th centuries) taught Ayrer to concentrate on outward action, sensational incidents and spectacular effect; the "English" clown replaced the traditional fool and appeared even in serious plays. English jigs were models for his *Singspiele,* with strophic texts sung to traditional tunes, while the "English" repertory provided new subjects. Other subjects range from Germanic legend, Livy and Boccaccio to comic anecdotes of daily life. Despite some new features, Ayrer essentially represented the end of an older tradition and had no direct successors.

Bibliography.—*Ayrers Dramen,* ed. by A. von Keller, 5 vol. (1865). *See* also W. Wodick, *Jakob Ayrers Dramen* (1912); G. Höfer, *Die Bildung Jakob Ayrers* (1929); W. Stammler, *Von der Mystik zum Barock,* 2nd ed. (1950). (J. R. We.)

AYRSHIRE, a southwestern county of Scotland, is bounded on the north by Renfrewshire, on the east by Lanarkshire, Dumfriesshire and Kirkcudbrightshire, on the south by Wigtownshire and on the west by the Firth of Clyde. Area 1,132 sq.mi.; pop. (1961) 342,855.

Physical Features.—The shore curves southward from Wemyss Bay on the narrow, middle part of the Clyde estuary and then in a great bight to the mouth of Loch Ryan. The land rises from a coastal plain to an eastern boundary linking hill groups of from 1,200 to 2,000 ft. Thus the county roughly resembles a crescent-shaped piece of saucer, concave to the west around Ayr bay and Irvine bay. To these bays flow most of the rivers along roughly radial courses. From north to south they are the Garnock, Irvine, Ayr (the longest, 38 mi.), Doon, Girvan and Stinchar. Rivers divide Ayrshire into three districts (former baileries, see *History* below)—Cunninghame north of the Irvine, Kyle between Irvine and Doon and Carrick south of the Doon. The many lochs, the chief being Doon, Finlas and Bradan, provide water for the whole area. There are three islands, including Ailsa Craig (*q.v.*), a large inhabited rock of intrusive riebeckite-microdiorite reaching 1,114 ft. above mean sea level.

On the eastern rim, high moorland comprises about one-third of the county. This is wind-swept country of curlew and grouse with large farms and wide views across the lowlands to the firth and the hills beyond. The mean annual rainfall is commonly 60–100 in. The vegetation varies with slope, etc., between acid grasslands (fescue and purple moor grasses with matgrass, heather and bracken), wet grass moor (*Molinia,* sedges, etc.) and peat mosses with cotton grass, deer grass and sphagnum. The highest moors lie in the southern uplands (southeast of the main and branch faults running from New Cumnock to Girvan), mostly over Ordovician shales and grits, lightly metamorphosed in the Caledonian orogenesis; Shalloch on Minnoch (2,520 ft.) and Kirriereoch (2,565 ft.) are part of the metamorphic aureole around the Merrick granite boss in Kirkcudbrightshire. Outliers of these high plateaus in eastern Kyle and Cunninghame, and in the Kilbirnie hills farther north, are separated by valleys leading through to Glasgow and Clydesdale. Much of this country consists of Carboniferous basalts, with some Silurian inliers.

More than half of Ayrshire is rolling lowland between 100 and 1,000 ft. above sea level. Plateau surfaces are planed across a synclinal structure, including important coal-yielding Carboniferous rocks, complicated by faulting and igneous intrusions which make mining difficult. In the centre are productive Coal Measures, overlain in places by barren Red Measures and by red Permian sandstone, much used for building. Rolling boulder clay cover gives light but fertile soils in Cunninghame, derived largely from Old Red Sandstone and basalts, but colder and heavier soils in Kyle, including much Carboniferous material. A mean annual rainfall of 40–50 in. in a mild, drizzly climate gives luxuriant growth. This is a soft, gentle landscape of whitewashed houses, sometimes still thatched, amid trim fields of fodder crops and ley, interrupted by the large manufacturing town of Kilmarnock or industrialized valleys like that of the upper Irvine.

Fringing the shore are, first, sand dunes with bent grass, attractive to vacationers, then turfy "links" on the sand-apron, largely turned into golf links, and inland postglacial raised beaches mainly at about 25 and 100 ft. above sea level, which yield well-drained easily warmed soils, responding to intensive cultivation for early potatoes, strawberries, etc., if well fertilized. The climate is mild (January mean 40°–42° F.) and fairly sunny (January mean more than 1 hr. per day, August 4½ hr.), with moderate rainfall (largely less than 35 in. mean annual). The low incidence of fog (less than 5 days per year on the average) is of importance to Prestwick airfield. (A. T. A. L.)

History.—Various small prehistoric finds show that the county has been continuously inhabited for 6,000 years. The only trace

of Roman penetration against the tribe of the Damnonii is the site of a fort, built during Agricola's invasion of Caledonia (A.D. 79–84), near Loudoun hill. During the dark ages the tribal kingdom of the Strathclyde Britons occupied southwestern Scotland. In 1034 it was included in the rudimentary kingdom of Scotland and its king Duncan became the first king of all Scotland. Norman infiltration is visible in the still used parish church of Symington, first built in 1160, and in the great ruined castle at Dundonald, first built in 1135. Crossraguel abbey, 2 mi. S.W. of Maybole, founded in 1244, is the best preserved of the ruined monasteries.

Rudimentary royal administration of the shire began in the 12th century. Prestwick became a burgh of barony in 1165. By 1207 the sheriffdom of Ayr included the baileries of Cunninghame, Kyle (Kyle Stewart and King's Kyle) and Carrick. Between 1203 and 1206 Ayr and in 1372 Irvine became king's (later royal) burghs. The invading Norwegians were defeated at the battle of Largs (1263) by Alexander III. In 1297, at Ayr, William Wallace began the struggle to regain Scotland's independence from England. Robert Bruce, earl of Carrick, began his successful fight for the Scottish throne at his home, Turnberry castle, in 1307; he held a parliament at the church of St. John the Baptist, Ayr, in 1315. During the middle ages the great baronial families, such as the Kennedys of Dunure castle (now in ruins) and the Mures of Rowallan castle (still occupied), held sway. The Reformation (1560), including visits by John Knox, was accepted quietly and the monasteries were dissolved. To control southwestern Scotland, Oliver Cromwell built a citadel at Ayr in 1654. After the Covenanters' brief victory at the battle of Drumclog (1679), near Loudoun hill, their martyrs' graves show their suppression.

With the industrial revolution, Scotland's first deep coal mines were sunk at Stevenston in 1780; iron works were opened at Muirkirk in 1787; and factory textile production began at Catrine in 1787. The agricultural revolution brought enclosures, draining and crop rotation. In 1812 the duke of Portland built a horse-drawn tramway from his Riccarton (Kilmarnock) coalpits to his newly built harbour at Troon; and four years later he introduced on to it the first steam locomotive in Scotland.

Among notable men native to Ayrshire are: Robert Burns, the poet, born at Alloway (*q.v.*) in 1759; John Galt, the novelist; William Murdock, the inventor of coal gas; John Loudon McAdam, originator of the "macadamizing" of roads; John Boyd Dunlop, pioneer of the pneumatic rubber tire; and Sir Alexander Fleming, who discovered penicillin. Culzean (*q.v.*) castle, designed by Robert Adam in 1775, which is the home of the marquis of Ailsa and contains a flat given for life to former Pres. Dwight D. Eisenhower to commemorate his services in World War II, was presented to the National Trust for Scotland.

Population and Administration.—The population of Ayrshire in 1961 was 342,822; 57,552 more than in 1931. Ayr (45,276), the county town, and Kilmarnock (47,509) (*qq.v.*) are large burghs. The small burghs include Ardrossan (9,573), Irvine (16,911), Largs (9,104), Troon (9,927), Prestwick (*qq.v.*) (12,562) and Saltcoats (14,182). There are five parliamentary constituencies: Ayr and Kilmarnock burghs, and South, Central and North Ayrshire, the latter including Buteshire.

In each burgh the magistrates court deals with minor offences at common law, but serious offences are remitted to the sheriff court at Ayr. The lord lieutenant of the county has only the high ceremonial prestige of being the sovereign's personal representative. Local public services are administered by the town councils of the burghs and district councils of the country areas. County public services are organized by the county council from Ayr, though Ayr and Kilmarnock burghs maintain some of their own, *e.g.*, police and libraries.

Industries and Communications.—Ayrshire is one of the most important and best-developed agricultural counties in Scotland though farming employs less than 6% of the population. The lowland's lush meadows have the heaviest stock-carrying capacity in Scotland. In the early 1960s its numerous dairy farms with about 150,000 dairy cattle produced about one-fifth of Scotland's milk supply, all from T.T. or attested herds of the world-famous Ayrshire breed (*see* CATTLE) whose pedigree records are in Ayr, the main stock market. At Auchincruive, near Ayr, the West of Scotland Agricultural college's practical department, the Hannah Dairy Research institute and the Scottish Horticultural Research institute ensure scientific progress. There were about 30,000 beef cattle in the early 1960s. The raising of poultry and pigs is also significant. Tractors had all but replaced the Clydesdale draft horses by the early 1960s. There were about 450,000 mutton Blackface hill sheep and Border Leicester marginal land sheep. About 25% of the arable land is devoted to crops, mainly oats and turnips. The almost frost-free sandy soil near the coast produces large crops of Epicure potatoes, Scotland's earliest, and market gardens supply the industrial areas. Industries connected with agriculture include: butter, cheese, cream and powdered milk processing at Mauchline and Kilmaurs; the canning of vegetables at Kilwinning; one of Scotland's largest fertilizer plants at Ayr; the processing of seaweed into many commodities at Girvan; and the production of 90% of Great Britain's output of self-propelled combine harvesters at Kilmarnock.

The main industrial areas are the Irvine and Garnock valleys. The chief textile industry is woolen hosiery, with about 60 factories in Kilmarnock, Ayr, Irvine, Stewarton and Dalry, while carpets are made at Kilmarnock and Ayr, nylon at Kilmarnock and Stewarton, cotton at Catrine, linen at Kilbirnie, balmorals and Glengarries for Scottish regiments at Kilmarnock, blankets at Galston, Hollybush and Dunlop. Two-thirds of Great Britain's lace comes from Galston, Newmilns and Darvel. Kilmarnock, the industrial centre, has the largest hydraulic engineering plant in the commonwealth and makes ball bearings and agricultural machinery. Ayr also makes agricultural machinery and has one of Great Britain's largest drop forges and the country's only manufacturers of mounted hammer mills. Prestwick has aircraft engineering and construction works, Glengarnock steel mills and Ardeer (Stevenston) commercial explosive and chemical works, while Ardrossan petroleum refinery produces the biggest output of bitumen in Scotland. Ships are built at Ardrossan and Troon, repaired at Ardrossan, Troon and Ayr, and broken up at Troon. Mauchline (*q.v.*) makes curling stones, importing the rough material from Ailsa Craig, for export. Whisky is blended at Kilmarnock. Ayr, Kilmarnock and Maybole produce footwear, Beith furniture, and Kilmarnock and Hurlford earthenware.

Coal is exported from Ayr to Northern Ireland and from Troon to the western coastal areas of Scotland. The Central Ayrshire coal field, which provides the main occupation for many villages, has reserves estimated at 1,000,000,000 tons. The estimated annual production for the mid-1960s was more than 6,000,000 tons (about one-fifth of the total for Scotland), including 1,500,000 tons from each of the new mines near Ochiltree, at Killoch colliery and the Barony colliery, beside which is a 60-megawatt electricity generating station burning slurry. By the mid-1960s the Hunterston (West Kilbride) atomic power station was expected to produce 300 megawatts annually for the national grid. Bauxite and limestone are mined at Beith, whinstone at Dundonald, fire clay at Dalry and brick clay at Annbank, Dreghorn and Dalry.

The formerly important fishing industry was declining in the 1960s, though harbour facilities were improved at Ayr, Maidens, Girvan and Dunure. Popular seaside and golfing resorts are Largs, Saltcoats, Troon and Prestwick (championship courses), Ayr and Girvan. There is a modern holiday camp at the Heads of Ayr and there are racecourses at Bogside, near Irvine, which has the Scottish Grand National steeplechase, and Ayr, the "Newmarket of Scotland" with seven meetings annually.

Bus services cover many of the 1,500 mi. of roads. In the 1950s and 1960s new fast diesel trains served the main railway lines, which were to be electrified. The chief harbours are at Ardrossan, which can take vessels up to 14,000 tons, Ayr and Troon. Prestwick's almost fog-free international airport is the largest in Scotland and the second largest and busiest in Great Britain after London. (S. R. W.)

AYRTON, HERTHA (née MARKS) (1854–1923), English scientist, is best known for her work with the electric arc. She was born at Portsea, April 25, 1854. She enrolled in Girton college in 1876, and when she returned, studied science in London and married W. E. Ayrton, whose pupil she had been. W. E. Ayrton is known for his work in association with John Perry on electrical measuring devices, particularly the dynamometer (*q.v.*) and wattmeter. The work on the electric arc, which made Mrs. Ayrton famous, began in 1883, and her book, *The Electric Arc*, appeared in 1902. In 1903 Ayrton was asked by the admiralty to elucidate some of the problems connected with the electric searchlight. The four reports (1904–08) were largely, and the last one entirely, the work of Mrs. Ayrton. She continued to work on the problem after her husband's death in 1908, continuing at the same time her researches on ripples in water. Her discoveries in this connection she utilized in the invention of the Ayrton antigas fan for the repulsion of noxious gases in war. The first installment of these fans was sent to the front in France in May 1916. She was then asked by the war office to investigate the ventilation of gun emplacements. Toward the end of her life she experimented with the transmission of coal gas to obviate the necessity of separate gasworks in each district. She died Aug. 26, 1923.

See Evelyn Sharp, *Hertha Ayrton* (1926).

AYSÉN (AISÉN), a province of southern Chile created in 1929, when it was elevated from territorial status. The territory was formed in 1927 from parts of the present Chiloé, Llanquihue and Magallanes provinces. Pop. (1960) 37,803. Its area, 39,994 sq.mi., includes two-thirds of the Chonos archipelago (island clusters north of lat. 45° 45′ S.), the Taitao peninsula and the mainland between the Palena river and Lake San Martín (Lake O'Higgins). The Taitao peninsula-Chonos group and the Moraleda-Elephant channels, respectively, are the southern end of the submerged Chilean coastal range and longitudinal depression. To the south, as to the east, Andean structure prevails. The series of volcanoes associated with the Andes south of Santiago's latitude terminates northwest of Puerto Aysén. The mountains, which rise 3,000 to 9,000 ft., appear as rugged blocks separated by glaciated valleys and fiords. Perennial snowfields cap most elevations above 3,000 or 3,500 ft.; glaciers extend into the valleys and, in some cases, to the sea. One of the Cerro San Valentín glaciers provides an impressive spectacle at its terminus on Lake San Rafael, northeast of the Isthmus of Ofqui. The rough land at lower elevations is forested, chiefly with broadleaf evergreens. Heavy, all-year rains and uniformly cool but not cold temperatures prevail. The rivers, many of which rise to the east of the main cordillera and cross to the Pacific side, are among the most turbulent in Chile.

The few primitive nonfarming Indians who once lived in this area have all but disappeared. Replacing the coastal Indians are emigrants from Chiloé (*q.v.*) who farm patches of potatoes and wheat and comprise the labour force. On the drier Patagonian side of the province, where brush and grass vegetation is general, colonists are operating larger and more diversified farms. Sheep and cattle are numerous, many of them being raised on three large pastoral concessions which were granted by the government in 1900. Coyhaique, the largest town (pop. [1960] 8,782), Balmaceda (founded 1917) and Chile Chico are trading centres in the developing interior. The latter two have air service to Puerto Montt. The former two are joined by all-weather road to Puerto Aysén (pop. [1960] 5,488), provincial capital and port of call for the small steamers which run between Puerto Montt and Punta Arenas. Lumber, and lead, zinc and silver concentrates are produced. (J. T.)

AYTON (AYTOUN), **SIR ROBERT** (1570–1638), one of the earliest Scottish poets to use southern standard English as a literary medium, was the son of Andrew Ayton of Kinaldie, Fifeshire, and was born in 1570. He was educated at the University of St. Andrews. On the accession of James VI to the English throne he wrote in Paris a Latin panegyric which brought him into immediate favour at court. He was knighted in 1612. He held various lucrative offices, and was private secretary to the queens of James I and Charles I. He died in London, and was buried in Westminster abbey on Feb. 28, 1638. Ayton's contemporary literary reputation was considerable, although he never considered himself as a poet, but his poetry seems stilted and artificial to modern readers.

BIBLIOGRAPHY.—Ayton's Latin poems are printed in *Delitiae Poetarum Scotorum*, i, pp. 40–75 (1637). They are reprinted with his English poems and a memoir in Charles Rogers' edition of *The Poems of Sir Robert Aytoun*, 2nd ed. (privately printed, 1871). For further details of his life, *see* A. B. Grosart in the *Dictionary of National Biography*.

AYTOUN, WILLIAM EDMONDSTOUNE (1813–1865), Scottish poet and humorist whose parodies and light verse make him a forerunner of W. S. Gilbert (*q.v.*), was born at Edinburgh on June 21, 1813. He was a descendant of Sir Robert Aytoun, and his mother, who knew Sir Walter Scott well, gave him his love of ballads and Scottish history. Educated at Edinburgh academy and university and at Aschaffenburg, Ger., where he began to translate Goethe, Aytoun became a writer to the signet in 1835 and in 1840 was called to the Scottish bar. He remained a barrister in spite of his confession that "I followed the Law diligently; but, somehow or other, I never could overtake it."

His early poems, *Poland, Homer and Other Poems* (1832) were serious, and so were his first contributions to *Blackwood's Magazine* (1836); in fact he always regarded himself as primarily a serious poet. In 1849, however, he began to collaborate with Theodore Martin in a series of humorous and satirical papers for Blackwood's, in which first appeared the verses republished separately as *The Bon Gaultier Ballads* (1845). These were models for later writers, especially for Gilbert in the *Bab Ballads*. Aytoun excels in parody (*e.g.*, "The Queen in France," based on "Sir Patrick Spens," and "The Massacre of the Macpherson.")

Aytoun joined the staff of *Blackwood's Magazine* in 1844, contributing political as well as miscellaneous articles for the rest of his life. In 1845 he was appointed professor of rhetoric and belles lettres at Edinburgh university; the number of his students rose from 30 to 1,850 in a few years. Shortly afterward he published *Lays of the Cavaliers* (1848), a set of Jacobite ballads which achieved wide popularity; some, such as "The Execution of Montrose," have a grave beauty. In 1854, reverting to light verse, he published *Firmilian, a Spasmodic Tragedy*, in which the writings of Philip James Bailey, Sydney Dobell (*qq.v.*) and Alexander Smith were brilliantly ridiculed. In 1852 his services to the Tory party, especially in defense of protection, had been recognized by his appointment as sheriff of Orkney.

In 1858 Aytoun published his collection of the *Ballads of Scotland*, 2 vol., and a translation made with Theodore (then Sir Theodore) Martin of the *Poems and Ballads of Goethe* (1858). His novel, *Norman Sinclair* (1861), pictures Scottish manners in the early 19th century. He died at Elgin on Aug. 4, 1865.

Aytoun's poems were edited by F. Page (1921).

See Sir Theodore Martin, *Memoirs of W. E. Aytoun* (1867).

AYUB KHAN, MOHAMMED (1907–), president of Pakistan since 1958, was born on May 14, 1907, in Rihana village, Hazara district, North-West Frontier Province, India (now West Pakistan). His father was Rissaldar-Major (Senior Cavalry Officer) Mir Dad Khan. The family comes of ancient frontier landholding stock with a strong military tradition, and Ayub Khan claims that his background gives him an understanding of the needs and outlook of the rural masses. After attending Aligarh Muslim University he joined the army, passed out from the (British) Royal Military Academy at Sandhurst, and served with the Royal Fusiliers before joining the 14th Punjab Regiment. He saw much active service, commanding a battalion on the Burma front in World War II, before becoming president of the Services Selection Board. After independence (1947), his skilful handling of a difficult situation in Waziristan gave him promotion as major general. In 1951 he became the first Pakistani commander in chief and a national figure. In the face of great difficulties he remodeled the defense forces and improved their status, at a time when ministerial instability and rumours of widespread corrup-

tion had discredited many politicians.

In 1958, after Pres. Iskander Mirza had abrogated the constitution on Oct. 7, Ayub Khan became supreme commander and chief martial law administrator. Shortly afterward, on Oct. 27, 1958, he assumed office as president. He did much to stamp out corruption, with the help of army officers who were temporarily attached to different ministries. He thought that Pakistan needed a strong executive and that it was unfit for the party politics that had weakened previous administrations. The "basic democracies," or local elected bodies, that he established in 1960 were intended to associate the rural population more closely with the government and to exclude the politicians of the former regime, many of whom were disqualified from public office on charges of corruption. He received an overwhelming vote of confidence in 1960 and was re-elected president in 1965. *See* also PAKISTAN: *History.*

AYYUBIDS, the dynasty which ruled over Egypt, upper Iraq, most of Syria and Yemen in the late 12th and early 13th centuries. It took its name from Ayyub (d. 1172), a Kurdish chieftain from Armenia who served a vassal of the Seljuk sultan Alp Arslan and rose to be governor of Damascus. Saladin (*q.v.*), Ayyub's son, was the real founder of the dynasty. It was he who mobilized Muslim enthusiasm to build up a united front against the crusaders and made Egypt the most powerful Muslim state in the world at that time. The death of Kamil I, Saladin's gifted nephew, in 1238, marked the virtual end of the line.

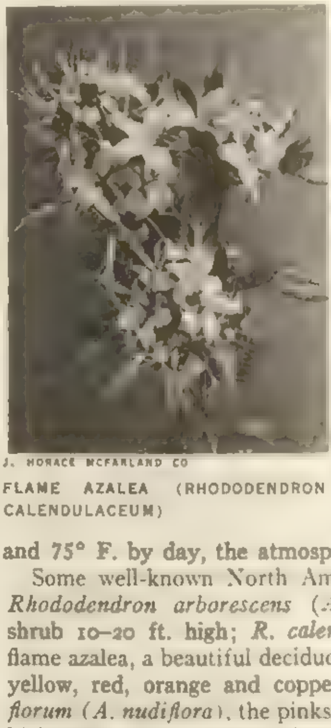
The Ayyubid regime was a decentralized, semifeudal family federation. Under a sovereign to whom all owed allegiance, territories were distributed among vassal relations who enjoyed autonomy in the internal administration of their provinces. The sultan directed the policy of the central government, which was transacted by divans of state. The most important divans were those of war, finance and public security and the chancery which was responsible for the conduct of correspondence and the drafting of treaties. Christians and Jews, who alone possessed the requisite secretarial training and who were generally well treated, carried out much of the administrative routine. The Ayyubids were zealous Sunnite Muslims who warred against Muslim Shi'ites and Christians with missionary enthusiasm and sought to convert them by means of education. The madrasah, an academy of religious sciences in which each of the four schools of Sunnite Islamic law had its own teachers, was introduced by them into Egypt and Jerusalem from eastern Islam. They treated the caliphs of Baghdad with deference and frequently invited their advice and mediation. Yet they showed a certain tolerance to non-Muslims, as when they allowed Dominicans and Franciscans to enter their dominions. Despite the ideological differences which separated the Ayyubids from their Shi'ite Fatimid predecessors, Ayyubid culture may be regarded as an extension and development of the Fatimid. Architecturally, the Ayyubids were great military engineers, as the citadel of Cairo and the defenses of Aleppo testify. The metal work of the period, inspired by craftsmen from Mosul, is excellent.

See C. Cahen, *La Syrie du Nord à l'époque des croisades* (1940) and article "Ayyubids" in *Encyclopaedia of Islam*, 2nd ed. (1958); also G. Wiet, "Les Ayyoubides," *Histoire de la nation égyptienne*, ed. by G. Hanotaux, vol. iv (1937). (R. L. HL.)

AZAÏS, PIERRE HYACINTHE (1766–1845), French philosopher remembered for the visionary optimism of his system, was born on March 1, 1766, at Sorèze in Languedoc, the son of a composer. A friendship with Sophie Cottin, the novelist, brought him into literary society under Napoleon I, and he made his name with *Des Compensations dans les destinées humaines*, 3 vol. (1809), in which he argued that happiness and misery alternate and produce a natural balance in the total of human experience. This was followed by his *Système universel*, 8 vol. (1809–12), a cosmological work in which everything—past, present and future—is "explained" in terms of expansive and compressive forces interacting harmoniously. He was given minor administrative posts and a pension, but lost these at the restoration of the Bourbons and lived in penury until the duc Decazes granted him a government pension again. Meanwhile, in collaboration with his wife, he had published *L'Ami des enfants*, 12 vol. (1816), a continuation of Arnaud Berquin's tales for children. Eventually his theory of compensations, which had proved agreeable to Bonapartist and to Bourbon regimes alike in so far as it discouraged political agitation, became the subject of ridicule. Azaïs also wrote on freemasonry (1834) and on phrenology and magnetism (1839) and published numerous analyses of political trends during the reigns of Charles X and Louis Philippe. He died at St. Émilion on Jan. 22, 1845.

AZALEA, the name still commonly used by most gardeners for certain species of *Rhododendron* (*q.v.*) that were formerly given the generic designation of *Azalea*. The azaleas are commonly described as deciduous shrubs, and this is true of the native North American species, but the Indian azaleas and others are evergreen, while some rhododendrons are deciduous. Neither the shape of the corolla nor other characters are sufficiently constant to serve as means of separating these plants into two distinct genera, although typically azaleas are deciduous while rhododendrons are evergreen, their flowers are funnel-shaped, somewhat two-lipped and often fragrant, rather than campanulate and usually inodorous as in rhododendrons, and possess typically five, rather than ten or more, long-exserted stamens. However, intermediates or intergrades occur.

The beautiful varieties in cultivation have been bred from a few originals, natives of the hilly regions of Asia and the United States. They are perhaps unequaled as indoor decorative plants. Propagation is usually done by grafting the half-ripened shoots on the stronger-growing kinds, the shoots of the stock and the grafts being in a similar half-ripened condition, and the plants then being placed in a moist temperature of 65° F. A rich and fibrous peat soil, with sufficient sand to prevent waterlogging, is required. The best time to pot azaleas is three to four weeks after the blooming is over. To produce handsome specimens, the young plants must be cut back whenever necessary.



J. HORACE MCFARLAND CO

FLAME AZALEA (RHODODENDRON CALENDULACEUM)

Specimens that have grown stringy may be pruned back just before growth commences. The lowest temperature for them during the winter is about 35° F., and during their season of growth from 55° F. to 65° F. at night, and 75° F. by day, the atmosphere being kept relatively humid.

Some well-known North American species are the following: *Rhododendron arborescens* (*Azalea arborescens*), a deciduous shrub 10–20 ft. high; *R. calendulaceum* (*A. calendulacea*), the flame azalea, a beautiful deciduous shrub two to six feet high, with yellow, red, orange and copper-coloured flowers; and *R. nudiflorum* (*A. nudiflora*), the pinkster flower, a shrub three to six feet high, with pink to nearly white flowers. *R. canadense* (*Rhodora canadensis, A. canadensis*), the rhodora, is a much-branched deciduous shrub, one to three feet high, with rose- or pinkish-purple flowers.

The Ghent azalea, *R. gandavense* (*A. gandavensis*), the Korean azalea, *R. yedoense* (*A. yedoensis*), and the Kurume azalea, *R. japonicum* (*A. kurume*), have been the parents of hundreds of named horticultural forms, which, with the North American species, are among the finest hardy shrubs in cultivation. (J. M. BL.)

AZAMGARH, a town in Uttar Pradesh, India, the headquarters of Azamgarh district, is on the Tons river, a tributary of the Gogra (*q.v.*), 53 mi. N.N.E. of Varanasi (Benares). Pop. (1961) 32,391. The Tons encloses the town on east, south and west, a danger to it in times of flood. Azamgarh was founded in 1665 by Azam Khan, a local Rajput chief, feudatory to the Mogul. The only monument of note is the dilapidated remnant of Azam's fort. Azamgarh is now a compact settlement of narrow streets, flanked by both *kucha* (mud, tile-roofed) and *pukka* (masonry)

houses. It is on the Northeastern railway metre-gauge system.

Azamgarh District is bordered on the north by the Gogra river, which is flanked by a low-lying tract varying considerably in width. South of this the ground rises slightly, then slopes away gently toward the southeast. Drainage is in general inadequate to deal with the annual average rainfall of 45 in. brought by the monsoon-type climate. The soil is alluvial and fertile; about 73% of the district's area of 2,222 sq.mi. is cultivated and most of the population (2,408,052 in 1961) depends on agriculture. Rice, sugar cane, wheat, pulses and millets are the main crops. During the rainy season malaria is prevalent, affecting the work of rice cultivation.

Road communications are confined to dry-weather unmetalled roads, apart from the Fyzabad-Gorakhpur-Varanasi main road which passes through the east of the district. The main industries are sugar refining and hand loom weaving. Mau, 25 mi. S.E. of Azamgarh, is noted for fine hand loom cloth, which is exported from the district. Mau is at the junction of the Azamgarh metre-gauge line with that running north from Varanasi. (M. N. K.)

AZAN (Adhan or Ezan), an Arabic word meaning "announcement," is the call to public worship on Friday and to the five daily hours of prayer (*salat*) in Muslim countries. The *azan* is proclaimed by the muezzin, a servant of the mosque chosen for good character, who stands at the door or at the side of a small mosque, or on the minaret (*q.v.*) of a large one. Many mosques have installed electronic recordings of the *azan*, and amplifiers have displaced the muezzin on the parapet.

The *azan* translated runs: "God is most great. I testify there is no god but God. I testify that Mohammed is the apostle of God. Come to prayer. Come to salvation. God is most great. There is no god but God." The first phrase is proclaimed four times, and the rest twice, save for the last. To the morning *azan* is added twice: "Prayer is better than sleep." The worshiper makes a set response to each phrase.

The *azan* was at first simply: "Come to prayer," but according to tradition Mohammed consulted his followers with a view to investing the call with dignity. Some advised using the Jewish trumpet, others the Christian bell, but the matter was finally settled by the dream of a certain Abdullah, which suggested summoning the faithful by the voice of a crier proclaiming: "God is most great, etc."

See K. Cragg, *The Call of the Minaret* (1956). (A. K. Cr.)

AZAÑA, MANUEL (1880–1940), Spanish statesman prominent in the politics of the second republic, of which he became president in 1936, was born on Jan. 10, 1880, at Alcalá de Henares. He was educated at the Augustinian Colegio María Cristina at the Escorial, but left it with strongly anticlerical opinions. Afterward he studied law in Paris, but his early career was mainly literary. He dabbled in journalism, translated George Borrow's *The Bible in Spain* and works by Bertrand Russell and wrote an autobiographical and anticlerical novel *El Jardín de los frailes* (1927). A biography of Juan Valera gained him the national prize for literature in 1926.

His political career began toward the end of the dictatorship of Primo de Rivera. In 1930 he was elected president of the Ateneo, a celebrated literary and political club in Madrid, from which he began to organize a republican movement. He was a member of the revolutionary committee which signed the pact of San Sebastián in Aug. 1930 and which in April 1931 became the provisional government of the second republic (*see* Spain: *History*). Azaña was the dominant figure in the constituent *Cortes* of 1931. As minister for war in the provisional government he conducted a thorough purge in the army; and during the discussions on the new constitution he was the driving force behind the articles restricting the freedom of the religious orders and permitting the suppression of the Society of Jesus. When the adoption of these articles caused the resignation of Niceto Alcalá Zamora (*q.v.*) as prime minister in Oct. 1931, Azaña became his successor.

The government soon became predominantly Socialist (though by political sentiment its members would more properly be termed Liberals), not from choice but because of the defection of the Radical leader Alejandro Lerroux. Azaña's premiership, which lasted until Sept. 1933, has been much criticized, especially for the Law for the Defense of the Republic (1931) and for the severity with which the government acted during the civil disturbances in Jan. and Aug. 1932 and in Jan. 1933. However, during a period which abounded with both Anarchist and Monarchist plots, Azaña's chief merit lay in the provision of firm government. The enthusiastic innovations of his inexperienced ministers made the years 1931–33 the most fruitful in internal reforms in the history of the second republic.

In the autumn of 1933 Azaña was driven from office by a combination of centre and right-wing parties under Lerroux. He was arrested in 1934 on suspicion of having abetted a rising in Catalonia, but the charges against him failed and he was increasingly looked to as the "strong man" who might save the republic. His decision to stand for president after the popular front's victory (Feb. 1936) and the deposition of Alcalá Zamora was therefore surprising. He was elected president on May 10, 1936. The motive for his candidature may have been a desire to prevent the left-wing parties under Francisco Largo Caballero from gaining complete control, but he was able to do little before the outbreak of civil war. His reaction to the nationalist rising—the appointment of the moderate Diego Martínez Barrio as prime minister in an attempt to widen support for the republic—was typical, but unsuccessful. Control of policy passed from his hands, and though he remained in office he was merely a figurehead. After the victory of the nationalist forces he went into exile in France, where he died, at Montauban, on Nov. 4, 1940.

AZANDE (Zande), often referred to in early travel literature as Niam-Niam, are one of the best-known Sudanic-speaking peoples of central Africa. They straddle the Nile-Congo divide, living partly in the Sudan, partly in the Republic of the (former Belgian) Congo and partly in the Central African Republic. An estimate of their population in the late 1960s put it at about 750,000. Their country, savannah in the north and rain forest in the south, is for the most part suitable for agriculture and hunting, which they diligently pursue. Eleusine (a cultivated grass, *Eleusine coracana*) is their staple crop, but they also cultivate much maize, peanuts, sweet potatoes, sesame, peas and beans, manioc, and bananas. Oil crushed from termites is an important article in their diet. They had a reputation for cannibalism in the past. The Azande are fine craftsmen in iron, clay and wood.

The Azande are ethnically very mixed. In the 18th century a people calling themselves Ambomu and living on the Mbomu river began, under the leadership of their ruling Avongara clan, to conquer vast stretches of territory to the south and east, and overcame many peoples, some of whom have preserved their languages while others have been completely assimilated. This amalgam is the Azande people of today. During their conquests also, scions of the royal clan carved out kingdoms for themselves. The king's court—in the province he ruled over directly himself—was in the centre of the kingdom, and paths ran from it to the courts of provincial governors, mostly members of the royal clan. These governors were appointed by the king and they paid him tribute and were obliged to mobilize their subjects for war at his command. For war the male population was organized into companies, which were also summoned by the king and his governors to clear their cultivations. There were frequent full-scale wars between kingdom and kingdom and border raids took place every year.

The traditional distribution of the Azande is in widely scattered homesteads, each the residence of a family. Polygyny is practised, and in the past many men, especially the nobles, had so many wives that it was difficult for the younger men to marry. Adultery could be heavily punished. Marriage was contracted by the gift of about 20 spears by the bridegroom to the family of the bride. Girls were married very young and sometimes affianced a few hours after birth. While the commoners will not marry into their own clans, the nobles often marry kinswomen, even their paternal half sisters and their own daughters. Patri-

lineal clans are numerous but widely dispersed and have only very general social functions. These clans are totemic, and it is believed that at a man's death the body-soul, one of the two souls the Azande credit themselves with, becomes a totemic animal of his clan.

Zande religion is an ancestor cult, the conception of a god being vague and relatively unimportant. More significant for them, however, than the cult of ancestors, is witchcraft. They devote much time, when they have suffered misfortunes, to discovering who is bewitching them. In their view misfortunes, especially sickness and death, are caused by witches motivated by malice; and the witch responsible is discovered by administering poison to fowls and, in the past, sometimes to human beings also, and putting the names of suspected persons before the poison, asking it to declare their guilt or innocence by killing or sparing the fowls. In the past a witch who killed a man was either speared or made to pay compensation, or magic was made by the dead man's kin to destroy him. Only the last method of exacting vengeance is used today.

Baxter and A. J. Butt, *The Azande and Related Peoples of the Anglo-Egyptian Sudan and Belgian Congo* (1954). (E. E. E.-P.)

AZARIAH (Azarias): *see* Uzziah.

AZARIAH, VEDANAYAKAM SAMUEL (1874–1945), the first Indian bishop of the Anglican Church in India, was born on Aug. 17, 1874, at Vellalanvilai in the Tinnevelly district of south India, where his father was the parish priest. He worked with the Young Men's Christian association and with the Indian Missionary society of Tinnevelly, which he had helped to found in 1903. He was ordained in 1909, and on Dec. 29, 1912, earlier opposition having been overcome, he was consecrated bishop of Dornakal. At first he had charge only of the small area of the Indian Missionary society; but, as he grew in experience and power, his area was increased until it included all the Telugu-speaking districts of the Madras presidency in which the Anglican missions were at work, an area containing 100,000 Christians by 1930. As bishop, Azariah developed remarkable powers as writer, preacher, teacher and organizer.

For many years he played a great part in wider Christian movements. At the World Missionary conference in Edinburgh in 1910, he delivered a memorable address on relations between missionaries and national workers. He was chairman of the National Christian Council of India, Burma and Ceylon from 1929 to 1945. For more than 20 years he was a leader on the Joint Committee on Church Union in South India, but died on Jan. 1, 1945, at Dornakal, too early to see the inauguration of the Church of South India in 1947.

See C. Graham, *Azariah of Dornakal* (1946); introduction by S. C. Neill to V. S. Azariah, *Christian Giving* (1955). (S. C. N.)

AZAY-LE-RIDEAU, a town of central France in the *département* of Indre-et-Loire, lies a few miles above the confluence of the Indre with the Loire rivers 15 mi. S.W. of Tours. Pop. (1962) 1,661. The château, built in 1518–27 by Gilles Berthelot the financier as his country house, is partly constructed on piles and projects out over the Indre river. Surrounded by a wooded park, it is an elegant Renaissance building, two stories high, forming two sides of a square; the other sides were never built. Turrets with sharply pointed roofs mark the three corners. The main façade was sculptured by Pierre Maupoint and its chief features are two emblems—the salamander of Francis I and the ermine of Claude of France—accompanied by mottoes. Inside there is a beautiful staircase in Italian style and the rooms contain 17th-century furniture and many works of art. The spectacle of *Son et Lumière* is presented in the grounds in the summer. The town is built at the foot of a hill by the Indre, and its old streets are narrow and tortuous. The parish church, at one corner of the park, dates from about 1000. Azay-le-Rideau is in a fertile district which produces white wine, pears and, particularly, apples. Veneer work, panelling, and boxes for dairy produce are made. Originally the site of a Roman villa, the town was known in the 12th century as Azayum and in 1213 the chatelain was Hugues-le-Ridel. Burned down in 1418, it was called Azay-le-Brûlé (burned) until the 16th century. Since about 1885 the château has belonged to the state.

(O. S.; P. So.)

AZEGLIO, MASSIMO TAPARELLI, Marchese d' (1798–1866), Italian statesman, painter and author, an honest patriot of the Risorgimento and a good example of the best type of Piedmontese aristocrat, was born in Turin on Oct. 24, 1798. In Rome, where his father was special envoy from the kingdom of Sardinia to the Vatican, he acquired a love of art and music and became an artist, even holding exhibitions in Paris and London. From 1831 to 1843 he lived in Milan in order to escape the authoritarian and philistine atmosphere of Turin. There he married a daughter of Alessandro Manzoni and turned to literature. His writings, whether novels or pamphlets, aimed at exposing the evils of foreign domination in Italy and awakening the national consciousness. They also had a considerable impact in France and England.

D'Azeglio fought in the first war of Italian independence in 1848 with the papal forces against Austria. In 1849, in Turin, he formed the first cabinet under Victor Emmanuel II and concluded peace with Austria. He remained in office for three years. He conducted the affairs of Piedmont with tact and ability, improving its diplomatic relations and introducing the important Siccardi laws of 1850 which abolished ecclesiastical courts and immunities. He invited Cavour, then a rising young politician, to enter the ministry in 1850. Cavour made certain declarations in the chamber (May 1852) which led the ministry in the direction of an alliance with Urbano Rattazzi and the left. D'Azeglio disapproved of this and therefore resigned office, but on the king's request he formed a new ministry, excluding Cavour. In Oct. 1852, however, he retired into private life. For the next four years he lived modestly in Turin, devoting himself once more to art, although Cavour treated him as an elder statesman and sometimes, because of D'Azeglio's fine reputation abroad, consulted him on matters of moment. In 1855 he was appointed director of the Turin art gallery. In 1859 he was given various political missions, including one to Paris and London to prepare the basis for a general congress of the powers on the Italian question. When war between Piedmont and Austria appeared inevitable he returned to Italy and was sent as royal commissioner by Cavour to the Romagna, whence the papal troops had been expelled. After the armistice of Villafranca, D'Azeglio was recalled with orders to withdraw the Piedmontese garrisons, but he saw the danger of allowing the papal troops to reoccupy the Romagna and after a severe inner struggle left the Piedmontese troops in Bologna. The king approved of this and explained that his orders had not been accurately expressed; thus Piedmontese influence continued to prevail in the Romagna, and the ultimate annexation of this area was prepared. Early in 1860 Cavour appointed D'Azeglio governor of Milan after the annexation of Lombardy. D'Azeglio disapproved, however, of the government's policy with regard to Garibaldi's Sicilian expedition and of the occupation by Piedmont of the kingdom of Naples (which he regarded as inopportune) and so resigned office. He subsequently led a comparatively retired life. As deputy and as writer, he occupied himself chiefly with the Roman question. In his opinion Italy should be unified by the Piedmontese and French armies, all connection with Mazzini and the Italian nationalist conspirators being eschewed. The pope should enjoy nominal sovereignty over Rome, with full spiritual independence, the capital of Italy being established elsewhere but the Romans being Italian citizens. Naples and Sicily, he thought did not want Italian unity and should be given their independence.

D'Azeglio died at his villa of Cannero on Jan. 15, 1866, leaving his memoirs, *I miei ricordi*, unfinished. He was cautious and conservative and was to some extent an amateur in politics, but of his sincerity there is no doubt. His political writings are trenchant and clear, but his novels, *Ettore Fieramosca* (1833) and *Niccolò dei Lapi* (1841), are somewhat heavy and are interesting only if one understands their political allusions.

See A. Vismara, *Bibliografia di Massimo d'Azeglio* (1878); N. Vac-

calluzzo, *Massimo d'Azeglio* (1925). (D. M. Sh.)

AZERBAIJAN (Āzarbāījān), formerly the Northwestern province of Iran, was subdivided in 1938 to form the Third and Fourth *ostans* (provinces), later East and West Azerbaijan, with capitals at Tabriz (*q.v.*) and Rezaiyeh respectively. With a combined area of 44,108 sq.mi., it is bounded north by the Aras river separating it from the Soviet republics of Azerbaijan and Armenia; west by Turkey and Iraq; east and south by the Iranian First (Gilan), Fifth (Kermanshah) and Kurdistan *ostans*. The region has high ranges and ancient volcanoes, like Savalan (Sabalan) (15,784 ft.) and Sahand (12,138 ft.), dominating extended plateaus and fertile depressions ranging from 3,000 to 5,000 ft. above sea level. The climate is extreme, hot, relatively dry summers alternating with cold, snowy winters. Annual precipitation varies from 12 to 35 in., permitting dry farming. There are no natural forests preserved except on the Caspian slope near Astara.

Modern excavations have shown that Azerbaijan was a centre of early civilization. It formed part of Urartu and later of Media (*qq.v.*). It was conquered by Alexander the Great and named Atropatene after Atropates, one of his generals who founded a dynasty. It returned to Persian control under the Sassanians (A.D. 226). Invaded by Arabs, Turks and Mongols it was the cradle of the Safawid dynasty. During early Qajar times (18th–19th centuries) the Russians gradually encroached on the Transcaucasian dependencies and before World War I and again during World War II (when the province was occupied by Soviet troops) virtually dominated the province. In Nov. 1945 a communist-led revolt resulted in an autonomous republic's being established in Tabriz and a Kurdish one at Mahabad. On Dec. 11, 1946, Iranian control was re-established.

The population was 2,112,134 (East) and 878,797 (West) in 1961, chiefly Iranian Turks, Kurds, some Armenians, Assyrians, Jews and Persians. Azeri-Turkish, the language of the majority, differs from the idiom of Turkey. The Turks of Azerbaijan are Shi'ites and the Kurds are Sunnis. There are still nomadic groups among the Turks and Kurds, the largest being the Shahseven, who are believed to number more than 100,000 and migrate between the Moghan steppe and Mt. Sabalan.

The best agricultural lands are around Lake Rezaiyeh (Urmia), a shallow, highly saline lake covering from 1,750 to 2,300 sq.mi. according to the season. Cereals, fruits, cotton, tobacco and sugar beets are grown and dried fruits are exported. Azerbaijan sheep are famous for their wool. There are scattered deposits of copper, lead, iron, coal, salt and orpiment, and traces of petroleum. The commercial centre is Tabriz which once rivaled Teheran. Famous for its carpets, it is now linked by rail with Teheran and, through Jolfa, with the Soviet system. Regional centres are Maragheh, Urmia (Rezaiyeh), Ardabil, Khoi (Khvoy) and Mahabad (Saujbulagh). (H. Bo.)

AZERBAIJAN SOVIET SOCIALIST REPUBLIC (Azerbaidzhan), one of the three soviet socialist republics in Transcaucasia (Georgia, Armenia, Azerbaijan), covers the extreme southern part of European U.S.S.R. lying beyond the Greater Caucasus (Bolshoi Kavkaz) mountain range. Azerbaijan is 33,436 sq.mi. in area and had (1959) 3,697,717 inhabitants. The republic is of special importance to the Soviet Union, both for its cotton and oil and because of its position at the gateway to Iran and southwest Asia.

Geographical Characteristics.—Azerbaijan may be divided into four major physical regions from north to south. The north comprises the eastern end of the Great Caucasus range, exceeding 14,000 ft. in the peak Bazar-Dyuzi but dropping steeply southeastward into the Caspian to form the Apsheron peninsula (Apsheronski Poluostrov). The southern flank of the Caucasus overlooks the second main region of Azerbaijan, the Kura-Aras lowland (Kura-Araksinskaya Nizmennost). This is the eastern end of an almost continuous depression drained in Azerbaijan by the Kura river and its tributaries. It extends from the Black sea to the Caspian between the Greater and Lesser Caucasus (Malyy Kavkaz). Toward the southeast the lowland widens and levels out, ending at the Caspian sea in the Kura delta. In the south-

AZERBAIJAN SOVIET SOCIALIST REPUBLIC, INCLUDING THE NAKHICHEVAN AUTONOMOUS SOVIET SOCIALIST REPUBLIC AND THE NAGORNO-KARABAKH AUTONOMOUS OBLAST

west of the republic the Kura lowland is limited by the third region, the ranges and plateaus of the Lesser Caucasus, with many small areas exceeding 10,000 ft. The Nakhichevan Autonomous Soviet Socialist Republic, U.S.S.R., separated from the rest of Azerbaijan by part of Armenia, comes within this region and is drained by the Aras (Araks) river. The fourth region is the small, narrow Lenkoran lowland (Lenkoranskaya Nizmennost) squeezed between high mountains and the Caspian sea.

Partly because of the great range of altitude in the republic, there is a great variety of climate, vegetation and soil conditions. It lies mainly between latitude 42° and 39° N. and is officially classified as dry subtropical. There is a considerable range of temperature between summer and winter, Baku having a mean January temperature of 39° F. and a mean July temperature of 78°. Mean annual temperatures decrease with altitude in the mountain regions. Mean annual precipitation tends to increase with altitude, being less than 10 in. at the mouth of the Kura, 10–15 in. in the Kura valley, but more than 40 in. in the highest part of the Greater Caucasus. The small Lenkoran lowland has the exceptionally high figure of 40–50 in. Natural vegetation and soil zones vary according to altitude, with steppe and even semidesert conditions in the lowland and foothills of the mountain regions and an intermediate zone of broadleaf forest below the high zone of Alpine meadows. The luxuriant vegetation of the Lenkoran lowland contrasts with the generally thin cover of vegetation elsewhere in the republic.

Wild animals abound in the Greater Caucasus range including, in the forest zone, the Caucasian deer (*Cervus elaphus maral*), wild boar (*Sus scrofa attila*), bears, wolves, foxes, leopards and the lynx (*Felix lynx orientalis*), wild cats and jackals. Above the forest the chief fauna are wild goats and eagles. In the lowland there are porcupines, antelopes, hyenas and tigers, as well as many rodents. In the humid Lenkoran lowlands waterfowl are numerous.

Population.—The Azerbaijan S.S.R. includes two smaller administrative units, the Nakhichevan A.S.S.R. (*q.v.*) and the Nagorno-Karabakh autonomous *oblast* (A.O.) (*q.v.*). Results of the population census in 1959 were as follows:

Urban and Rural Population (1959)

Administrative unit	Total	Urban	Rural	% Urban
Azerbaijan S.S.R.	3,697,717	1,767,270	1,930,447	47.8
Nakhichevan A.S.S.R.	141,361	38,274	103,087	27.1
Nagorno-Karabakh A.O.	130,406	26,973	103,433	20.7

Only 67.1% of the population of the republic is made up of Azerbaijanis (Azers or Azerbaijani Turks) and these are con-

centrated in the Kura lowland. Russians, Belorussians and Ukrainians make up 10.3% of the total and are most numerous in Baku (*q.v.*). Armenians are another large element (12% of total population) and account for about 90% of the population of the Nagorno-Karabakh A.O. The Talyshy and Taty are other minority groups. Density of population varies from a few persons per square mile in the higher mountain areas to about 100 per sq.mi. in irrigated areas of the lowland and 200 per sq.mi. around Baku.

Of the total population of Azerbaijan, 47.8% lives in urban types of settlement, a proportion about the same as the national average. Greater Baku, with 971,058 inhabitants (1959), has more than half of the urban population and is among the largest towns in the U.S.S.R. Kirovabad (*q.v.;* 116,122) is the only other town with more than 100,000 inhabitants, but Sumgait, Mingechaur and Dashkesan are growing rapidly. Nakhichevan (25,340) and Stepanakert (19,703) are the capitals of the two small units within Azerbaijan.

About 40% of the employed population of Azerbaijan is engaged in agriculture, while the mining and industrial side of the economy is dominated by the oil industry and associated activities. Baku is the administrative and commercial capital of the republic. It is also the cultural centre, with the state university (1950) and a number of technical and cultural institutes. Kirovabad is the main urban centre of the interior.

The Economy.—There is a single Council of National Economy for the whole of Azerbaijan. Agriculture may be divided into two types: that which produces for regional consumption or Transcaucasia as a whole, and that which specializes in the production of crops, not widely grown in the U.S.S.R., for national distribution. Of the total area of the republic, about one-seventh or 3,150,000 ac. is sown, while much of the remainder is lowland or mountain pasture. Part of the sown area is irrigated (*see* map), mainly by the Kura and its tributaries. Azerbaijan produces wheat (1,340,000 ac.), barley, maize and potatoes largely for its own use. These are grown mainly on nonirrigated land on the lower slopes of the mountain regions. Cotton for use in the textile mills of the Moscow industrial region is the chief special crop. It occupies a considerable part of the irrigated land, which is also used for rice cultivation (only a small part of the area indicated on the map is actually irrigated). Other special crops of Azerbaijan are tea and citrus fruits cultivated in the Lenkoran lowlands and vines, fruits, tobacco and vegetables on the lower slopes of the Caucasus. Pastoral activities dominate the nonirrigated steppe and semidesert lands of the Kura lowlands and a certain amount of transhumance takes place between winter pastures in these lowlands and adjoining high mountain summer pastures.

In the early 1960s the republic had more than 1,370,000 cattle and 4,280,000 sheep. Meat and wool are among products sent outside the republic. In the vicinity of Baku emphasis is on the production of milk and vegetables for the large urban market.

Oil is by far the most important single commodity in the economy of Azerbaijan. Around 1900 the Baku area together with smaller oil fields in the Caucasus accounted for about half of the world's oil output; most was exported to foreign countries. It remained the chief producing area of the U.S.S.R. until the early 1950s, but since then with the growth of the Soviet economy has been largely eclipsed by the new Volga-Ural oil field known as Second Baku (*q.v.*), in which production costs are claimed to be three or four times lower than around Baku. Oil production in 1913 was 8,453,539 short tons or 75% of the national total. From a peak figure of 24,405,231 (68% of the Soviet output) in 1940, production by the late 1950s had steadily declined to below 20,000,000 short tons which compared with the output of other Soviet oil fields and represented less than 15% of the national total.

The main producing area in Azerbaijan is the Apsheron peninsula but there are smaller fields at the mouth of the Kura and near Kirovabad.

Oil is the principal source of energy in Azerbaijan, but in 1954 a large hydroelectric power station was opened at Mingechaur on the Kura. Other minerals include copper (Kedabek and Dostafyur), alunite (Zaglik), cement rocks (near Tauz) and rock salt (Nakhichevan). Baku has a wide range of industries, oil refining remaining the most important. The opening of steel, aluminum and rubber works at Sumgait near Baku after World War II stimulated the manufacture of industrial equipment especially for use in the oil industry. Other branches of industry represented in Azerbaijan are food processing, cotton ginning and the manufacture of cotton and woolen textiles, but the republic accounts for only 1%–2% of the total Soviet output of the last items. Iron ore from Dashkesan is sent to the Rustavi iron and steel works (in the Georgian S.S.R., about 20 mi. beyond the republic boundary), which serves all three Transcaucasian republics. Fisheries centred on the Caspian sea (*q.v.*) are important.

Rail is the main form of transport within Azerbaijan. Most of the oil sent from Azerbaijan to other parts of the U.S.S.R. goes across Transcaucasia by pipeline to Batumi (*q.v.*) on the Black sea or direct by water from the port of Baku to the Volga for distribution over a large part of European U.S.S.R. (J. P. Co.)

History.—The Azerbaijan S.S.R. and the Persian province of Azerbaijan adjoin each other and the origin of the peoples of both regions is broadly the same. Yet they have never been united politically except in the sense that from the 11th century up to 1723 and again from 1735 to 1813 the whole territory was either under Persian suzerainty or actually part of the Persian empire. Known to the Romans as Albania and to the Arabs as Aran, Azerbaijan was conquered by the Arabs in A.D. 642. The population had originally been Iranian but became turkicized by the 9th century (*see* TURKIC PEOPLES). Under the Arabs the various khanates—Shirvan, Aran and Mughan—became prosperous, but they deteriorated after the collapse of the Arab empire. During the Mongol domination (1236–1498) and the Safawid dynasty of Persia, the khanates, especially that of Shirvan (Shemakha), recovered some of their former prosperity. The 18th century saw the military rise of Russia and its territorial expansion at the expense of Turkey and Persia. As a result of long wars of aggression Russia acquired by the Treaty of Gulistan (1813) the khanates of Derbent, Baku, Shirvan, Sheki (Nukha), Ganja or Gandzha (now Kirovabad) and Lenkoran, and by the Treaty of Turkmanchai (1828) Nakhichevan and the southern part of Talish. Thenceforward Azerbaijan was divided between Russia and Persia by the present-day frontier, the majority of the Azerbaijanis remaining in Persia. Under Russian rule the Azerbaijanis were called Tatars or Musulmans and they were administered in the guberniyas of Baku and Elizavetpol.
